Mr. Lamont gives a minute description of the construction of his admirably built steam yacht the *Diana*, which came unscathed through many dangers. In 1869 he sailed as far as the Kara Straits, which he did not enter. Next year, however, he passed through Pet or Jugor Straits, and penetrated a short distance into the Kara Sea, coming out by the Kara Straits. He sailed up the west side of Novaya Zemlya as far as Admiralty Peninsula, and after several trials succeeded in passing through the Matoschkin Schar. He landed on several points of the island, and gives some valuable notes on the fauna and flora which he observed. In 1869 he sailed along the edge of the ice-pack a little north of the 75th degree of latitude, to Spitzbergen, the coasts and gulfs and islands of which in his various voyages he has examined with great minuteness, and contributes several notes on the physical geography and natural history, which will be found of value as supplementary to those of other observers. Regular temperature soundings were taken and the surface-temperature observed, the condition and movements of the ice noted, especially in the Kara Sea, as well as any evidences of currents; and Mr. Lamont's observations on these points, and especially on the movements of the ice in the Kara Sea, we would recommend to the notice of all interested in Arctic physics and Arctic geography. Mr. Lamont has a right to be considered an experienced Arctic observer, and his opinions should be received with respect. Years ago he conjectured that land should be found to the north between Spitzbergen and Novaya Zemlya; the Payer-Weyprecht Expedition has confirmed this conjecture. He tried hard to get at least a sight of Wiche's Land, but failed, though the Norwegian captains succeeded in reaching it in 1872; for there is no doubt that Petermann's King Karl Land is that discovered by Edge 250 years ago. Mr. Lamont thinks it possible that it may be connected with the recently-discovered Franz Josef Land.

Mr. Lamont records not only his own observations, but, being well up in the literature of the exploration of the region he visited, gives many valuable notes of the work done by previous explorers, as well as by some who have been there since his last voyage. We would recommend to naturalists his observations on the differences between the reindeer of Spitzbergen and that of Novaya Zemlya; the former he thinks identical with the wild and tame deer of Norway and Lapland, whereas the Novaya Zemlya type appears to him more allied to the reindeer of the American Continent. His theory as to the migration of the Spitzbergen type is very remarkable.

There are many illustrations throughout the work, some of them not well drawn, but all of them helping the reader to realise what is to be seen in the regions to which they refer. Various maps and outlines of coasts add to the value of the work, which we assure our readers they will find full of entertainment and information.

OUR BOOK SHELF

Die Neuere Schöpfungsgeschichte nach dem gegenwärtigen Stande der Naturwissenschaften. By Arnold Dodel, Privat-docent at Zürich. (Leipzig: Brockhaus, 1875.)

ANOTHER work on Evolution, equalling the "Origin of Species" in size. The author of these twelve lectures has carefully studied every important work on the subject, and endeavours to give a plain and intelligible account of Evolution in relation to the whole field of biology. The style of the work is vigorous and combative, and considerable success in exposition is attained. But many definite conclusions are announced where the most far-seeing evolutionists would only put forward tentative hypotheses. We think it will be far more advantageous for German or other students who have any real knowledge of biology to study for themselves Mr. Darwin's works than to take a less efficient, though an honest and accomplished guide in Dr. Dodel. The book is well illustrated with engravings of interesting structures in plants and animals bearing on Evolution; it also contains a

number of hypothetical scenes illustrating the fauna and flora of the past, as well as several phylogenetic trees.

Le Valhalla des Sciences Pures et Appliquées. galerie commémorative et succursale du conservatoire des Arts et Métiers de Paris, a créer dans le Palais Neuf de Mansart, au Château de Blois. Par le Cte. Léopold Hugo. (Paris, 1875.)

THE four names of Watt, Fulton, Stephenson, and Denis Papin, inscribed on the roof of the railway station at Blois, suggest a train of thought to the author in connection with the triumphs of steam and its applications. Having previously described the Château de Blois, the writer puts forward a proposal (sometimes he calls it a dream) to turn the now abandoned château into a noble valhalla of science. A principal feature is a statue of Papin (born at Blois about 1650); there should be also statues of other scientific writers of all time and climes, appropriate inscriptions, portraits on the walls, and representations of interesting scenes in the history of science, chambers for the exhibition of models and instruments, a scientific library, and other matters. So his dream is to make this a Versailles of science. A classification of the sciences and a plan close this part of the pamphlet. We do not, however, concern ourselves here with this proposal or dream or whatnot, but pass on to a brief glance at the three appendices. The first is "Definition de la double-tendance Philosophique de la Science." Noting the objects the "immortal" Bacon had in view in his New Atlantis, he applies himself to the consideration of what is the classification that we can make of the sciences, and combats Auguste Comte's arrangement according to the increasing complexity which appears inherent in them. In our author's eyes all sciences have the same complex character (caractère de complication) either virtually or actually. Comte begins with mathematics, Hugo exalts them to a high place: "L'intérêt philosophique des sciences mathématiques est de marcher à la rencontre des sciences naturelles. Il n'y a rien là qui ressemble à une subordination des certaines sciences." The second is "Examen géométrique sommaire des orbites planétaires (ovhélites)." The writer remarks that recent discoveries in Astronomy have pointed to a new movement of the solar system in space, hence the orbit or trajectory of our planets is not a plane curve. This orbit is a helicoidal curve with an elliptical or oval projection. Hence ov-hél-ite. In the geometrical description of such a curve we must indicate whether the trace is *dextrorsum* or *sinistrorsum*. The ovhélites of the planets and of the earth are geometrically traced *sinistrorsum*. In this paper, which was originally communicated to the Mathematical Society of Paris, the author states the theorem "Les ovhélites planétaires sont tracées sur les cylindres à section droite elliptique (sauf perturbation) ou du moins ovalaire. Une des lignes focales des susdites ovhélites est commune; cette ligne est la trajectoire solaire." The third appendix is "Base scientifique de la numération décimale." We will again let the Count speak for himself, "Je propose aujourd'hui d'utiliser une des plus anciennes et des plus curieuses théories de la géométrie, restée jusqu'à ce jour sans emploi, pour établir un lien entre la géométrie et l'arithmétique, en donnant comme base à cette dernière science un *nombre absolu et éternel.*" The five regular solids were treated of by Pythagoras. Cauchy and Poinsot have added to these four stellated polyhedra. "En y joignant à mon tour la sphère (qui est le régulier infinioïdique) j'arrive à constituer géométriquement le nombre infranchissable de DIX." Thus we see there is a resemblance between the nine digits and zero on the one hand and the nine regular polyhedra and the sphere on the other. Further, there is a curious feature, there are five primes among these, and there are five regular convex solids. Such then is "la conception philosophique et vraiment scientifique du nombre fondamental DIX." After two thousand years we have arrived at an application of the theory of the regular figures, there is hope also of establishing a rival to Euclid. A commission was appointed in March of last year to pronounce upon the Hugodecimal theory. "De la propriété régulière essentielle de l'espace, de l'absolu régulier, avoir fait jaillir le nombre DIX!" These are the principal points of interest in the pamphlet.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

The Article "Birds" in "Encyclopædia Britannica"

IN reply to Prof. Huxley's letter of last week with reference to my review of the article "Birds" in the "Encyclopædia Britannica," I may mention that it is to the illustrious Nitzsch, as far as I am aware, that we owe the combination of the Swifts and the Humming Birds into a single family. Burmeister's edition of Nitzsch's "Pterylography" was published in 1840, and in Mr. Sclater's translation of that invaluable work (p. 86) we read, under the heading MACROCHIRES, "In this family I place the two genera, *Cypselus* and *Trochilus*, which indeed present but little external similarity, but are very nearly allied in the structure of their wings."

In 1867, the year in which Prof. Huxley promulgated his Classification of Birds, the palatal structure of the Humming Birds was imperfectly known, as may be gathered from the following passage in his memoir * with reference to the Cypselomorphæ:—"The vomer is truncated at the anterior end, and the maxillo-palatines are slender and disposed nearly as in the typical Coracomorphæ (? *Trochilus*)." I believe that, at that time, no accurate account of it had been given by anyone.

When, in 1873, after I thought that I had fairly mastered Prof. Huxley's classification, Mr. Parker kindly informed me verbally that from his investigations on the subject he had discovered that the vomer of the Trochilidæ is sharp-pointed instead of being truncated. Upon re-reading Prof. Huxley's data for his division of Carinate birds in the Schizognathæ and the Desmognathæ, in both which groups the vomer is *pointed* (or not ossified), and the Aegithognathæ, in which the vomer is *truncated*, I naturally was led to see, as Mr. Parker has since stated in print,† that the Trochilidæ are not Aegithognathous, but Schizognathous; and I further inferred, justly I believe, that if Prof. Huxley had, in 1867, known that the vomer of the Humming Birds is sharp-pointed instead of being truncated, he would never have placed the Trochilidæ among the Aegithognathæ, for in so doing he would have been compelled to have given up the only common character of any importance which links together that group. When, therefore, I say in my review that "Professors Huxley and Parker place them [the Swifts and the Humming Birds] in quite different divisions," there can be no objection to my including Prof. Huxley's name with that of Mr. Parker in a *general* remark which is so fully borne out by the spirit of the classification introduced by the first and adopted by the second of these illustrious biologists.

That Prof. Huxley did, in 1867, adopt Nitzsch's combination of the Swifts with the Humming Birds, I would not attempt to deny, but *then* the palatal structure of the latter sub-family was not correctly known.

10, Harley Street — A. H. GARROD

The Difficulties of the Public Analysts

HAVING for some time past watched with painful interest the prosecutions under the new Adulteration Act, and seeing very clearly that whatever may be its success or failure in reference to its intended object, this Act of Parliament is becoming eminently successful in bringing chemical science into contempt, I am glad to see that you have taken up the subject in the columns of NATURE. I hope that it will be freely discussed. It may be safely affirmed that in the majority of cases where the vendor has made an effort to defend himself he has been able to flatly and positively contradict the certificate of the public analyst by counter-certificates of other analysts of equal or superior eminence. The butter case you have quoted is no exception, but may be taken as about a typical or average sample of such prosecutions. If this deplorable state of things is to continue,

* Proc. Zoolog. Soc. 1867, p. 468.
† Trans. Zoolog. Soc. vol. ix. p. 292.

the general public will be perfectly logical in concluding that either the public analysts are generally incompetent, or that chemical analysis is self-contradictory, and therefore worthless. The subject is one that seriously affects the dignity and general interests of science.

Much of the blundering that has unquestionably occurred is doubtless due to the peculiar position of public analysts and the impossibilities they are called upon to perform. The political economist tells us that "demand for commodities induces a corresponding supply," and the Adulteration Act was evidently framed upon the assumption that analytical skill is a "commodity" subject to this law, as it demanded the immediate creation of a whole army of chemists endowed with a peculiar kind of knowledge and skill, which was not to be acquired in any college, school, university, or other educational institution, public or private, in Great Britain. Laboratories existed wherein the analyses of acids, bases, and salts, organic and inorganic, were carefully taught, and others where special attention was devoted to pharmaceutical preparations; but where (before the passing of this Act) could a student find a laboratory in which he might learn how to analyse the multitude of articles that pass over a grocer's counter, and acquire the *commercial* knowledge which is as necessary to the public analyst as analytical skill? I use the past tense here, knowing that since the passing of the Act many public analysts have industriously and meritoriously availed themselves of the opportunities afforded at one laboratory that has been specially devoted to the useful purpose of affording them the special analytical skill they should have possessed before obtaining their appointments. There do not, however, appear to be any sufficient means provided for the commercial and technological education of public analysts.

As an example of the necessity of commercial or technical knowledge, I need only refer to the discoveries of "iron filings" in tea which were so common until lately, the absurdity of which I have already demonstrated by simply calculating the number of tons of iron filings that would be annually required for the alleged adulteration, and showing the practical impossibility of obtaining such a supply, either here or in China. Iron was found in the tea unquestionably,—the chemistry was not at fault,—but the theory which confounded accidental impurity with wilful adulteration arose from lack of technical knowledge, the possession of which would have shown that leaves carelessly gathered and thrown upon the dusty ground of a highly ferruginous soil, and then roasted, must of necessity be mingled with more or less of magnetic oxide of iron, besides the iron naturally contained in the ashes of this particular plant.

The series of butter cases, of which the one you quote is only a recent and ordinary example, illustrate the same want of trade knowledge on the part of nearly all concerned. I have been surprised at the repeated and uncontradicted assumption that butter must be adulterated because it is cheap, which has run through all these cases. We all know that good butter at this season is not obtainable at less than 1*s*. 8*d*. per lb., and much is sold at 2*s*., and therefore it is inferred that if butter is offered for sale at 10*d*. or 1*s*. it must be adulterated. This is a very plausible inference, but nevertheless a great mistake, which public analysts and sitting magistrates have evidently shared with the general public. But for irritating old sores, I might quote from early prosecutions, and show how an inspector and public analyst have evidently been so biassed and deceived by the simple fact that butter was offered for sale at 8*d*. per lb., and that the analyst interpreted equivocal analytical results according to such preconceptions. Had he known that parcels of *genuine* butter, sometimes amounting to several tons, are occasionally offered as low as 7*d*. per lb. in wholesale markets, this erroneous preconception would not have been formed. I have eaten butter made in some of the primitive peasant-dairies of the North of Europe, which if imported to this country would not sell at so good a price as "P. Y. C." (Petersburgh yellow candle) tallow. It was perfectly genuine and detestably nauseous, but nevertheless was highly relished by the people who made it, and to whom it forms a staple article of food, especially in winter. Such butter is occasionally shipped to England from Kiel and other Northern ports; also from Canada and Australia, and sells at ruinous prices; the merchants who send it being unacquainted with the fastidiousness of English palates, and supposing that what is eaten in their own country will be eaten here.

It is the choice brands of "fresh" butter that are the most adulterated, and those delicately-constituted people who cannot eat salt butter, but insist upon having fresh grass butter in the midst of winter when no grass is growing, are abundantly regaled with refined mutton suet, P. Y. C. tallow, candle ends, and kitchen stuff which, when skilfully prepared, churned up with a little milk and sugar and prettily rolled, moulded or packed in rustic-looking baskets, sells at 2*s*. per lb. in the west-end, and progressively down to 1*s*. 8*d*. or 1*s*. 6*d*., proceeding further eastward.

Knowing that this class of butter is systematically adulterated at this season with refined fats, you may judge of my respect for the skill of the public analysts when I find that it has escaped the prosecutions that have fallen so heavily upon the cheap butters. Taking the facts as they have come out in these prosecutions, it appears that *at present* chemical analysis fails to distinguish between the fat which is excreted from the udder of the cow, and that which is deposited in the tissues of the same animal or of the sheep, provided both are mechanically prepared in a similar manner and flavoured with a little sugar and caseine. I may possibly be wrong in this conclusion, and therefore propose a test which may be used to decide this question. Let samples be made and certified by first churning pure milk, then mixing such churnings with varying proportions of foreign fats prepared as those manufacturers can, who have converted their soap-boiling into butter-frying plant, and let such samples be sent to Mr. Muter, or any other expert who believes himself able to certify to the purity or impurity of butter. If he can determine the *percentage* of foreign fat in such varied mixtures his future certificates will have considerable value and authority.

W. MATTIEU WILLIAMS

Science in Hastings

I HAVE just seen your comments (vol. xiii. p. 217) on a letter that appeared a few weeks ago in the Hastings and St. Leonards *News*, and at once write to vindicate the honour of Hastings. We have a Philosophical and Historical Society, a Literary and Scientific Institution, and a Mechanics' Institution, besides two or three others of a more private character. A museum we certainly do not possess, and if it should prove like most *local?* museums, a collection of "et cetera," trying to rival the British Museum in the extent of its field of research, and an overturned workbox as to arrangement, the longer we are without it the better. Far be it from me to say that the people of Hastings and St. Leonards display as much interest as they ought in the pursuit of science, but still they are not so bad as you make out. The Philosophical Society, in which I am chiefly interested, and of which I enclose last year's report, has done much good work in bygone days, but owing to a variety of circumstances it is not at present quite so flourishing as we could wish. However, I am glad to say that at the last Council meeting it was decided to publish a pamphlet containing a list of the specimens in the various branches of Natural History to be found about the neighbourhood, both on the land and in the sea. This will be but a commencement, and will be distributed among the inhabitants and visitors with a request that a notice of any alterations or additions should be sent to the Society for future publication. Thus it is hoped that fresh interest will be awakened.

My own idea is that our failure arises from a multiplicity, not a paucity of institutions, and that their aims are too high. I believe one good institution would be far better than all the separate ones. Thus we have the Literary Institution, subscription twenty-five shillings a year. This is in the old part of the town, and formerly possessed the museum and a good set of meteorological instruments. The only privileges members have are the reading room and a good standard library, which, however, has hardly been added to for some years. Next we come to the Philosophical Society, subscription 10*s*. 6*d*. a year. This certainly tries to do something, for there are papers read on various subjects, and each session concludes with a conversazione. But in my opinion its weak point is that the majority of papers read have no local bearing. I acknowledge that many display great ability, but the chief aim of such a Society should be the collection and description of subjects connected with *local* natural history, botany, climate, archæology, geology, &c., and wider researches should be left for other more suitable societies, or for special occasions now and then. The Mechanics' Institution I believe is getting on pretty well. There is a reading room, with a library, and lectures are delivered on all imaginable subjects.

If these three institutions could unite, instead of being to a certain extent antagonistic to each other, great advantage, I am sure, would accrue to the members and science generally, although none but those who have gone into the question can imagine the difficulties that would have to be overcome before a harmonious union could be effected.

The Science and Art class to which you refer has recently been organised, and is said to be answering very well.

There is, however, a possibility that this state of things will be soon partly altered, for rumours are afloat that our excellent member, Mr. Brassey, has offered to provide a suitable building in which all the local societies will have apartments, but no particulars are yet known.

Hastings, Jan. 28 ALEX. E. MURRAY

P.S.—Since writing the above I remember that I have omitted the Athenæum, but as this is mainly a debating society it has little to do with the advance of science.

OUR ASTRONOMICAL COLUMN

THE TOTAL SOLAR ECLIPSE OF 1876, SEPT. 17–18.—The track of totality in this eclipse is wholly upon the Pacific Ocean, and in such course that only two or three small islands or reefs appear to be situate near the central line. Using the *Nautical Almanac* elements, which are almost identical with those of the American Ephemeris, wherein the moon's place is derived from Peirce's Tables, St. Matthias Island, west of Admiralty Islands off the north-east coast of New Guinea, is traversed by the central track of the shadow, with the sun at an altitude of 5° at 6h. 16m. A.M. on the 18th local time. Thence skirting Ellice Islands it passes between the Fiji's and the Samoan or Navigator group to Savage Island, in 170° west of Greenwich, latitude 19° south, which is apparently the only spot where totality may be witnessed under anything like favourable conditions, and even here the duration of totality is less than one minute. The after course of the central line does not encounter any land.

In the northern of the two large islands of the Fiji group (Vanua Levu) 179° east, a partial eclipse will occur commencing at 7h. 47m. A.M. local time 44° from the sun's north point towards the west for direct image, and ending at 10h. 16m., magnitude 0·86. In the larger island of the Navigator group, Savaii, of the Admiralty Chart, there will also be a partial eclipse, though nearly approaching totality; eclipse begins 8h. 23m. A.M. at 53° from the sun's north point towards the west, and ends at 11h. 2m., magnitude 0·97.

Assuming the north point of Savage Island to be in 169° 48′ W., with 18° 55′ south latitude, a direct calculation gives a total eclipse commencing at 10h. 8m. 6s. A.M. local mean time, and continuing 57 seconds with the sun at an altitude of 58°; the first contact of the moon with the sun's limb at 8h. 48m. A.M., 49° from his north point towards west for direct image, and the end of the eclipse at 11h. 29m.

In New Zealand the eclipse attains a magnitude of about 0·5 at Auckland, greatest phase at 9h. 18m. A.M.; towards the extremity of the southern island about Otago, one-third of the sun's diameter will be obscured about 9h. 12m. local time. A partial eclipse between similar limits will be visible on the east coast of Australia and in Van Diemen's Land.

MINOR PLANETS.—The long period of revolution assigned to No. 153, *Hilda*, by the early calculations has been confirmed by a new determination of the elements by Herr Kühnert, of Vienna, upon more than eight weeks' observations. The orbit is as follows:—

Mean Longitude, 1875, Dec. 19, at Berlin noon ...	34° 58′·7
Longitude of perihelion ...	285° 1′·6
„ „ ascending node ...	228° 20′·5
Inclination to ecliptic ...	7° 50′·9
Excentricity ...	0·16311
Mean diurnal motion ...	451″·91
Semi-axis major ...	3·9504

Hence the period of sidereal revolution is 2,868 days, or 7·85 years.—For No. 158 detected at Berlin on Jan. 4, Dr. Maywald, who has been so long occupied in computations connected with the minor planets, has proposed the name "Koronis."—No. 155, discovered by Palisa at Pola on Nov. 8, has so far been observed only on four nights, and these observations being at intervals which render them unavailable for calculation of elliptical elements, it appears not unlikely that it will be lost, as are already several minor planets similarly circumstanced, unless an effort be made to recover it with the aid of circular elements in the next period of absence of moonlight, and with some one of the larger telescopes; it was not brighter than a star of the twelfth magnitude at discovery, and must now be considerably fainter.—The period of revolution of No. 150 by seven weeks' observations is 1,879½ days.

M. Paul Henry, of the Observatory of Paris, announces his discovery of No. 159 on Jan. 26.

THE SECOND COMET OF 1702.—A complete reduction and discussion of the observations of this comet, taken at Rome by Bianchini and Maraldi, does not afford indications of elliptical motion, as might be surmised to exist from the small inclination of the orbit to the ecliptic and the direct movement. In fact, these observations appear to be by no means precise, and the differences from calculation *inter se* are too irregular to afford any hope of sensibly improving upon the orbit given by Burckhardt. Considering that the differences of right ascension between the comet and comparison stars were taken by means of clocks, and the differences of declination measured by a micrometer scale, the arc value of which was determined by observation of the sun's diameter, rather better places might have been looked for. The following are the errors given by Burckhardt's orbit, as compared with the newly reduced positions in which aberration and parallax have been taken into account:—

1702, April 20	$\Delta\lambda.\cos.\beta$ ...	+ 7′·2	$\Delta\beta$ ...	− 1′·2
„ „ 21	„ ...	− 1·6	„ ...	− 6·1
„ „ 26	„ ...	− 1·4	„ ...	− 1·8
„ „ 27	„ ...	− 3·5	„ ...	+ 2·4
„ May 2	„ ...	+ 9·1	„ ...	− 3·1
„ „ 4	„ ...	− 7·6	„ ...	− 3·6

The comet was at its least distance from the earth on the night of April 19, when it approached our globe within 0·0438 of the earth's mean distance from the sun.

PROF. TYNDALL ON GERMS*

IN further illustration of the dangers incurred in this field of inquiry the author refers to the excellent paper of Dr. Roberts on Biogenesis, in the "Philosophical Transactions" for 1874. Dr. Roberts fills the bulb of an ordinary pipette to about two-thirds of its capacity with the infusion to be examined. In the neck of the pipette he places a plug of dry cotton-wool. He then hermetically seals the neck and dips the bulb into boiling water or hot oil, where he permits it to remain for the requisite time. Here we have no disturbance from ebullition, and no loss by evaporation. The bulb is removed from the hot water and permitted to cool. The sealed end of the neck is then filed off, the cotton-wool alone interposing between the infusion and the atmosphere.

The arrangement is beautiful, but it has one weak point. Cotton-wool free from germs is not to be found, and the plug employed by Dr. Roberts infallibly contained them. In the gentle movement of the air to and fro as the temperature changed, or by any shock, jar, or motion to which the pipette might be subjected, we have certainly a cause sufficient to detach a germ now and then from the cotton-wool which would fall into the infusion and produce its effect. Probably, also, condensation occurred at times in the neck of the pipette; the water of condensation carrying back from the cotton-wool the seeds of life. The fact of fertilisation being so rare as Dr. Roberts found it to be is a proof of the care with which

* On the Optical Deportment of the Atmosphere in reference to the Phenomena of Putrefaction and Infection. Abstract of a paper read before the Royal Society, January 13th, by Prof. Tyndall, F.R.S. (Communicated by the author.) Continued from p. 254.

his experiments were conducted. But he did find cases of fertilisation after prolonged exposure to the boiling temperature; and this caused him to come to the conclusion that under certain rare conditions spontaneous generation may occur. He also found that an alkalised hay-infusion was so difficult to sterilise that it was capable of withstanding the boiling temperature for hours without losing its power of generating life. The most careful experiments have been made with this infusion. Dr. Roberts is certainly correct in assigning to it superior nutritive power. But in the present inquiry five minutes boiling sufficed to completely sterilise the infusion.

Summing up this portion of his inquiry, the author remarks that he will hardly be charged with any desire to limit the power and potency of matter. But holding the notions he does upon this point, it is all the more incumbent on him to affirm that as far as inquiry has hitherto penetrated, life has never been proved to appear independently of antecedent life.

Though the author had no reason to doubt the general diffusion of germs in the atmosphere, he thought it desirable to place the point beyond question. At Down, Mr. Darwin, Mr. Francis Darwin; at High Elms, Sir John Lubbock; at Sherwood, near Tunbridge Wells, Mr. Siemens; at Pembroke Lodge, Richmond Park, Mr. Rollo Russell; at Heathfield Park, Messrs. Hamilton; at Greenwich Hospital, Mr. Hirst; at Kew, Dr. Hooker; and at the Crystal Palace, Mr. Price, kindly took charge of infusions, every one of which became charged with organisms. To obtain more definite insight regarding the diffusion of atmospheric germs, a square wooden tray was pierced with 100 holes, into each of which was dropped a short test-tube. On Oct. 23, thirty of these tubes were filled with an infusion of hay, thirty-five with an infusion of turnip, and thirty-five with an infusion of beef. The tubes, with their infusions, had been previously boiled, ten at a time, in an oil-bath. One hundred circles were marked on paper so as to form a map of the tray, and every day the state of each tube was registered upon the corresponding circle. In the following description the term "cloudy" is used to denote the first stage of turbidity; distinct but not strong. The term "muddy" is used to denote thick turbidity.

One tube of the 100 was first singled out and rendered muddy. It belonged to the beef group, and it was a whole day in advance of all the other tubes. The progress of putrefaction was first registered on Oct. 26; the "map" then taken may be thus described:—

Hay.—Of the thirty specimens exposed one had become "muddy"—the seventh in the middle row reckoning from the side of the tray nearest the stove. Six tubes remained perfectly clear between this muddy one and the stove, proving that differences of warmth may be overridden by other causes. Every one of the other tubes containing the hay infusion showed spots of mould upon the clear liquid.

Turnip.—Four of the thirty-five tubes were very muddy, two of them being in the row next the stove, one four rows distant, and the remaining one seven rows away. Besides these six tubes had become clouded. There was no mould on any of the tubes.

Beef.—One tube of the thirty-five was quite muddy, in the seventh row from the stove. There were three cloudy tubes, while seven of them bore spots of mould.

As a general rule organic infusions exposed to the air during the autumn remained for two days or more perfectly clear. Doubtless from the first germs fell into them, but they required time to be hatched. This period of clearness may be called the "period of latency," and indeed it exactly corresponds with what is understood by this term in medicine. Towards the end of the period of latency, the fall into a state of disease is comparatively sudden; the infusion passing from perfect clearness to cloudiness more or less dense in a few hours.

Thus the tube placed in Mr. Darwin's possession was clear at 8.30 A.M. on Oct. 19, and cloudy at 4.30 P.M. Seven hours, moreover, after the first record of our tray of tubes, a marked change had occurred. It may be thus described:—Instead of one, eight of the tubes containing hay-infusion had fallen into uniform muddiness. Twenty of these had produced Bacterial slime, which had fallen to the bottom, every tube containing the slime being covered by mould. Three tubes only remained clear, but with mould upon their surfaces. The muddy turnip-tubes had increased from four to ten; seven tubes were clouded, while eighteen of them remained clear, with here and there a speck of mould on the surface. Of the beef, six were cloudy and one thickly muddy, while spots of mould had formed on the majority of the remaining tubes. Fifteen hours subsequent to this observation, viz. on the morning of Oct. 27, all the tubes containing hay-infusion were smitten, though in different degrees, some of them being much more turbid than others. Of the turnip-tubes, three only remained unsmitten, and two of these had mould upon their surfaces. Only one of the thirty-five beef-infusions remained intact. A change of occupancy, moreover, had occurred in the tube which first gave way. Its muddiness remained grey for a day and a half, then it changed to bright yellow green, and it maintained this colour to the end. On the 27th every tube of the hundred was smitten, the majority with uniform turbidity; some, however, with mould above and slime below, the intermediate liquid being tolerably clear. The whole process bore a striking resemblance to the propagation of a plague among a population, the attacks being successive and of different degrees of virulence.

From the irregular manner in which the tubes are attacked, we may infer that, as regards *quantity*, the distribution of the germs in the air is not uniform. The singling out, moreover, of one tube of the hundred by the particular *Bacteria* that develop a green pigment, shows that, as regards *quality*, the distribution is not uniform. The same absence of uniformity was manifested in the struggle for existence between the *Bacteria* and the penicillium. In some tubes the former were triumphant; in other tubes of the same infusion the latter was triumphant. It would seem also as if a want of uniformity as regards *vital vigour* prevailed. With the self-same infusion the motions of the *Bacteria* in some tubes were exceedingly languid, while in other tubes the motions resembled a rain of projectiles, being so rapid and violent as to be followed with difficulty by the eye. Reflecting on the whole of this, the author concludes that the germs float through the atmosphere in groups or clouds, with spaces more sparsely filled between them. The touching of a nutritive fluid by a Bacterial cloud would naturally have a different effect from the touching of it by the interspace between two clouds. But as in the case of a mottled sky, the various portions of the landscape are successively visited by shade, so, in the long run, are the various tubes of our tray touched by the Bacterial clouds, the final fertilisation or infection of them all being the consequence. The author connects these results with the experiments of Pasteur on the non-continuity of the cause of so-called spontaneous generation, and with other experiments of his own.*

On the 9th of November a second tray containing one hundred tubes filled with an infusion of mutton was exposed to the air. On the morning of the 11th six of the

* In hospital practice the opening of a wound during the passage of a Bacterial cloud would have an effect very different from the opening of it in the interspace between two clouds. Certain caprices in the behaviour of dressed wounds may possibly be accounted for in this way. Under the heading "Nothing new under the Sun," Prof. Huxley has just sent me the following remarkable extract:—"Uebrigens Kann man sich die in der Atmosphäre schwimmenden Thierchen wie Wolken denken, mit denen ganz leere Luftmassen, ja ganze Tage völlig reinen Luftverhältnisse wechseln." (Ehrenberg, "Infusions Thierchen," 1838, p. 525.) The coincidence of phraseology is surprising, for I knew nothing of Ehrenberg's conception. My "clouds," however, are but small miniatures of his.

ten nearest the stove had given way to putrefaction. Three of the rows most distant from the stove had yielded, while here and there over the tray particular tubes were singled out and smitten by the infection. Of the whole tray of one hundred tubes, twenty-seven were either muddy or cloudy on the 11th. Thus, doubtless, in a contagious atmosphere, are individuals successively struck down. On the 12th all the tubes had given way, but the differences in their contents were extraordinary. All of them contained *Bacteria*, some few, others in swarms. In some tubes they were slow and sickly in their motions, in some apparently dead, while in others they darted about with rampant vigour. These differences are to be referred to changes in the germinal matter, for the same infusion was presented everywhere to the air. Here also we have a picture of what occurs during an epidemic, the difference in number and energy of the Bacterial swarms resembling the varying intensity of the disease. It becomes obvious from these experiments that of two individuals of the same population, exposed to a contagious atmosphere, the one may be severely, the other lightly attacked, though the two individuals may be as identical as regards susceptibility as two samples of one and the same mutton infusion.

The author traces still further the parallelism of these actions with the progress of infectious disease. The *Times* of January 17 contained a remarkable letter on Typhoid Fever signed "M.D.," in which occurs the following remarkable statement:—"In one part of it (Edinburgh), congregated together and inhabited by the lowest of the population, there are, according to the Corporation return for 1874, no less than 14,319 houses or dwellings—many under one roof, on the 'flat' system—in which there are no house connections whatever with the street sewers, and, consequently, no watêr-closets. To this day, therefore, all the excrementitious and other refuse of the inhabitants is collected in pails or pans, and remains in their midst, generally in a partitioned-off corner of the living room, until the next day, when it is taken down to the streets and emptied into the Corporation carts. Drunken and vicious though the population be, herded together like sheep, and with the filth collected and kept for twenty-four hours in their very midst, it is a remarkable fact that typhoid fever and diphtheria are simply unknown in these wretched hovels."

This case has its analogue in the following experiment, which is representative of a class. On Nov. 30 a quantity of animal refuse, embracing beef, fish, rabbit, hare, was placed in two large test-tubes opening into a protecting chamber containing six tubes. On Dec. 13, when the refuse was in a state of noisome putrefaction, infusions of whiting, turnip, beef, and mutton were placed in the other four tubes. They were boiled and abandoned to the action of the foul "sewer gas" emitted by their two putrid companions. On Christmas-day the four infusions were limpid. The end of the pipette was then dipped into one of the putrid tubes, and a quantity of matter comparable in smallness to the pock-lymph held on the point of a lancet was transferred to the turnip. Its clearness was not sensibly affected at the time; but on the 26th it was turbid throughout. On the 27th a speck from the infected turnip was transferred to the whiting; on the 28th disease had taken entire possession of the whiting. To the present hour the beef and mutton tubes remain as limpid as distilled water. Just as in the case of the living men and women in Edinburgh, no amount of fetid gas had the power of propagating the plague, as long as the organisms which constitute the true contagium did not gain access to the infusions.

The universal prevalence of the germinal matter of *Bacteria* in water has been demonstrated with the utmost evidence by the experiments of Dr. Burdon Sanderson. But the germs in water are in a very different condition, as regards readiness for development, from those in air. In water they are thoroughly wetted, and ready, under the proper conditions, to pass rapidly into the finished organism. In air they are more or less desiccated, and require a period of preparation more or less long to bring them up to the starting-point of the water-germs. The rapidity of development in an infusion infected by either a speck of liquid containing *Bacteria* or a drop of water is extraordinary. On Jan. 4 a thread of glass almost as fine as a hair was dipped into a cloudy turnip infusion, and the tip only of the glass fibre was introduced into a large test-tube containing an infusion of red mullet. Twelve hours subsequently the perfectly pellucid liquid was cloudy throughout. A second test-tube containing the same infusion was infected with a single drop of the distilled water furnished by Messrs. Hopkin and Williams; twelve hours also sufficed to cloud the infusion thus treated. Precisely the same experiments were made with herring with the same result. At this season of the year several days' exposure to the air are needed to produce so great an effect. On Dec. 31 a strong turnip-infusion was prepared by digesting thin slices in distilled water at a temperature of 120° F. The infusion was divided between four large test-tubes, in one of which it was left unboiled, in another boiled for five minutes, in the two remaining ones boiled, and after cooling infected with one drop of beef-infusion containing *Bacteria*. In twenty-four hours the unboiled tube and the two infected ones were cloudy, the unboiled tube being the most turbid of the three. The infusion here was peculiarly limpid after digestion; for turnip it was quite exceptional, and no amount of searching with the microscope could reveal in it at first the trace of a living Bacterium; still germs were there which, suitably nourished, passed in a single day into Bacterial swarms without number. Five days have not sufficed to produce an effect approximately equal to this in the boiled tube, which was uninfected but exposed to the common laboratory air.

There cannot, moreover, be a doubt that the germs in the air differ widely among themselves as regards *preparedness* for development. Some are fresh, others old; some are dry, others moist. Infected by such germs the same infusion would require different lengths of time to develop Bacterial life. This remark applies to and explains the different degrees of rapidity with which epidemic disease acts upon different people. In some the hatching-period, if it may be called such, is long, in some short, the differences depending upon the different degrees of preparedness of the contagium.

The author refers with particular satisfaction to the untiring patience, the admirable mechanical skill, the veracity in thought, word, and deed displayed throughout this first section of a large and complicated inquiry by his assistant, Mr. John Cottrell, who was zealously aided by his junior colleague, Mr. Frank Valter.

NOTE. *Jan.* 31.—The notion that the author limited himself to temperatures of 60° and 70° Fahr. is an entire misconception. But more of this anon.

THE OCCURRENCE AND MANUFACTURE OF FLINT SKIN-SCRAPERS FROM NEW JERSEY, U.S.A.

A REMARKABLE feature of the common Indian relics found in Central New Jersey is the very great abundance of "skin-scrapers," as one form of stone implements is everywhere known; and the great care that has evidently been bestowed upon them in the making equally attracts the attention when a series of these implements is examined. That a flint implement used in the preparation of skins for clothing and tent-covering should require as much care in its manufacture as an arrow-point, does not seem probable, and one would naturally expect to find in a scraper simply a comparatively

dull rubbing edge given to a conveniently sized pebble. Such, however, is seldom or never the case, and the class of implements, to which is given the above name, are as marked in their several peculiarities as is any form of stone implement with which we are familiar.

Having remarked the great abundance of these relics, I desire here more particularly to notice several specimens which are of more than ordinary interest. The illustrations 1, 2, 3, and 4, are figures of the very smallest scrapers that I have seen; and what is more remarkable than their small size is the beauty of their finish and their symmetry. They are made of differently coloured jasper, were not found together or in the same neighbourhood, showing that they had different origins, and are not ex-

FIG. 1.

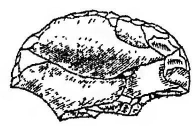

FIG 2.

amples of the fancy of some eccentric chipper of flint implements, such as sometimes occur in masses of broken specimens and flakes that indicate the former site of an arrow-maker's labours.

Not one of these four small scrapers appears to be simply a flake, originally of this shape and subsequently chipped at the scraping edge; but the entire surfaces have undoubtedly been carefully wrought, and show that a small mass of the mineral has been worked to the shape and finish of the specimens, as now found. A quite common form of scraper is the base of an arrow or spear point which has been utilised by subsequently chipping the fractured end, so as to give it a bevelled edge; but the specimens here figured cannot be classed with these, inasmuch as there is nothing suggestive of the arrow-point in their present shape, and unlike them, these four specimens have the under side smooth and slightly concave, a feature not found in the "made over" arrow-heads.

Having seen that so much care was expended on these small scrapers, it is quite certain that these implements were put to some important use, but exactly what, it is difficult to determine. Certainly, in the dressing of the skins of our larger mammals they could be of no use, and of but little even when the skins of the smallest, such as squirrels, were used, which was probably seldom the case, as the larger quadrupeds were as easily obtained. The

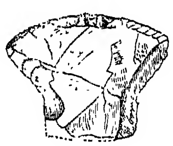

FIG. 3.

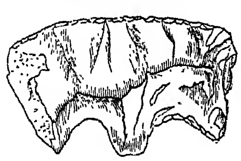

FIG. 4.

skins of birds, if used as ornaments, would not need scraping to make them pliable; and I can only suggest that from the fact of having found traces of bone beads, in graves, made from sections of the long bones of wading birds, I have thought it probable that these small scrapers were used in rounding off the ends of such bone beads; and they might also have been used in the shaping and sharpening of the beautiful bone fish-hooks our aborigines were accustomed to make. Such uses would, of course, make the name "skin-scraper" inappropriate; as I am quite disposed to think it is.

Fig. 5 represents a very perfect specimen of the spoon-shaped scrapers, such as are common in Europe, and by no means rare in the United States. Those found here, as a rule, are not so symmetrical as the specimen figured, and do not have the "bowl" or concave portion of the spoon so decidedly marked. Our New Jersey specimens have this under-surface generally plain, or but slightly concave; and uniform with the stem or handle of the implement. In the specimen figured this is not the case, and the spoon-shape is so pronounced as to suggest that it is a veritable spoon.

Fig. 5 has been chipped from a very pretty agate pebble, such as occur in the gravelly bed of the upper waters of the Delaware River; and it is an interesting

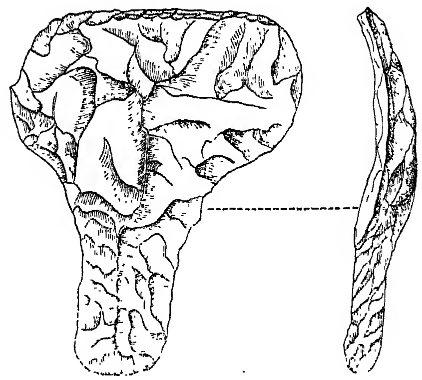

FIG. 5.

fact connected with this class of relics, that the majority are made of jasper, agate, and quartz, minerals the most difficult to shape, and certainly no better adapted to the ordinary uses of these implements—that of scraping the fat from skins.

One word in conclusion. Mr. C. C. Jones, jun., in his work on the "Antiquities of the Southern Indians," writes, under the head of "Scrapers," that "the spoon-shaped scraper of France and Switzerland is more pronounced in form and purpose than any implement of like character it has been my good fortune to find among the relics of the southern tribes."

It is curious that so much variation in the forms of their stone implements should exist in tribes nearly related, and but a few hundred miles apart. Judging from the specimens figured by the author quoted, scrapers were quite simple in their shape and finish; which, as we have seen, is the opposite of what we find in New Jersey, where as great a variety in shapes and sizes occur as exist in the various patterns of arrow-points. *

CHARLES C. ABBOTT

Trenton, New Jersey

THE RECENT BUTTER CASE

AS the case in connection with the Adulteration Act which we discussed in a leading article last week is of considerable importance, both from a scientific and a public point of view, we think it well to put the facts before our readers.

The following summary of the analytical results detailed in Court by the different chemists has been supplied us from a verbatim report of the proceedings before the magistrate at Southwark Police Court.

These results were given after the magistrate's decision had been delivered. They were entirely informal, and took the shape of a discussion, in which everyone appeared to act as his own counsel, and no attempt was made to establish or trace the identity of the samples.

* As authority for applying the term "scraper" to implements similar to Fig. 5, permit me to quote the late Prof. Jeffries Wyman ("Fifth Annual Report of Peabody Museum," 1872, p. 27). He writes, "The term scraper is applied to some of the implements just referred to (a collection from the author), because of their close resemblance to such as bear the same name from the Danish collections belonging to the Museum. They are characterised by having a circular or semi-circular flattened head, with a short projection which might serve as a handle, or for the purpose of attaching one. They differ from the Danish implements chiefly in their much smaller size."

Dr. Muter's analysis—

Water	=	15·00 per cent.
Salt	=	3·96 „ „
Curd	=	2·14 „ „
Foreign fat	=	55·2 „ „
Butter fat	=	23·7 „ „

The fat was thus made up of 30 per cent. of butter fat and 70 per cent. foreign fats. The fat had a melting point below that of butter, and yielded 93·3 per cent. of fatty acids. When examined by the microscope the butter was found to contain fat in a crystalline state, and the so-called curd consisted of vegetable matter, which was described as parenchyma. Finally, the butter was stated to be but slightly rancid.

Dr. Muter said that his standard for genuine butter was 88 per cent. of fatty acids.

Dr. Muter, who appears to have had sufficient of his sample to supply several of his friends, was supported in Court by his assistant Mr. De Konigh, Dr. Dupré, Mr. Wigner, and a microscopist.

Dr. Dupré and Mr. Wigner's Results.—Dr. Dupré found in the fat 94·05 per cent. and Mr. Wigner 94·20 per cent. fixed fatty acids, and the melting-point of the fat 4° C. below that of genuine butter. On a microscopic examination of the butter, both found crystals of fat, which indicated that it had been fused. They also stated that the butter was practically free from rancidity.

Dr. Dupré was of opinion, from the results of his analysis, that there was a doubt whether the sample contained any butter at all; and Mr. Wigner considered that if it contained any butter-fat the quantity must be small, but indeed he thought it was foreign fat simply flavoured with caproic acid. He further stated that his standard for pure butter was 87·5 per cent. fatty acids.

Somerset House Results.—The portion of the sample retained by the inspector, and referred by the magistrate to Somerset House for analysis, weighed about 45 grammes, and it was stated that the experiments performed were not only of an exhaustive character, but were repeated in most instances.

The chemists there found as follows:—

Water	=	9·83 per cent.
Salt	=	3·70 „
Curd	=	0·93 „
Fat	=	85·54 „

The fat gave a melting point of 33·3° C., a density of ·9053 at 100° Fahr., and yielded 88·7 per cent. fatty acids, the latter being seven-tenths above Dr. Muter's standard.

The butter was found to be very rancid, and this rancidity would account for the slight excess of fixed fatty acids, it having been found by actual experiment that butter depreciates by exposure, and that there is a corresponding increase of the fixed fatty acids found in the fat.

On a microscopic examination the butter was found to be free from crystals of fat, and the only foreign substances present were a few particles of impurities consisting of hard wood and cotton thread.

The following are the results of the analysis of the fat of an article corresponding to "butterine," which was referred to in Court as having been examined in exactly a similar way as the sample in dispute:—

Fatty acids, 93·32 per cent., melting-point, 25° C., and density of fat at 100° F. = ·90108.

The processes followed by the different chemists for the analysis of the samples differed but little, but the chemists at Somerset House adopted an additional safeguard against error in saponifying the fats, by taking the density of the fat in the sample at a temperature of 100° F.

The melting-point, the density of the fat, and the quantity of fixed fatty acids were clearly shown to be in complete accord, and these three results are certainly most important in their direct bearing on the accuracy of the analysis.

NATURAL HISTORY OF ST. HELENA

THE following extracts from a letter addressed to Dr. Hooker by Mr. Wollaston, who has been residing for some months in St. Helena for the purpose of investigating the insect fauna, can hardly fail to be interesting to students of geographical distribution:—

"Plantation House, St. Helena, Nov. 22, 1875

"At this season of the year it is extremely difficult to obtain seeds, for the genuine native plants which are still not extinct, in addition to being extremely few in number, nearly all grow in places very difficult of access at a time when the upper ridges are nearly always covered with cloud, and only a certain proportion of them are showing any signs of active life (in the shape of flowers and seeds); but I have been able to collect three out of the four species of cabbage-trees, a *Lobelia*, two or three Wahlenbergias, and (best of all) the extremely rare *Aster* (or *Commidendron*) *Burchellii*. This last is, I think, as nearly extinct as anything still living can be. Mr. Melliss says there is only one plant of it in the island; but in that he is wrong, for we counted two or three, in full blossom, in the same grove of the *Aster gummiferus*, in which he records the existence of his single individual. We have, however, seen it nowhere else, and it is decidedly on its last legs. Even the *A. gummiferus* is excessively rare, and I shall hope to get you seeds of it before we leave the island; as well as of the *Commidendron robustum* (the true 'gum-wood'). . . . The *A. Burchellii* is so rare that I have been drying you a few specimens, feeling that (as it may soon be gone altogether if we cannot persuade the islanders to spare it from their donkey-loads of firewood) you might, perhaps, like some fresh ones. . . .

"The insect flora, although so extremely limited that I have not in nearly even three months collected more in Coleoptera than 150 species, still continues to keep up its character for eccentricity—ringing the changes on some half a dozen types (chiefly Rhyncophorous) to a marvellous extent. We seem indeed never to exhaust them, turning up new species almost every time that we can secure a hard day's work on the *Compositæ* ridge. Having ultimately to work them out, I take scores of specimens, and must have mounted carefully some six or seven thousand already." T. D.

NOTES

THE following are the proposed movements of H.M.S. *Challenger*:—She was to leave Valparaiso on Dec. 10, and arrive at the Falkland Isles on Jan. 10; leave on Feb. 6, arrive at Monte Video Feb. 18; leave Feb. 28, arrive at Tristan d'Acuhna March 20; leave March 21, arrive at Ascension April 7; leave April 14, arrive at St. Vincent May 5; leave May 12, and arrive in England June 12.

THE Senior Wrangler in this year's Cambridge Mathematical Tripos is Mr. Joseph Timmis Ward, of St. John's, son of the late Mr. Henry Ward, of Banbury. He was educated at Rochester Cathedral Grammar School, under the Rev. R. Whiston. Mr. William L. Mollison, of Clare, the Second Wrangler, is a native of Aberdeen, and is the son of Mr. W. Mollison, of that town. He was educated at the Grammar School and University of Aberdeen.

WE would call attention to the advertisement in to-day's NATURE by the Kew Committee, offering to the public greater facilities for the verification of instruments than have hitherto existed at Kew.

WE understand that the eminent ornithologist, Dr. G. Hartlaub, of Bremen, has in preparation a new work on the Birds of Madagascar. This will be a considerable undertaking, as since

the publication of Dr. Hartlaub's last work on this subject ("Ornithologischer Beitrag zur Fauna Madagascars," Bremen, 1861), great additions have been made to our knowledge of the ornithology of this wonderful island by the investigations of Pollen, Van Dam, Grandidier, Crossley, and other naturalists.

DR. O. FINSCH, of Bremen, and Alfred Brehm—both well-known German naturalists—will accompany the scientific expedition to the Obi (Northern Siberia), which is to start in March next.

THE Museum of Bremen, founded by a private society of merchants, and well known to ornithologists of all countries from the rarity of many of the specimens and the excellent manner in which they are mounted, will shortly become the property of the City of Bremen. It is said that Dr. O. Finsch is likely to be appointed its first director under the new *régime*. We may add that no more eligible selection could be made.

NEW ZEALAND papers just to hand report an interesting discovery of moa bones in that colony farther north than any have previously been found. No remains of the extinct bird having been discovered north of the town of Auckland; the moa region was supposed to have lain altogether to the south of that place. The advices now received, however, state that numerous bones, representing the skeletons of fifteen moas, have been found along the beach for many miles north of Whangarei Heads, sixty miles to the north of Auckland. The discoverers were Mr. George Thorne, and Mr. Kirk, the Secretary of the Auckland Institute. With the moa bones were discovered several human skulls and a complete human skeleton in a sitting posture (the position in which it was usual to bury Maoris); also many large pebbles, such as the moa was in the habit of swallowing with its food, a rude stone hatchet, and some chips of obsidian. The spot where the remains were discovered was at one time covered with vegetation, but this having been burned by bush fires the ground had been covered by drifting sand, the disturbance of which by the wind has exposed the bones. The natives in the district had no knowledge whatever of the existence of any of the remains discovered, whose antiquity is believed to be considerable. Further researches in the same locality may possibly be productive of interesting results.

A LETTER from M. Alluard, the director of the Puy de Dôme Observatory, has been published in the *International Bulletin* of Jan. 29, intimating that the establishment is now in full operation. M. Alluard has ascended the mountain for the purpose of taking instruments to the observers on the top. The elevation is about 6,000 feet above the level of the sea. It was on the top of the Puy de Dôme that, in 1647, Perier, the brother-in-law of Pascal, verified the fact, discovered at Paris, that pressure diminishes with the altitude. The first experiments were made by Pascal himself on the top of St. Jacques la Boucherie, whose height is about ninety feet. A statue of Pascal was placed on the basement of the tower about 1862, when occurred the second centenary of his death. The top of the Puy de Dôme is to be connected by a telegraphic wire with the Clermont Academy of Sciences, so that observations may be recorded daily and sent by telegram to every station in correspondence with the International Service.

AT the Court of Common Council last week Sir Charles Reed presented a resolution of the Committee for managing the Gresham College Trusts, of which Committee Sir Charles is a member, and Lord Selborne Chairman. Sir Charles gave a brief history of the institution, which, as our readers may surmise, was a record of decay and misappropriation. Sir Charles's motion, which was agreed to, was that the Gresham Committee (City side) be authorised to put themselves in communication with the Charity Commissioners, with the view of effecting the objects contemplated. In 1867 the Gresham Committee was advised by counsel that the only satisfactory solution of the difficulty would be found in the agreement of the Corporation and the Mercers Company to propound a scheme for the sanction of Parliament. That agreement has now happily been arrived at. We hope that Sir Charles's prediction will be realised, and that the result of the deliberations will be a scheme which will cause the College once more to represent the wishes of the founder in making it, what he originally designed it to be, a college for the furtherance and advancement of learning in London.

INTELLIGENCE received at Lisbon last week announced that Lieut. Cameron was almost completely restored to health. Baron Barth, the well-known German geographer, had arrived at Lisbon *en route* for Angola.

A REPORT by Drs. W. Elgar Buck and G. C. Franklin, on the Epidemic Diarrhœa of 1875 in Leicester, has been presented to the Sanitary Committee of that borough and printed. After a careful analysis of the whole facts, the authors show that Leicester is not an unhealthy town as regards the adult population; that the excessive rate of its infantile mortality, which really regulates the total mortality, is due to a "specific diarrhœa," eminently fatal, which prevails in July, August, and September; that such conditions, as are often assigned as causes of this destroyer of infant life, viz., early age or debility of parents, maternal neglect and debility, non-suckling, and opium-poisoning of infants exist in Leicester, as in other manufacturing towns, but have no appreciable effect in the main question at issue; and that the houses in which the fatal cases occur are not in themselves insanitary as regards size and number of rooms, water supply, ventilation and space, house drainage, and closet accommodation. The disease is not diffused equally among all classes of the community, the wealthy classes being wholly exempt from it as regards fatal results; and it is not the most densely-peopled districts, nor the poorest sections of the community in which the mortality is greatest; but the disease is most prevalent where the soil is water-logged, where sewers are liable to be blocked up, and where the houses have been built on undrained ground made up of refuse from all parts. In those districts of the town where these conditions exist in a less degree, the disease is less prevalent, and where they do not exist, the disease is almost wholly unknown. Drs. Buck and Franklin recommend, for the mitigation of the disease, that the subsoil be efficiently drained of its superfluous water, that a free outfall be found for the sewers, and that clay-pits or other excavations should not be filled up with filthy ash-bin refuse and then built upon. We hope that the authors of this suggestive Report will resume the inquiry next summer with the view of modifying or confirming the results they have arrived at, and of throwing further light on the history of this terrible epidemic, which every year almost assumes the magnitude of a pestilence among the infants of Leicester.

M. DE TOUCHIMBERT reports that in the district round Poitiers, the sowing of the winter cereals has been remarkably and very seriously interfered with, first by the drought which prevailed up to the close of October, and then by continuous rains for the first fortnight in November, followed by severe frosts during the rest of the month. Heavy storms of wind followed each other in succession on Nov. 9, 10, and 11, doing great damage to houses, and uprooting and otherwise destroying trees. Pneumonia and bronchitis have been peculiarly prevalent, owing probably to these violent alternations of drought, great humidity, and low temperature.

M. ALBERT LE BLEU, chief engineer of mines at Rodez, has visited the Paris Observatory to consult regarding the organisation of the Departmental Meteorological Commission, of which

he is president. The Commission proposes to apply the grant received from the Council-general to a thorough examination of the rainfall, the thunderstorms, and particularly the storms of hail in the different valleys of Aveyron. An anemometer is to be erected at the top of the cathedral. In developing the extremely difficult question of the issue of weather forecasts calculated to be practically useful to agriculturists, it is recognised that the essential conditions of success as regards the observers are sound sense, intimate knowledge of the physical features of the district, and shrewdness in interpreting weather signs, such as long residence in the locality alone can give, and that it is also essential to success to carry out a minute and extensive observation of the rainfall, thunderstorms, and storms of hail within and immediately surrounding the district to which the weather-warnings are sent.

MR. JAMES PATON, who for many years has been connected with the Museum of Science and Art, Edinburgh, has been appointed Curator of the Industrial Museum, Glasgow.

THE first general meeting of the Mineralogical Society of Great Britain and Ireland is held to-day at the Scientific Club, Saville Row, at 12 o'clock (noon), when the chair will be taken by Mr. H. C. Sorby, F.R.S. The first ordinary meeting will be held at the same place and time to-morrow, when a paper will be read on the Scottish Rhombohedral Carbonates, by Prof. M. Forster Heddle, M.D.

IT is proposed to establish a Technical College for Glasgow. In so far as the teaching of the textile department is concerned, the accomplishment of the scheme is all but assured.

As the Algerian Government have refused to take observations at eight o'clock in the morning, as in Europe, a Constantine newspaper, *Progrès de l'Est*, proposes to open a public subscription in order to send to France and England daily telegrams making known the state of weather in the colony. These weather telegrams are to be posted in the several hotels of Paris, London, Lyons, Marseilles, and other large cities, where intending tourists are likely to see them.

A SLIGHT earthquake was felt in Constantine, Algeria, at nine o'clock on the morning of Jan. 20. No damage was experienced. The duration was two seconds, and the shock vertical.

THE town of Abancay, in Peru, is reported to have been destroyed by an earthquake between 4 P.M. on the 4th and 9 A.M. on the 5th December. Thirty-seven shocks occurred, several very severe, with loss of life, the extent of which was not known.

BY decree of the French Government, a Chair of Physical Astronomy has been established in the Faculty of Science, Bourdeaux, to be filled by M. Rayet, and at Lyons a Chair of Industrial and Agricultural Chemistry, to be filled by M. Raulin.

TWO academies of medicine have been established by a decree of the President of the French Republic at Nantes and Marseilles.

PROF. TARGIONI has been appointed by the Italian Minister of Agriculture and Commerce Director of an Agrarian Entomological Station at Florence.

IN the *Brighton Observer*, which made its first appearance in its new form on Friday last, is a London letter on the scientific doings of the week. It appears to be the first of a series, in which it is intended to give, in a popular form, an account of the lectures and papers read before the societies which are likely to be of general interest. The idea is, we believe, a novel one, and we hope it will find favour with readers.

THE rockwork in the tanks at the new Westminster Aquarium contains a considerable amount of Portland oolite. We understand that it was purchased from the *débris* of the Colosseum, Regent's Park, as a sandstone, and it appears to have been introduced into salt and fresh tanks alike without investigation as to how far it is suitable. It perhaps may do no harm, but it would be well if anyone who has experience of what its effect will be would communicate his knowledge before any animals are placed in the tanks. There is, in addition, a good supply of Carboniferous limestone used, and in considering the conditions, it must be remembered that the water circulates constantly from tank to tank, so that the carbonate of lime will be just as present to all the inhabitants of the aquarium as to the Lamellibranchs and others it might benefit.

THE last-issued number of the publication of the Eastbourne Natural History Society contains a paper by Mr. Jenner on the Macro-Lepidoptera of East Sussex.

THE additions to the Zoological Society's Gardens during the past week include a Rhesus Monkey (*Macacus erythræus*) from India, presented by Mr. T. O. Davis; a Black-faced Spider Monkey (*Ateles ater*) from Central America, two Green Turtles (*Chelone viridis*) from the West Indies, presented by Captain King; a Grey Ichneumon (*Herpestes griseus*) from India, presented by Mr. H. Churchill; a Common Curlew (*Numenius arquatus*), a Herring Gull (*Larus argentatus*), a Common Gull (*Larus canus*), two Black-headed Gulls (*Larus ridibundus*), European, presented by Mr. Charles Clifton.

THE LOAN EXHIBITION OF SCIENTIFIC APPARATUS

THE following is a list of the members of the Foreign Committees, the appointment of whom has been already notified to the Department of Science and Art:—

BELGIUM.—M. le Général Brialmont, M. Dewalque, M. le Général Liagre, M. Maus, M. Plateau, M. Schwann, M. Stas, M. Van Beneden.

FRANCE.—M. Alexre. Edmond Becquerel, M. Henri Marie Bouley, M. Gabriel Auguste Daubrée, M. Jean Louis Armand de Quatrefages De Breau, M. Jean Baptiste Dumas, M. Hervé Auguste Etienne Albans Faye, M. Edmond Fremy, M. Jules Célestin Jamin, M. Urbain Jean Joseph Le Verrier, Le Général Arthur Jules Morin, M. Eugène Melchior Peligot, M. Henri Edouard Tresca.

GERMANY.—I. *Berlin Committee.*—Dr. A. W. Hofmann, Dr. Beyrich, Dr. du Bois-Reymond, Dr. Dove, Dr. Förster, Dr. Hagen, T. G. Halkse, Dr. Hauchecorne, Dr. Helmholtz, Dr. Kiepert, Dr. G. Kirchhoff, Dr. Kronecker, Dr. C. D. Martius, Von Morozowicz, Dr. Neumayer, Dr. Reuleaux, Dr. Schellbach, Dr. W. Siemens, Dr. Virchow, Dr. C. H. Vogel, Dr. Websky.—II. *Committee representing other Cities and Towns of Germany.*—Dr. Von Babo, Dr. Beetz, Dr. Buff, Dr. Clausius, His Excellency Dr. Von Dechen, Dr. Von Fehling, Dr. Von Feilitzsch, Dr. Graebe, Dr. Von Groddeck, Dr. Heeren, Dr. Hittorf, Dr. Karsten, Kiel; Dr. Karsten, Rostoch; Dr. Knapp, Dr. Knoblauch, Dr. Kölliker, Dr. Kundt, Dr. Launhardt, Dr. Mohl, Dr. Poleck, Dr. Preyer, Dr. Von Quintus-Icilius, Dr. Reusch, Dr. Romberg, Dr. Rosenthal, Dr. Serlo, Dr. C. Von Siemens, His Excellency Dr. Von Steinbeis, Dr. W. Weber, Dr. Wiedemann, Dr. Winkler, Dr. Wöhler, Dr. Wüllner, Dr. Zeuner, Dr. Zetzsche.

ITALY.—Prof. Blaserna, Prof. Cantoni, Prof. Respighi.

THE NETHERLANDS.—Prof. Dr. P. D. Ryke, Prof. Dr. H. G. de Sande Bakhuyzen, Prof. C. H. D. Buys Ballot, Prof. J. Bosscha, Prof. Dr. F. C. Donders, F.R.S., Prof. J. W. Gunning, Prof. Dr. R. A. Mees, Prof. V. S. Van der Willigen, Dr. D. de Loos (Secretary).

SWITZERLAND.—Prof. E. Wartmann (President), Prof. J. Amsler Laffon, Prof. D. Colladon-Ador, Prof. Dr. F. A. Forel, Prof. Dr. E. Hagenbach-Bischoff, Prof. Ad. Hirsch, Prof. Albert Mousson, M. E. Sarasin-Diodati, Prof. L. Soret Colonel Gautier (Secretary.

PROF. NORDENSKJOLD ON THE JENISEI

IN a letter from Prof. Nordenskjöld, of Stockholm, to Mr. Oscar Dickson, Prof. Nordenskjöld gives the following further details of his expedition.

In my preceding letters I narrated the progress of the Novaya Zemlya Jenisei Expedition up to the time when we, after a boat voyage of fifty to sixty Swedish miles, at Saostrowskoj on Aug. 31, fell in with the steamer *Alexander*, in which we afterwards journeyed 150 Swedish miles further up the Jenisei during a whole month to the town of Jeniseisk.

I proceed now to finish the account of my journey, with a short sketch of this steam voyage.

The *Alexander* was neither a passenger nor a cargo steamer, but formed a moveable warehouse propelled by steam, which was commanded not by seamen but by a friendly and affable merchant, who clearly did not much concern himself with the navigation of the vessel, but rather with trade and goods, and was seldom by the crew called "captain" but generally "hosain" (master). The arrangement of the vessel itself corresponded to this state of things. The whole of the fore-saloon was fitted up as a shop with shelves for goods along the walls, the usual desk, &c. The after-saloon was employed as a counting-house, writing and sleeping apartment for the master, and was besides filled to overflowing with wares of various kinds for sale, spirit casks, &c. There was thus no room for passengers, and at the first when we lay-to with the Swedish flag hoisted, our "hosain," Herr Ivan Michailovitsch Jarmenieff's reception of us was by no means specially friendly. He was even indisposed in the beginning to take us along with him. But no sooner had I, with the help of our pilot Teodor and a Swedish-Russian lexicon, succeeded in explaining to him what sort of people we were and what journey we had made, than all was completely changed, and from that moment we had in our "hosain" the most agreeable and obliging host we could desire. In order to make room for us on board, a cabin before the wheel-house, which had been filled with goods, was emptied and arranged for passengers. Its size was by no means great. During the night, for instance, we could only with difficulty lie alongside each other on a bedstead formed of boards, which took up nearly the whole cabin. Our men at first got places wherever they could, in the engine-room, where they were kindly entertained by the engineer. Afterwards we obtained another more roomy cabin, and our men got that which we had in the beginning.

The navigation of the vessel was managed by two mates, of a stately and original appearance, who, clothed in long caftans, each during his watch sat on a chair at the wheel, generally without steering, for the most part smoking a "papiross," and with the most unconcerned expression in the world exchanging jokes with those who were walking below. A man stood constantly in the fore part of the vessel, unceasingly trying the depth of the water with a long pole. In order to avoid the strong current of the deep central stream the course was taken not in the deepest part of the river, but as near the bank as possible, often so near that we could almost jump to land, and that our Nordland boat, which was towed alongside the steamer, was often drawn over land. The *Alexander* besides had in tow first one, afterwards two vessels (lodjor), nearly of the same size as the steamer itself, intended to receive the fish bought during the voyage, which was generally salted and prepared on board. The whole way between Jeniseisk and the sea there is not a single jetty, and on this account both the steamer and the two lodjor towed in addition a number of larger or smaller barges and boats intended for communication with the land. Siberia,* and especially the river territory of Jenisei, possesses rich coal beds, which probably extend under a great part of the Siberian plain, but as yet are not worked, and attract little attention. Like all the other steamers on the Siberian rivers, accordingly the *Alexander* was fired not with coal but with wood of which 180 fathoms, if I remember rightly, went to the voyage up the river. The steamer could carry only a small portion of this quantity, on which account frequent delays were necessary, not only for trading with the inhabitants, but also for taking fuel on board. The feeble engine, besides, notwithstanding that the safety valves were in case of need overloaded with lead weights, was often enough unable to make head with all it had in tow against the current, which at some places was very powerful, and in the attempt to find stream-free water near the banks, the vessel often went too near land and ran aground, notwithstanding the continual "ladno" cry of the pilot with the pole posted in the forepart of the steamer. We went, therefore, so slowly, that it was only after the lapse of a whole month that we reached the destination of the steamer, the town Jeniseisk, situated about 150 Swedish miles from Dudino.

In such circumstances most passengers by a steamer would be impatient and in bad humour. To us, on the contrary, the delay was welcome; inasmuch as we had thus an opportunity of extending our examination of the flora and fauna of the territory of the Jenisei even beyond the 60th degree of latitude. It is easy to see that a portion of these researches will also have a practical interest; for instance, the examination which Dr. Lundström has made of the flora of North Jenisei.

Our knowledge of it has heretofore been grounded chiefly on observations made by men of science (Middendorff, Schmitt, &c.) who have visited these regions for other purposes, and only in passing have had opportunities of turning attention to the flora. Dr. Lundström's main object, on the contrary, was exclusively botanical (he had before made himself well acquainted with the Arctic plant world by botanical journeys in Lapland and his native Nordland), and as he came during the voyage up the river from the northerly regions, poor in species, to the southerly, richer in species, it was easier for him than for one who travelled in an opposite direction to give the northern limit of a number of species of general occurrence common to Siberia and Scandinavia. Abundance of botanical and climatological material has been collected in this way, which naturally is not yet worked up, but it is easy to see what new light a comparison of the spreading of plants towards the north in our long-cultivated land and the desolate plains of Siberia will shed on the possibility of cultivating the latter country. Already I may be permitted here to mention that in opposition to what would have appeared probable beforehand the northern limit of many plants in Siberia *is situated farther towards the north than in Sweden.* To a certain extent this may perhaps depend on the seed being carried by the great river from more southerly southerly regions, but it also appears that the severe winter of Siberia has by no means any specially injurious influence on the vegetation of the summer.

Immediately after we came on board the steamer weighed anchor and steamed to the church village, Dudino, situated some miles up the river, where its tributary, the Dudinka, falls into it. The village consists of some few houses inhabited by an influential merchant, Sotnikoff, two priests, a "smotritel" (magistrate), a pair of exiles, and some workmen and natives. Sotnikoff carries on an extensive and profitable trade with the natives in the whole of the surrounding district, exchanging grain, cloth, tea, sugar, iron wares, gunpowder, lead, brandy, &c., for furs, fish, mammoth-teeth, &c., which last he sends with the steamer, first up the Jenisei, and afterwards by different methods of communication on to China, Moscow, Petersburg, &c. In his account of his well-known expedition for disinterring a mammoth found near the mouth of the Jenisei, the Petersburg academician Schmitt praises Sotnikoff much for the unselfish and energetic way in which the expedition was assisted by him. To us too was this plain unpretentious merchant specially hospitable and friendly, and it is incumbent on me to mention that we also met with the same reception from all the other notabilities of the place. The friendly clergyman, who was much interested in our journey, even performed a short thanksgiving service for the successful issue of the expedition on board the steamer and declined to accept any special honorarium on this account.

As in the more northerly situated "simovies," the houses in all the villages situated on the Jenisei were built of logs in much the same style as those of the well-to-do peasants in Russia, pretty close together, with richly decorated gables to the street or road of the village. The interior of the houses was, if we except the innumerable cockroaches found everywhere, very clean, and the walls were adorned with numerous, if not very artistically finished photographs and engravings for the most part of the Russian imperial family, remarkable Russian notabilities, generally in general's uniform, scenes from Russian history, &c. Richly ornamented consecrated pictures were always placed in a corner, and before these were always suspended some oil lamps or small wax lights, which were lighted on holydays. Sometimes the floor, at least in the principal room, was besides covered with

* As an instance, may be mentioned some exceedingly rich coal seams, which crop out on the eastern bank of the Jenisei, a little to the south of the town Krasnojarsk, just in the neighbourhood of the place where the "Pacific Railway" of Siberia will probably some day go forward. When I visited the place one of the coal seams was on fire. Nearer the mouth of the Jenisei, too, coal seams of considerable extent occur, for instance, at the bank of a tributary of the Jenisei, not far from Dudino.

mats of furs. The bed consisted of a couch near the roof, so extensive that it occupied a third or a half of the room, and so far from the floor that a man could go under it upright. Food was prepared in large baking ovens, which were daily fired for this purpose, and warmed the hut at the same time. New bread was to be had every day; and even for the poor a large brass tea urn was a necessary household article. We were always sure of meeting with a hearty and friendly reception wherever we stepped over the threshold, and if we stayed a short time we had generally to drink a glass of tea with our hosts whatever time of the day it might be. The dress everywhere somewhat resembled the common Russian; for the better classes for instance wide velvet trousers stuck into the boots, a shirt grandly embroidered with silver, and a wide caftan often trimmed with fur; for the poor, in case he was not too ragged, the same cut, but inferior, dirty, and torn material. During the winter, however, the Samoyede fur dress is worn out of doors both by high and low, by Russian and native, by settled and nomad.

For the present there were in these regions only very few persons who had been banished hither for political reasons, but on the contrary many exiled criminals, and among them also some few Finns, and even a Swede, or at least one who according to his own statement in broken Swedish had formerly served in the King's body-guard in Stockholm. Security for person and property was in all cases complete, and it was remarkable that there was no true difference of caste that could be observed between the Russian-Siberian natives and those who had been banished to those regions for crimes. Little interest even appeared to be taken in knowing the crimes which had caused the banishment. An inquiry on this point was generally met by the sufficiently elastic reply "for bad conduct."

I mentioned above that mammoth teeth here form an important article of commerce. They are also belived to occur in large quantity on the tundra, though the difficulty of communications often renders their removal impossible. Although this is the mammoth region proper, the larger parts of the skeleton are believed to be very rare, and still more mammoth with flesh, hide and hair still remaining. It was, for instance, on the peninsula between Obi and Jenisei, that the great mammoth find by Trofimoff occurred, and in the neighbourhood of the same place was found the mammoth which gave occasion to Schmitt's expedition. It is probable, besides, that the nomad native has the same indisposition to acquaint an official with a large mammoth find as the peasants at home had in former times, and in certain regions still have to give information about a supposed vein of ore.

On Sept. 4 the *Alexander* weighed anchor, and steamed southwards during splendid weather.

The landscape now began by degrees to change its character completely. In fact, on most maps the limit of wood is drawn along the considerable bend which the river Jenisei makes immediately west or north-west of Dudino, and indeed here for the first time numerous pine trees are met with, but seldom more than 20 feet high. These cover the heights with a sparse and by no means attractive vegetation, completely destitute of the beautiful effect which distinguishes the willow and alder bushes farther north. Already some few miles south of Dudino, however, the pine forest became tall, though here we are still north of the Arctic circle. It is here that the forest proper commences—the largest forest of the globe—stretching with little interruption across the whole of Siberia, in one direction, from Ural to the Sea of Ochotsk, and in the other, south of the 58th or 59th degree of latitude, and north of the Arctic circle, at some places, for instance at the rivers Chatanga and Lena, beyond it on to the neighbourhood of 72° N. lat., that is to say, to the mouths of Chatanga and Lena, ten Swedish miles north of North Cape.

During our boat and steam voyage up the Jenisei we had heretofore only landed either upon the eastern bank of the river, which was always high, or on some of the numerous islands which at some places occur in the river, which widens out nearly to a lake. On Sept. 7 we had, for the first time, an opportunity of landing on the western bank of the river, which, like the western bank of most of the rivers flowing from the south to the north, consists of low tracts of land which are inundated in spring. This meadow land was now covered partly with an extraordinarily luxuriant carpet of grass, which of course was untouched by the scythe, partly with an exceedingly peculiar bush vegetation of equal height, in which we found a number of herbs known among us in Sweden, but here six to eight feet high. Compact thickets of a beautiful straight-stemmed willow frequently alternated with even grass turf of a lively green with small streams, tributaries of the Jenisei, in a way which gave the impression of the most beautiful park, carefully kept and watered, and kept clear of withered branches and grass. On the eastern side, on the contrary, the ancient forest proper commenced close to the river bank. Here nature had quite a different stamp of grandeur and gloom. The forest consisted principally of pines, which, even north of the Arctic Circle, were often of the most colossal dimensions, but in such cases many times grey and shortened to half their height by age. Between these the ground was so covered with fallen stems, with branches nearly fresh, half decayed or converted into a mass of wood mould, which was kept together merely by the bark, that one could force his way only with difficulty and with danger of breaking his legs in the thicket. The fallen stems were besides completely covered, many times even concealed by an uncommonly luxuriant moss vegetation; the tree lichens, on the contrary, occur here only sparingly, in consequence of which the spruce firs were devoid of the shaggy clothing common with us, and the bark on the birches which glanced out here and there among the spruce firs was distinguished by an uncommonly blinding whiteness. When one made his way into this monotonous wood a little distance from the river, it was necessary to be well acquainted with the points of the compass; a mistake in this respect had carried us in a direction in which at a distance of a hundred, perhaps two hundred (Swedish), miles, there was no probability of meeting with an inhabited place. In speaking of the vegetation in these regions it may be mentioned that in the northern forest along the river bank there was abundance of wild red and black currants exceedingly well tasted, and of dimensions surpassing even the largest varieties of cultivated currants I have had an opportunity of seeing.

Since we left Jewremow-Kamen, near the mouth of the Jenisei, we had not seen any solid rock at the river banks, but on the 8th we saw solid rocks on the eastern bank. We made here, as at a number of the other places at which we landed, a rich collection of land molluscs. By means of these collections, which have been already handed over to our skilful molluscologist, Dr. C. A. Westerlund, at Ronneby, to be examined, the known mollusc-fauna of North Siberia will be greatly increased, and many erroneous views hitherto prevalent regarding the geographical distribution of this interesting group of animals will be rectified. This holds good also of various land and freshwater invertebrates, of which considerable collections were made, which have already been distributed to specialists for examination.

After having remained for a longer or shorter time at about ten different "simovies" or fishing-stations, we came on Sept. 12 to a "simovie," Silivauskoi, exclusively inhabited by Skoptists. The orthodox Russian Church is, as is well known, tolerant towards men of foreign faiths, Lutherans, Catholics, Jews, Mohammedans, Buddhists, &c., but, on the contrary, in full accordance with what took place in former times within the Protestant world, visits sectaries within its own bosom with temporal punishments in this world and threatens them with eternal in another. Especially in former times have a number of sectaries been sent to Siberia, and there are accordingly peculiar colonies in a very prosperous state to be met with occasionally, exclusively inhabited by a certain sect. Such is the Skopt colony at Silivauskoi, of which it may be remarked that the nature of the religious delusion here excuses the stringency of the law or the administration. For, on the ground of a text in the Gospel of Matthew, interpreted in a peculiar way, all Skoptists subject themselves to a self-mutilation, in consequence of which the sect can exist only through new proselytes, and remarkably enough, these madmen, in fact, notwithstanding, or perhaps just on account of, all persecution, still find successors. A number of Skoptists are Ingrians (Finns from Ingermanland), on which account I could converse with them without difficulty. They related that they had "for righteousness' sake" been torn from their homes, imprisoned, flogged, and sent to Siberia. Here they had by industry and perseverance succeeded in attaining for themselves a certain competence, were hospitable and friendly, and bore with resignation their hard lot, assured that in another life they would reap a rich reward for their self-denial, suffering, and misfortunes here below. They did not kill any warm-blooded animal, "for it was a sin to kill what the Lord had created," which did not prevent them from catching and eating fish, nor from selling to us, who in any case were doomed to perdition, for 18 roubles a beautiful and fat ox, on condition that our own people should slaughter it. Their indisposition to use some animal foods had besides had the good result that their

attention was turned to the cultivation of the soil. Round the huts, accordingly, were patches of land in potatoes, turnips, and cabbage, which at least this year yielded abundant crops, though the colony is situated in the latitude of Avasaxa, that is to say, under the Arctic circle.

Later in the day we came to the Monastery of Troit, in former times renowned and rich, now inhabited only by a single monk, viz., the prior himself. He was a worthy old man, who gave us a hospitable and friendly reception. The apartment for the reception of guests was adorned with a number of portraits of Siberian bishops. There was besides a portrait of a Russian Czar in powdered hair and military uniform, with blue great cross riband. It was a portrait of Czar Paul, but through some exchange the Skoptists had taken it into their heads that the portrait represented their holy prophet, Czar Peter III., whose history they had completely altered in accordance with their idealised conception of the world. An educated man, who belonged to this sect, and on this account had been banished to North Jenisei, informed me accordingly in all seriousness that Czar Peter III. was not murdered, but was knouted and sent to Siberia, &c., all on account of his holiness—as so it happens now that in consequence of all this the portrait of Czar Paul in the Troit Monastery is a sacred picture to which worship is offered. A. E. NORDENSKJOLD

(*To be continued.*)

SCIENTIFIC SERIALS

THE *Journal of the Chemical Society* for December 1875 contains the following papers communicated to the Society:—On the agricultural chemistry of the tea-plantations of India, by J. Campbell-Brown, D.Sc. This lengthy paper contains analyses of the young and old leaves of good plants and of stunted and blighted plants of different varieties, analyses of the wood of good and stunted tea-plants of different varieties, analyses of tea-seed, of the soils of tea-plantations, and of tea from manured and unmanured plants. The author discusses also the analytical results.—On certain new reactions of tungsten, by Prof. J. W. Mallett, of the University of Virginia. The author has found, contrary to the statements in text-books, that the precipitate produced by hydrochloric acid in a solution of an alkaline tungstate is soluble in an excess of the concentrated acid. By adding fragments of metallic zinc to the above-named acid solution, various colours are produced, the most noteworthy being a brilliant magenta. Potassium sulphocyanate and metallic zinc added to the acid solution produce a rich green colour, but when the sulphocyanate is added first to the alkaline tungstate solution, then a considerable quantity of water, then hydrochloric acid, and finally zinc, a fine amethyst colour is produced. The blue colour well known as characteristic of one of the lower oxides of tungsten may be best brought out by the use of hyposulphurous acid (H_2SO_2) as the reducing agent.—The remainder of the journal contains the usual collection of abstracts.

American Journal of Science and Arts, Dec. 1875.—This number commences with a paper of careful observations by Prof. Dana on five of the river valleys of Southern New England, with a view to ascertaining the depression of that region during the melting of the glacier. This he estimates at about 15 feet. He considers that the terraces in the Housatonic, Connecticut, and Thames, which are now so high above the river's surface, were not wholly, or mostly formed when the land was at a much lower level then now, but they were formed when the rivers were at a greatly higher level than now, owing chiefly to the glacial flood. Thus we may have high and numerous terraces along valleys, and yet none be due to an elevation of the land. The height of the streams during the flood above high tide level is estimated in one case at as much as 237 feet (from which the 15 feet depression would be deducted). The amount of depression increased from the sound northwards at about one foot and a half per mile, since Dawson has shown that the height of the beaches at Montreal indicate a depression there of 500 feet. The waters from the melting glacier must have brought down the streams in vast volume to have piled to so great heights before outlets so wide and deep.—Prof. Storer, of Harvard, gives some observations which show (after Schönbein) that ammonia is a constant contaminant of sulphuric acid, and further, that it is a more frequent impurity in chemical substances (prepared with aid of sulphuric acid) than has been supposed.—An abstract is given of a memoir by Prof. Suess of Vienna on the origin of the Alps.—Mr. Andrews describes some new and interesting coal-plants from Perry County, Ohio, and Dr. Becker calls attention to a new feature in the "Comstock Lode" in Nevada.—In a letter from Dr. Gould, of Cordoba Observatory, the writer states that his zone observations, begun in 1872, are now completed; and the entire region from 23° to 80° of south declination has been carefully scrutinised. The 10° round the pole have been examined by Gillis at Santiago and Stone at Cape of Good Hope, and Gould's northern limit overlaps Argelander's southern zone by eight degrees (as Argeländer had requested).

Supplementary December Number.—Mr. Langley here contributes a paper on the solar atmosphere, being introductory to an account of researches made at the Alleghany Observatory. The estimates of the absorptive power of this atmosphere, based on photometric comparison of the centre and edge of the sun, have been widely discrepant; thus Arago thought the light of the centre must be diminished 2·4 per cent. to equal that of the edge; Liais's estimate is 10 and Secchi's 78 per cent. Mr. Langley here describes a new method of measurement free from some of the objections to previous ones; and he thinks the estimates of Secchi (who used La Place's formula) are certainly in excess of the truth. Not much more or less than one half (he considers) of the whole so-called "luminous heat rays" are absorbed, turned back, or converted into work, in the sun's atmosphere. The total thermal absorption is somewhat less. The method is also applicable to sun-spots, &c., and Mr. Langley finds the absolute light of the "nuclei" in spots at least *five thousand times* that of the full moon.—In a supplemental paper on Southern New England during the melting of the great glacier, Prof. Dana discusses the overflows of the flooded Connecticut, which he concludes was at that time a great stream 150 feet deep and fifteen miles wide.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, Jan 6.—On the length of the Spark from a Battery of 600, 1,200, 1,800, and 2400 rod-Chloride of Silver, and some Phenomena attending the Discharge of 5,640 Cells. By Warren De La Rue, D.C.L., F.R.S., and Hugo W. Muller, F.R.S.

On the 24th February, 1875,* we had the honour of communicating to the Society, in conjunction with our friend Mr. Spottiswoode, an account of some experiments to ascertain the cause of stratification in electrical discharges *in vacuo*. These experiments were made with a battery of 1,080 cells of powder-chloride of silver, which was described; we have now in action 3,240 such cells, and have recently completed 2,400 rod-chloride of silver cells,† making our total force 5,640 cells in action. To these will be shortly added another unit of 1,080 cells powder-chloride, and two other units of 1,200 rod-chloride, making a total of 9,120 cells.

We have more recently made a verbal communication to the Society of Telegraph Engineers, and also in October last a written one to the Académie des Sciences of Paris‡, wherein we have stated that the length of the spark in air appears to be in the direct ratio of the square of the number of cells.

Having completed the 2,400 cells, and charged them up in a single day, they were exactly in the same condition as to electromotive force and internal resistance, consequently they afforded the means of testing the truth of the law of the length of spark in a manner more efficacious than had hitherto obtained, the more especially as by the use of paraffin corks and other precautions we had obtained an excellent insulation.

Our assistant, Mr. Fram, has constructed a discharger which permits of the accurate measurement of the distance of the terminals to read to $\frac{1}{1000}$ of an inch, and by estimation to the tenth of that quantity. The nut, through which the screw ($\frac{1}{50}$ of an inch), carrying one of the terminals, works, is divided into two parts, which are separated by a spiral pressure-spring, so as to prevent shake. In making measurements the terminals are separated to a greater quantity than the anticipated striking-distance, and gradually approached until the spark passes; the discharger is then detached from the battery, and after reading the scale, connected up with a separate battery of 10 cells, with a detector-galvanometer in circuit. The terminals are again approached until the motion of the galvanometer indicates contact between

* Proc. Roy. Soc., No. 160, 1875.
† Proc. Roy. Soc., No. 160, 1875, p. 357.
‡ "Comptus Rendus," No. 16, p. 686; No. 17, p. 746, 1875.

them; the scale is again read, and the length of spark obtained by the difference between the first and second reading.

Rod-chloride,	600 cells had a striking-distance of			0·0033 in.
,,	1200	,,	,,	0·0130
,,	1800	,,	,,	0·0345
,,	2400	,,	,,	0·0535

Taking as the unit 600 cells, the spark of which was 0·0033, the length of spark of 1,200, 1,800, 2,400 would, according to theory, be that number multiplied by the squre of 2. 3, 4 respectively.

600 cells,	striking-distance	....	0·0033 in.
1200	,,	0·0033 × 4....	0·0132
1800	,,	0·0033 × 9....	0·0297
2400	,,	0·0033 × 16....	0·0528

which numbers agree nearly with those obtained by experiment.

The length of the spark is much influenced by the shape of the terminals, those which we frequently employ consist of a point as one terminal and a plane for the other; hitherto we have used copper terminals, making the point and the plane alternately positive and negative by means of a double-key discharger, or by a rapidly-revolving commutator reversing up to 352 times in a second. One terminal in the above determinations consisted of a point of 30°, and the other of a slightly convex surface 0·46 inch in diameter.

While making these measurements, we noticed in a nearly dark room that when the point was negative a glow, in form like a paraboloid, was seen surrounding it long before the spark passed, and its appearance afforded by its increasing brilliancy useful information to guide us as to the more cautious approach of the terminals; gradually the sugar-loaf-like glow extended to the positive terminal. With 1,800 cells the glow was seen when the terminals were 0·0545 inch apart, the spark passing at 0·0345 inch; with 2,400 cells the glow began at a distance of 0·0865 inch, the spark passing at 0·0535 inch. Moreover, it was noticed that the disc (positive) became covered all over with a peach-like bloom, which became stronger in the centre as the terminals were made to approach each other, giving rise to Newton's iridescent rings.

In order to study more readily the phenomena accompanying the glow preceding the spark, the whole series of 5,640 cells was used, the terminals being a point as before of 30°, and sometimes a flat disc 1·1 inch in diameter, or a slightly convex one of 0·8 inch in diameter for the other. In all cases a peach-like bloom deposited on the disc, which was connected with the silver (positive) terminal; and when the flat disc was used the deposit was notably greater at the periphery and the centre than in other portions of it. With this number of cells, with the flat disc the glow occurred at 1·073 in., the spark at 0·139 in. With the slightly convex disc occurred at 1·124 in., the spark at 0·140 in.*

To ascertain whether a current really passed when the glow appeared, various vacuum-tubes were interposed in circuit between the battery and one of the terminals; in all cases they were illuminated even before a glow was perceptible on the negative pole; their interposition, as was to be expected, shortened the spark and diminished the distance at which the glow was perceptible. For example, with a hydrogen tube, having a capillary portion between two larger tubes, such as is used for spectrum experiments, and offering a resistance of 190,000 ohms, the glow occurred at 0·939 inch, the spark at 0·092 inch.

A tube of 31 inches between the terminals, and offering a resistance of 350,000 ohms, was brilliantly illuminated when interposed between one terminal and the battery; when the terminals were separated the extreme range of the discharge was 1·2 inch, and before any glow was visible at the negative electrode. How much further between the electrodes it will be possible to obtain a current has yet to be determined with a larger discharger now in course of construction.†

I have alluded to the resistance offered by vacuum-tubes. At first I experienced considerable difficulty in measuring it. For example, when in a Wheatstone's bridge the resistance of the tube was balanced by inserted resistances, the galvanometer could only for a short time be brought to rest, and it was then found that the cause of this was that the tubes rapidly increased in resistance as the current passed. After a time, however, they recovered their original resistance, sometimes rapidly, sometimes only after the lapse of days. The resistances were found not to be dependent on the length of tube, but to a great extent on their bore, capillary tubes offering a considerable resistance. Ultimately it was found that it was better to discard the indications of the galvanometer, and to rely solely on the appearance of a luminosity in the tubes placed on one side of Wheatstone's bridge as soon as the insertion of a balancing resistance was made in the other.

Later on we hope to have the honour of sending to the Society a more detailed statement of our experiments in support of those now quoted, and in confirmation of our former paper on the cause of stratification in elec·ric discharges *in vacuo*.

In conclusion we venture to draw attention to the following consequences of the law of the length of spark being dependent on the ratio of the square of the number of cells of a voltaic battery, in the event of its being confirmed by experiment. Taking as a basis the spark with 600 cells of the rod-chloride of silver battery = 0·0033 inch, a unit of 1000 such cells would give a spark of $\frac{0033 \times 1000^2}{600^2}$ = 0·009166 inch,

one hundred units (100,000) a spark of 91·66 inches,

a thousand units (1,000,000) ,, 91·66 ,, = 764 feet nearly,

whereas a single cell would have a striking-distance of $\frac{1}{109090909}$ of an inch only. As far as our own experiments have gone the law has been confirmed; and although a million cells will probably never be made, a hundred thousand come within the range of experimental possibility.

Geological Society, Jan. 19.—John Evans, president, in the chair.—James Buckingham Bevington, William P. Blake, James Gordon Brickenden, Edward George Dyke, Henry Hamilton Gunn, William Jerome Harrison, and R. G. Warton, were elected Fellows of the Society.—On some unicellular algæ parasitic within Silurian and Tertiary corals, with a notice of their presence in *Calceola sandalina* and other fossils, by Prof. P. Martin Duncan, F.R.S. After noticing the works of Quekett, Rose, Wedl, and Kölliker, which refer to the existence of minute parasitic borings in recent corals, recent shells, and a few fossil mollusca, the author describes the appearance presented by a great system of branching canals of about 0·003 millim. in diameter, in a Thamnastræan from the Lower Cainozoic of Tasmania. He then proceeds to examine the corresponding tubes in *Goniophyllum pyramidale* from the Upper Silurian formation. In sections of that coral one set of tubes runs far into the hard structure; these are straight, cylindrical, and contain the remains of vegetable matter. Neither these tubes, nor any others of the same parasite, have a proper wall: they are simply excavations, the filiform alga replacing the organic and calcareous matter abstracted. In some places the dark carbonaceous matter is absent, and the lumen of the tube is distinguishable by the ready passage of transmitted light. Other tubes run parallel to the wall, and enter by openings not larger than their common calibre. But there are others which have a larger diameter, and in which the cytioplasm appears to have collected in masses resembling conidia; and where fossilisation has destroyed much of the continuity of a tube a series of dark and more or less spherical bodies may be seen. In some places, especially in the spaces between the minute curved dissepiments and tabulæ, hosts of globular spores, with or without tubes emanating from them, may be seen. In *Calceola sandalina* corresponding structures exist sometimes, and the method of entry of the parasite can be examined. The author gave two instances, one of which was seen in section. A decided flask-shaped cavity existed in the wall of the shell, opening outwards and rounded and closed inwards. It was crowded with globular spores (oospores), and these, where near the sides, had penetrated the hard shell, and thus gave a rugged and hairy appearance to the outline of the flask-shaped cavity. After noticing minute structures in a brachiopod included in a Silurian coral, and in a Lower Silurian foraminifer, the author asserted, from the results of his late researches upon the algæ parasitic in corals out of his own aquarium, that the fossil and recent forms are analogous in shape, size, and distribution. He considers that the old parasite resembles *Saprolegnia ferox* in its habit; and as he considers that *Empusina*, *Saprolegnia*, and *Achlya*—members of the Protista—are the same organisms, living under different physical conditions, he names the old form *Palæachlya penetrans*; and he believes that it entered the wall by the spores fixing on to the organic matter, and growing by its assimilation, and that car-

* Postscript, Jan. 7.—At the suggestion of Prof. Stokes, who saw the experiment repeated, the point was made positive, when a longer spark was obtained, namely, 0·154 inch and 0·164 inch.

† Postscript, Jan. 8th.—A current was obtained with the negative point distant 5·¼ inches from a positive plate 6 inches in diameter.

bonic anhydride was evolved. He considers that this acid, assisted by the force of growth and the movement of the cytioplasm, are sufficient to account for the presence of the tubes. Finally, the author draws attention to the probable similarity of external conditions in the Silurian and present times, and to the wonderful persistence of form of this low member of the Protista.—How Anglesey became an Island, by Prof. A. C. Ramsay, F.R.S. The author described and illustrated by sections drawn to scale the contours of the island of Anglesey and the adjacent parts of Carnarvonshire, and noticed that the whole island may be regarded as a gritty undulating plain, the higher parts of which attain an average elevation of from 200 to 300 feet above the sea-level. Similar conditions are presented by the country for some miles on the other side of the straits, and in both the general trend of the valleys is north-east and south-west. The rock surfaces, when bare, show glacial striæ running generally in a direction 30° to 40° west of south. The author indicated that the great upheavals of the crust of the earth forming mountains took place long before the commencement of the Glacial epoch, and that ordinary agents of denudation had ample time for the formation in mountain regions of deep valleys, down which, during the Glacial epoch, glaciers would take their course. He noticed the evidence of this local glaciation furnished by the striation of the Welsh mountains, from which he inferred that these mountains as a whole were not overridden by a great ice-sheet coming from the north, and he described the course of the glaciers flowing from the north-west slopes of Snowdonia as being in the directions west, north-west, and north. These glaciers, however, did not reach the region now occupied by the Menai Straits, but spread out in broad fans on the north-western slopes of the hills now overlooking the Straits, a fact indicated by the directions of the glacial striæ in these parts. Anglesey, therefore, was not glaciated by ice-masses coming from Snowdonia; and as the striations on that island point directly towards the mountains of Cumberland, the author inferred that these markings were produced by a great ice-flow coming from that region, reinforced probably by ice-streams from the north of Scotland, and which were large and powerful enough to prevent the glaciers of Llanberis and Nantffrancon from encroaching on the territory of Anglesey. The author described the rocks bordering the Straits as consisting of nearly horizontal Carboniferous strata, which, from appearances, must once have filled the whole of the region now occupied by the Straits. He considered that the softer shaly, sandy, and marly beds, remains of some of which are still to be seen on the coast, were swept away by the action of the great glacier coming from the north-east, forming a valley now occupied by the sea; and in support of this view he cited the valley of Malldraeth Marsh, running across Anglesey, parallel to that of the Menai Straits, about four miles to the north-west, which a very slight change in conditions would convert into a fjord, differing from the Straits only in being closed at the north-east end.

Meteorological Society, Jan. 19.—Dr. Mann, president, in the chair.—The report of the Council showed that a large amount of work had been done, and that the number of Fellows had greatly increased. The first-class observing stations, which were organised in 1874, have been in regular working order during the past year, their number has been increased, and several have been reinspected. A very interesting account of all that has been done in organising the stations, with the conditions to be fulfilled by the observers in respect to instruments and exposure, the mode of inspecting, and a concise description of each station, with a ground plan on an uniform scale, has been prepared by Mr. Symons. An arrangement has been entered into with the Meteorological Office by which the Society has agreed to furnish, for a consideration, copies of observations from a definite number of stations. Various instructions for observers, prepared by the Station Committee and the Assistant-Secretary, are also given. The joint Committee of Delegates from this and other Societies, appointed to draft complete instructions for the observation and registration of natural periodical phenomena, have finished their labours and sent in their report. A code of rules entitled "Instructions for the Observation of Phenological Phenomena" has been prepared and published. The Rev. T. A. Preston has discussed the first year's observations, and his report is given in full. The Council have taken up the solar radiation observations commenced by the Rev. F. W. Stow, but they intend to compare the readings of the black bulb thermometer *in vacuo* with a bright bulb thermometer also *in vacuo*, both mounted alike, instead of the maximum thermometer in the shade. The Council have also appointed a Permanent Lightning Rod Committee to investigate and record accidents from lightning, to inquire into the principles involved in the protection of buildings, to diffuse exact information regarding the best form and arrangement for lightning conductors, and to consider all phenomena of atmospheric electricity. The balance-sheets show that the Society is in a very satisfactory condition.—The President then delivered his address. In alluding to the establishment of a carefully planned series of observing stations by the Society he illustrated at some length the absolute necessity of following out the inductive method of research in meteorology, and supported his argument by a reference to the history of all the leading branches of physical investigation, in which the prophetic insight of inspired minds had invariably had to be elaborated and perfected by the patient labour of subsequent observation and experiment. He compared the meteorological doctrine of high and low pressure areas of the atmosphere, and of the movement of currents of the air, under the influence of the barometric gradient, to the Newtonian doctrine of gravitation in astronomical physics, to the Daltonian hypothesis of atomic proportions in chemistry, to the dynamic theory of the tides, and to Avogadro's law of the uniformity of the atomic constitution of gases under like conditions of pressure and temperature, and maintained that the perfection and practical application of this law must be worked out by organised and carefully thought-out plans of observation such as are now being used by the Society, and also under circumstances of higher opportunity and greater facility by the Meteorological Office of the Government. The President incidentally remarked that he believed the recent researches into the vertical circulation of the water of the ocean under the influence of the different specific gravities of its distant parts was virtually tending to the establishment of the same great influence, as being the moving spring of the physical dynamics of both the ocean and the atmosphere. The President also in allusion to the recent establishment of a Permanent Lightning Rod Committee by the Society, gave a very interesting account of a visit he had recently made to Prof. Melsens, of Brussels, and described the experiments upon which the Professor is engaged in investigating the molecular changes brought about in conducting bodies by the passage through them of powerful discharges of high tension electricity. He also gave an elaborate account of the admirable system of defence against lightning, which has been adopted at the Hotel de Ville of Brussels. Some curious and notable instances of the molecular effects of lightning discharge were exhibited during the delivery of the latter portion of the address.—The following gentlemen were elected Officers and Council for the ensuing year:—President, Henry Storks Eaton, M.A. Vice-Presidents: Charles O. F. Cator, M.A., Rogers Field, Assoc. Inst. C.E., John Knox Laughton, F.R.A.S., Capt. Henry Toynbee, F.R.A.S. Treasurer, Henry Perigal, F.R.A.S. Trustees: Sir Antonio Brady, F.G.S., Stephen William Silver, F.R.G.S. Secretaries: George James Symons, John W. Tripe, M.D. Foreign Secretary, Robert H. Scott, F.R.S. Council: Percy Bicknell, Arthur Brewin, F.R.A.S., Charles Brooke, F.R.S., Cornelius Benjamin Fox, M.D., Frederic Gaster, James Park Harrison, M.A., Robert James Mann, M.D., F.R.A.S., William Carpenter Nash, Rev. Thomas Arthur Preston, M.A., William Sowerby, F.L.S., Charles Vincent Walker, F.R.S., George Mathus Whipple, F.R.A.S.

Anthropological Institute, Jan. 25.—Col. A. Lane Fox, president, in the chair.—Annual Meeting.—The Report of Council for 1875 was read.—The following were elected to serve as Officers and Council for 1876:—President, Col. A. Lane Fox, F.S.A. Vice-presidents: Prof. Geo. Busk, F.R.S., John Evans, F.R.S., A. W. Franks, F.R.S., Francis Galton, F.R.S., Geo. Harris, F.S.A., E. Burnet Tylor, F.R.S. Directors: E. W. Brabrook, F.S.A., Capt. Harold Dillon. Treasurer, J. Park Harrison. Council: J. Beddoe, F.R.S., W. Blackmore, Sir Geo. Campbell, K.C.S.I., Hyde Clarke, J. Barnard Davis, F.R.S., W. Boyd Dawkins, F.R.S., Robert Dunn, F.R.C.S., David Forbes, F.R.S., Chas. Harrison, F.R.S.L., H. H. Howorth, Prof. T. McK. Hughes, F.G.S., Prof. Huxley, F.R.S., A. L. Lewis, Sir John Lubbock, Bart., F.R.S., F. G. H. Price, F.R.G.S., J. E. Price, F.S.A., Prof. Rolleston, F.R.S., C. R. Des Ruffières, F.R.S.L., Lord Arthur Russell, M.P., M. J. Walhouse.

Institution of Civil Engineers, Jan. 18.—Mr. G. R. Stephenson, president, in the chair.—The following paper was read:—On the ventilation and working of railway tunnels, by Mr. Gabriel James Morrison.

GENEVA

Physical and Natural History Society, Jan. 6.—M. Ernest Favre took up the discussion which has existed for ten years among geologists and palæontologists on the limit of the Jurassic and Cretaceous beds in the Alps, where the beds are not separated, as in the Anglo-Parisian basin, by freshwater deposits. Oppel, in 1865, gave the name of Tithonic stage to the beds containing Cephalopodous and Coralline faunæ, and which are found in the upper part of the Jurassic system. Geologists, mostly French, of whom M. Hébert is the best known representative, assigning a part of these deposits to the Cretaceous formation and regarding the zone of *Ammonites tenuilobatus* as Oxfordian because it is covered by Coraliferous beds, admit that there is in the Alps a great gap between the Oxfordian and the Cretaceous formations. German and Swiss geologists, on the contrary, find in the Alps the complete series of the Upper Jurassic system of the Jura. They have shown that Coraliferous is developed in nearly all the horizons of these beds, and not only in that to which D'Orbigny has given the name of Coralline stage, a name which ought to be suppressed; that the highly developed zone of *Ammonites tenuilobatus* in the Alps is Kimmeridgian, and that the Tithonic beds belong to the Jurassic formation. M. Favre has found in the Western Alps of Switzerland the complete series of these strata; he has described it in a memoir on the Upper Jurassic formation Voirons. This series has the following four divisions from below upwards:—1. The Oxford formation, properly so called. 2. The zone of *Ammonites bimammatus*, which contains many species of the zone of *Amm. transversarius*. 3. The zone of *Ammonites Acanthicus* and *A. tenuilobatus* (Astartian). 4. Tithonic beds, which are the equivalent of the Solenhofen beds. The Voirons formation includes Nos. 2 and 3. The passage from the Jurassic to the Cretaceous systems has been worked in a part of the Alps, without any interruption in the four divisions; and if we cannot find all the equivalents of the fossiliferous beds of the Jurassic basin, it should be remembered that the deposits have been placed in the former region in conditions different from those which have reigned in the second.

PARIS

Academy of Sciences, Jan. 24.—Vice-Admiral Paris in the chair.—The following papers were read:—On the decomposition of water by platinum, by MM. Sainte-Claire Deville and Debray. When a mixture of cyanide of potassium with spongy platinum is heated in a glass vessel raised to 500° or 600° near a dish of tepid water, *in vacuo*, large quantities of hydrogen are produced, and a double cyanide of platinum and potassium. A concentrated solution of cyanide of potassium attacks platinum at the boiling temperature.—Action of monohydrated sulphuric acid on alcohols, by M. Berthelot. He measures the heat liberated in such reactions.—New case of aphasia or loss of speech, arising from loss of the co-ordinated movements necessary for the act of pronunciation of words, without any lesion of the intellectual faculties, by M. Bouillaud.—On the falling in of the Cirque de Salazie, in the Isle of Réunion, by M. Sainte-Claire Deville.—On the star 70 *p* Ophiuchus, by M. Tisserand. He seeks to determine the orbit from 213 observations, comprising an entire revolution.—Report on the numbers of the *Revue d'Artillerie* submitted to examination of the Academy by the Minister of War.—Application of the mechanical theory of heat to the study of volatile liquids; simple relations between the latent heats, atomic weights, and tensions of vapours, by M. Pictet. *Inter alia*, latent heat multiplied by atomic weight (temperature and pressure being the same) gives a constant product. The difference of latent heats at any two temperatures multiplied by atomic weight is a constant number. The latent heats of all liquids are multiples of the specific heats.—Action of ammonia on rosaniline, by M. Jacquemin.—Researches on the constitution of collagenous matters, by MM. Schützenberger and Bourgeois.—Map of the globe in gnomonic projection on the horizon of the North Pole, by M. Thoulet.—On the action of cold on milk, and the products obtainable from it, by M. Tisserand. The rising of cream is quicker, and the volume of it greater, the nearer the temperature has been brought to zero; also the yield of butter is greater, and the milk creamed, butter and cheese are of better quality, the lower the temperature. The common practice might be greatly improved in this respect.—On the covariants of binary forms, by M. Jordan.—On a particular class of left inscriptible polygons, by M. Serret.—Magnetic actions on the rarefied gases in Geissler tubes (fourth note), by M. Chautard. The gaseous matter probably undergoes attraction or repulsion under action of the magnet, resulting in compression against the side of the tube and change in the physical state of the luminous stream. The alteration of the spectrum by magnetism is more marked, the greater the diameter of the tube (from $\frac{1}{10}$ mm. to 1 cm. in these experiments). With fluoride of silicium Geissler tubes, the author appears to find some indication of a new chemical reaction under magnetic influence.—On the spectrum of nitrogen and that of alkaline metals in Geissler tubes (continued), by M. Salet. He suggests that the lines described by Mr. Schuster in 1872 may have been those of sodium vapour.—On the action of heat in magnetisation, by M. Favre. Three phenomena observed:—1. Conservation of magnetism at any temperature, when the latter was maintained constant. 2. Diminution of the magnetism in cooling, at first slow, becoming very rapid after a time variable with the temperature of magnetisation. 3. Increase of the quantity of magnetism that remains after cooling, when the magnet is heated anew.—Note on a new system of electric lamp, with independent regulator, by M. Girouard.—On a new method of recording the movements of blood-vessels in man, by M. Mosso. We shall notice this separately.—Note on the development of the *Salmacina Dysteri*, Hux., by M. Giard. Several characters bring the embryo of *Salmacina* near that of Molluscs. The divergence between Molluscs and Annelids commences only after the Trochosphæra stage, and even after this there are many agreements. The parentage of Molluscs and Annelids is certainly nearer than that of the latter with Arthropods. The origin of the three groups must be sought among the Rotifers.—New fossil mammifers from the deposits of phosphate of lime at Quercy, by M. Filhol.—Influence of various elements of manures on the development of the beet, and its saccharine richness, by M. Joulie.

French Physical Society, December 17, 1875.—M. Jamin communicated the formulæ which he has established to represent the distribution of magnetism in magnets furnished with contact armature. If the armature is indefinite, the magnetic intensity in the soft iron is represented by an exponent of a single term, as in the case of magnets of very great length; if the armature is shorter the intensity is given by the sum of the two exponents. The diminution of intensity in each point of the magnet follows the same law, and the constants of the formulæ may be determined by noting on the one hand that the total loss of magnetism on the magnet is equal to the gain in the armature, and on the other hand, that the intensity at the point of contact is the same in the armature and in the magnet.

VIENNA

Imperial Academy of Sciences, Dec. 16, 1875.—On differential air thermometers, by M. Pfaundler. Berthelot's air thermometer with capillary manometer has the drawback, that its data depend on the existing barometric state. M. Pfaundler seeks to obviate this by his differential air thermometers. He gives various constructions of these.—On new fish species from the collections of the Imperial Zoological Museum, by M. Steindachner. Mostly species of siluroids from the Bay of Panama, &c.—On the flow of stratified clay under bodies pressed into it, by M. Obermayer.

THURSDAY, FEBRUARY 10, 1876

OLD AND NEW WORLD SPIDERS

Descriptions of Several European and North-African Spiders. By T. Thorell. Kongl. Svenska Vetenskaps. Akademiens Handlingar, Bandet 13, n. o. 5, pp. 1—203. (Stockholm: Norstedt and Söner, 1875.)

A Collection of the Arachnological Writings of Nicolas Marcellus Hentz, M.D. Edited by Edward Burgess. With Notes and Descriptions by James H. Emerton. Forming No. II. of Occasional Papers of the Boston Society of Natural History, pp. 1—171, Pl. 1—21. (Boston: U.S.A., 1875.)

IT is a somewhat singular coincidence that the two works at the head of this article should have been published just about the same time. We shall endeavour briefly to show the value and bearing of each.

It is probably undeniable that an illustrated book on any branch of natural history is more acceptable to the public—certainly more attractive—than one wholly devoid of pictorial illustrations; and not without good reason, for it is well known what great assistance even the advanced student obtains from a single glance at an illustration, when traced by a hand well cognisant of the point sought to be illustrated, even though the hand may be entirely wanting in artistic power. The want, however, of drawings to assist the comprehension of the dry details of natural objects may be reduced to a minimum by the presence of good diagnoses. Pleasant are those pages where both these helps exist; dreary and uninviting indeed (though sometimes inevitable) are long and dry details of form, structure, and colour, when unenlivened either by drawings or diagnoses. From such dreariness Dr. Thorell's two hundred quarto pages of descriptions of spiders (under the title given at the head of this notice) are saved by the excellent diagnosis with which each description is preceded. It not unfrequently happens that a diagnosis is a mere formal abstract of the longer description that succeeds it; this is, however, not the case in the present instance, where each diagnosis puts before us just such distinctive points of special form, structure, and colour as the describer, were he at all able with his pencil, would endeavour to delineate by means of rapid sketches and dissectional drawings.

In respect to this point Dr. Thorell remarks (p. 4), that he has "prefaced his descriptions with *diagnoses*, although this is not done by the generality of modern arachnologists," it is, he says, "my firm conviction that tolerably good diagnoses very greatly facilitate the determination of unknown species, even though they be not real [by the term *real* Dr. Thorell appears to mean *full*] definitions." This places a diagnosis, in relation to the full description, exactly on a par with the part delineation and dissectional drawing when compared with a full artistic illustration; neither the diagnosis nor the dissectional drawing, however characteristic, precludes the necessity for a full description, nor for a full artistic illustration where it can be had; in fact, were it not a serious question of space and cost, amounting often to a positive bar, no natural object could be said to be well and properly described and illustrated without *a diagnosis*, such as that mentioned above, *a full description* embracing an almost photographic accuracy of every part, and (where closely allied forms exist) *a differential description* as well, besides full, and dissectional drawings. Of course the full description would be broken up into ordinal, family, generic, and specific characters, each in their proper place; the three first only requiring repetition where, in the individual examples, they happened to depart from the strict type.

The introductory pages of the work before us are in English, while the descriptions are in Latin; and the materials from which Dr. Thorell has drawn them up have been gathered from various collectors and widely distant parts of Europe, including the northern shores of Africa; which last, under the term "Mediterranean Basin," Dr. Thorell rightly joins to Europe as a single zoological province. 202 species, belonging to 51 genera, distributed among 12 families, are described, 24 of the species being given as new to science; a large proportion of the remainder, together with four new genera, having been published as new but a short time before, under the title "Diagnoses Aranearum Europæarum aliquot Novarum Scripsit." T. Thorell, in Tijds. voor Entom. Deel. xviii., 1875.

Dr. Thorell states (p. 1) that he follows here, with some slight modifications, the classification proposed in his former work "On European Spiders;" this mention gives rise to a long foot-note, of two closely-printed pages, in which he examines and criticises M. Eugène Simon's strictures of his system (published in "Aran. Nouv. ou peu Connus du Midi de l'Europe," 2e Mém.; "Mém. Soc. Roy. de Sciences de Liége," 2e ser. t. v., 1873). It is not necessary to enter here into the merits of this little passage of arms, but we come to the conclusion, on perusing it, that Dr. Thorell is probably right in saying that he "has not been so fortunate as to make himself understood" by M. Simon. At page 7, the latter author's theory respecting the eyes of spiders is discussed in another long foot-note. This theory has already been noticed in these columns (vol. xi., p. 224). Dr. Thorell, while entering fully into the question of the real nature and structure of the eyes of spiders, says, with regard to this theory, that "it is to be wished that M. Simon would somewhat more accurately describe the researches on which his views are founded; his theory is, in fact, so much the more remarkable, as no previous naturalist who has investigated the finer structure of the eyes of spiders, appears to have been aware of the existence of any distinction between day-eyes and night-eyes." Independently, however, of M. Simon's theory, the question as to the nature of spiders' eyes is a very interesting one; and very valuable would be those researches which should reveal to us the actual anatomical condition of such eyes as, for instance, the apparently atrophied, and probably useless, ones of the hind-central pair in the genus *Oecobius*, Luc.

A footnote of considerable length is appended to pages 66 and 67 on the venom of various species of the genus *Lathrodectus*, comparing it with the reputed venom of *Galeodes araneoides*, and questioning the correctness of M. Simon's conclusions (Mém. Soc. Roy., Liége, 2 ser. t. v.), that the bite of *Lathrodectus* 13-*guttatus* is not poisonous. Another point, also of great interest, is noted at p. 65, where Dr. Thorell speaks of traces of segmenta-

tion (somewhat like that of the abdomen of the *Phalangidea*) in the shape of an encircling furrow towards the hinder extremity of the abdomen of some species of *Lathrodectus:* and he refers to the known fact of the segmentation of the abdomen in the *embryo* of spiders (Claparède, "Recherches sur l'Evolution des Araignées"). Still plainer evidences of obsolete segments have been previously noted in *Erigone corrugis*, Cambr. (Proc. Zool. Soc., March 1875, p. 214, Pl. XXIX. Fig. 21), as well as in some other species of the same genus.

Were it not for points thus incidentally raised, and some of which have been above noticed, Dr. Thorell's present work would be of little interest except to the arachnological specialist; by such, however, it will be hailed as an important and valuable addition to the literature upon European spiders; while a more general interest is imparted to it by the topics here commented upon.

It is one of the disadvantages attending the publication of papers on natural history in periodical journals that such papers are more or less inaccessible to those who either do not possess the journal, or who live at a distance from a library containing it; and this disadvantage is heightened when a series of papers, extending, perhaps, over many years, is thus issued, on any one subject. Araneologists are therefore greatly indebted to the editor of Prof. Hentz's writings, for clearing away a disadvantage of this kind, and one which has been much felt for a considerable period.

Prof. Nicolas Marcellus Hentz, a Frenchman by birth, but obliged to fly his native country at the downfall of the first Napoleon, devoted much time and labour in the United States, the land of his adoption, to the study and collecting of spiders. After having published some few short papers upon them, at length, in 1841, he brought together the whole of his notes and drawings, publishing them in a series of papers in the Journal of the Boston Society of Natural History, at intervals from that year to the year 1850. These papers, eight in number, and contained in three vols.—iv., v., and vi.—of the Boston Journal, together with two or three other papers previously published, and an unpublished[1] supplement, have now been collected and given to the public in the present volume.

Considerable difficulties attended the attainment of this result, especially in regard to the plates; the stones from which the lithographic plates were taken having been destroyed and several of the copper plates lost. The science of photography, in the shape of the Albert-type process, has, however, enabled the editor very successfully to overcome this difficulty, and the facsimile plates produced by it are only second to those of the original papers. In order to enable araneologists to refer to and quote the exact page and plate of the original papers, care has been taken to preserve the old pagination by numbers (within brackets) inserted in the text, and to retain the original numbering of the plates alongside of the numbers referring to the present volume. The matter of the supplement has been worked into the different descriptions, wherever it happened to belong, though still kept separate by means of brackets. With this exception, and the addition of some short notes (referring chiefly to the dimensions and the occurrence of the species) by Mr. J. H. Emerton, Hentz's papers are thus now reproduced just as they were originally written and published by himself.

With regard to the subject matter of this volume, the author appears to have relied more upon the accuracy of his drawings (which were fully coloured, and said to be artistic and of great beauty) than to his descriptions for making known the spiders he discovered; his descriptions consequently are very meagre and unsatisfactory, while the engraved plates cannot be considered to do much justice to the original drawings, if the latter were, as above mentioned, artistic and beautiful; the figures in the plates, though neat, being for the most part very flat and inartistic. It is not meant by this that their utility in the determination of the spiders delineated is much, if at all, impaired; on the contrary, it will probably be found for the most part sufficiently easy for collectors to determine their captures by reference to the figures given. Every description is followed by some observations on the habits and economy of the spider, showing that the author's great pleasure was not merely in the collecting and depicting, but also in observing, the objects of his pursuit.

The system of classification adopted by Prof. Hentz is now a matter of quite secondary importance; though some (probably most) of the genera which he characterised as new, will stand; and so perhaps will the greater number of his species. The total number—254—of spiders described and figured must be considered small compared with the wide area over which they were collected; the larger number, however, appear to have been found in North Carolina and Alabama, with some few from Massachussetts and Georgia. A little vigorous collecting in those localities will doubtless soon lead to the identification of most, if not of all, of the spiders contained in Prof. Hentz's papers, and, with even less doubt, will greatly add to their number.

In thus speaking of Hentz's labours as an araneologist in the United States, it must not be forgotten that the late Dr. Abbott left behind him, many years ago, an extensive series of beautiful drawings of Georgian and other North American spiders; all of these were named and shortly described by Baron Walckenaer in vols. i. and ii. of his "Insectes Aptères" (Paris, 1837). The British Museum possesses a set of these drawings, but whether this is the original set from which Walckenaer's descriptions were derived, or whether (as we have understood) his descriptions were made from another set given to him by Dr. Abbott, and now existing in one of the public institutions of Paris, appears to be uncertain. At any rate the set of drawings in the British Museum Library bears every appearance of being an original, even if a duplicate, set; and it would perhaps be feasible, as well as worth while, now to publish these drawings as a whole, with the names and descriptions given by Walckenaer. Such a volume, in conjunction with that formed by Hentz's papers, would represent very nearly all that has been done in the past to North American Araneology, and would form a secure foundation and starting-point for the efforts of the future.

It must not be omitted to mention that the two last

[1] This supplement was published, however, latterly, under the editorial care of Mr. S. H. Scudder, in Proc. Bost. Soc. Nat. Hist., xi., pp. 103—111, Pl. 1, 2, 1867.

plates in the present volume are original ones from the skilful pencil of Mr. J. H. Emerton; these suffer in some measure (as do also some of the others) from their production by the Albert-type process; but in point of accurate detail and artistic finish their figures are immeasurably in advance of those engraved from Hentz's drawings. It is to Mr. Emerton, who appears to have resolutely entered upon the field of araneology, and to his great powers of delineation, that the arachnologists of the Old World now look for the thorough working out and illustration of the Spiders of North America.

O. P. C.

DYEING AND CALICO PRINTING

Dyeing and Calico Printing, including an Account of the Most Recent Improvements in the Manufacture and Use of Aniline Colours. By the late Dr. F. Crace-Calvert, F.R.S., F.C.S. Edited by John Stenhouse, LL.D., F.R.S., &c., and Charles Edward Groves, F.C.S. (Manchester: Palmer and Howe; London: Simpkin, Marshall, and Co., 1876)

THE subjects treated of in the volume now before us possess a twofold interest—first as involving questions of pure science in the domain of organic chemistry; and secondly, as being of immense industrial importance to the country. It does not enter into our province to notice the work in its industrial aspect, but we have no hesitation in stating that author and editors have performed their task in a highly creditable manner. From every point of view the work will be found useful, and we can recommend it to the scientific chemist as well as to dyers and calico printers.

The author, who died in 1873, had been occupied up to the time of his death in preparing a treatise on colouring matters other than aniline. The present work has been edited from the author's MSS. with the addition of five chapters, forming a considerable portion of the book, on the coal-tar colours, by the editors.

The mode of treatment pursued is nearly the same for each dye. The natural history and source of the material from which the colour is obtained are first given, then the chemical composition and mode of preparation or manufacture, and finally the method of application to the various fabrics described. The whole subject is profusely illustrated by specimens of dyed and printed fabrics pasted into the book.

The work is appropriately prefaced by an obituary notice of the author. The first chapter treats of colour in general and the action of different forces, chemical agents, &c., on the various colouring matters. We must object to the definition of colour given in this chapter. It is defined as "the impression that the light reflected from a surface makes upon the eye," thus excluding all cases in which colour is caused by *absorption*.

Chapters II. and III. are entirely devoted to madder dyes, and contain, among much valuable chemical information, a description of Prof. Stokes's optical tests for alizarin and purpurin. The method of dyeing in Turkey red and the action of different mordants in madder and garancin printing is clearly explained, and the manufacture of artificial alizarin described. Chapter IV. treats of the red dyewoods—logwood, sapan, Lima, peach, and Brazil woods; also of safflower and alkanet. Chapters V. and VI. are devoted to indigo—this portion of the subject being described in considerable detail. Chapter VII. contains accounts of cochineal, kermes, gumlac, lac dye, lac lake, and murexide, while Chapter VIII. treats of orchil, cudbear, and litmus. In Chapter IX. some of the important yellow colouring matters are treated of, such as quercitron, fustic, Persian berries, weld, aloes, turmeric, annatto, &c.; while tannin matters form the subject of Chapter X., the most important of these being sumach and catechu. Chapter XI. contains descriptions of the methods employed for testing and determining the commercial value of particular samples of the various dyestuffs. In this chapter will be found described some of the different forms of "colorometers" which have been devised for estimating the colouring power of dyes.

The portion of the work devoted to the coal-tar colours commencing with Chapter XII. begins with an account of the various bodies which have been found in coal-tar. A list of thirty-eight distinct compounds is given, and many more doubtless exist. The most important substance produced in the dry distillation of coal, so far as the dye manufacturer is concerned, is benzene. The conversion of this substance into aniline is explained, and the manufacture of magenta described, the chapter concluding with an account of safranine and some other aniline reds. Chapter XIII. treats of aniline violets, and blues such as mauve, the Hofmann and methyl-aniline violets, diphenylamine, and Nicholson's blues, &c. In Chapter XIV. we have a description of the greens, aldehyde, iodine, and methyl-aniline and the aniline yellows, phosphine, zinaline, &c. Chapter XV. treats of aniline black and brown, and the concluding chapter is devoted to the phenol, cresol, and naphthalene colours, including picric acid, corallin, aurin, and others. Not the least useful portion of the book will be found the tables at the end, which consist, first of a list of the madder-colouring matters, their formulæ, and reactions, and then a series of tables, which will enable the analyst to distinguish the different colours when fixed on fabrics.

The above imperfect sketch of the present volume will enable our readers to form an idea of the immense number of distinct compounds used in dyeing and calico printing, and the apparently heterogeneous nature of the products, both natural and artificial, called upon to furnish materials for these arts. It must not be forgotten that the enormous development of these industrial arts within the last few years is entirely due to researches undertaken in the first instance without special regard to the commercial aspects of the questions involved—witness the accidental discovery of mauve, the first of the aniline dyes, in the course of an investigation for obtaining quinine by artificial means.

The manufacture of alizarin, the colouring principle of madder, is another triumph of organic chemistry, of which the present generation may justly be proud. It is perhaps not going too far to look for a similar achievement with regard to indigo—in point of fact we may remind our readers that the colour-giving principle of this substance has already been synthesised by the following series of reactions.

A mixture of dried calcium, acetate, and benzoate is

submitted to distillation in order to obtain the ketone known as acetophenone :—

$$\mathrm{Ca}\left\{\begin{matrix}OC_2H_3O\\OC_2H_3O\end{matrix}\right. + \mathrm{Ca}\left\{\begin{matrix}OC_7H_5O\\OC_7H_5O\end{matrix}\right. = 2CO\left\{\begin{matrix}CH_3\\C_6H_5\end{matrix}\right. + 2CaCO_3$$

Calcium acetate. Calcium benzoate. Methyl-phenyl ketone. Calcium carbonate.

Methyl-phenyl ketone when treated with fuming nitric acid yields two isomeric nitro-derivatives, $C_8H_7(NO_2)O$, one of which when heated with a reducing mixture composed of zinc dust and soda lime is converted into indigo blue :—

$$\underset{\text{Nitro-acetophenone.}}{2C_8H_7(NO_2)O} - 2H_2O - O_2 = \underset{\text{Indigo blue.}}{C_{16}H_{10}N_2O_2}$$

The process above given is at present only valuable from a scientific point of view, since the yield of indigotin is but small. It yet remains to convert this laboratory reaction into a practicable process, in order to do for indigotin what has already been accomplished for alizarin, and thus completely revolutionise another large branch of the colour-producing industry.

R. MELDOLA

OUR BOOK SHELF

Scientific Culture. By Josiah P. Cooke, Jun., Professor of Chemistry and Mineralogy in Harvard College (U.S.). (London: H. S. King and Co., 1876.)

THIS is altogether an admirable address, characterised by real eloquence and by clearness and decision of view as to the place which science ought to occupy in any system of education. Most of Prof. Cooke's audience were teachers by profession, attending Harvard University mainly to become acquainted with the experimental methods of teaching physical science. We commend the address not only to scientific students and teachers of science, but to all who take an interest in education, and to all students who desire a clear statement as to what, in the not distant future, will be regarded as the only liberal education, an education in which science will be allotted a place of at least equal importance with that of literature. What Mr. Cooke's views are on certain matters which have for long been discussed in this journal, may be learned from the following extracts. On the place which Science ought to occupy in education, he says :—

"I must declare my conviction that no educated man can expect to realise his best possibilities of usefulness without a practical knowledge of the methods of experimental science. If he is to be a physician, his whole success will depend on the skill with which he can use these great tools of modern civilisation. If he is to be a lawyer, his advancement will in no small measure be determined by the acuteness with which he can criticise the manner in which the same tools have been used by his own or his opponent's clients. If he is to be a clergyman, he must take sides in the great conflict between theology and science, which is now raging in the world, and unless he wishes to play the part of the doughty knight, Don Quixote, and think he is winning great victories by knocking down the imaginary adversaries which his ignorance has set up, he must try the steel of his adversary's blade. . . . .

"I feel that any system of education is radically defective which does not comprise a sufficient training in the methods of experimental science to make the mass of our educated men familiar with this tool of modern civilisation; so that when, hereafter, new conquests over matter are announced, and great discoveries are proclaimed, they may be able not only to understand but also to criticise the methods by which the assumed results have been reached, and thus be in a position to distinguish between the true and the false. Whether we will or not, we must live under the direction of this great power of modern society, and the only question is whether we will be its ignorant slave or its intelligent servant."

On the uses to which Universities should be put, Mr. Cooke's opinions are decided :—

"The time has passed when we can afford to limit the work of our higher institutions of learning to teaching knowledge already acquired. Henceforth the investigation of unsolved problems, and the discovery of new truth, should be one of the main objects at our universities, and no cost should be grudged which is required to maintain at them the most active minds in every branch of knowledge which the country can be stimulated to produce.

"I could urge this on the self-interest of the nation as an obvious dictate of political economy. I could say, and say truly, that the culture of science will help us to develop those latent resources of which we are so proud; will enable us to grow two blades of grass where one grew before; to extract a larger per cent. of metal from our ores; to economise our coal, and in general to direct our waiting energies so that they may produce a more abundant pecuniary reward. . . . This is all true, and may be urged properly if higher considerations will not prevail. It is an argument I have used in other places, but I will not use it here; although I gladly acknowledge the Providence which brings at last even material fruits to reward conscientious labour for the advancement of knowledge and the intellectual elevation of mankind. I would rather point to that far greater multitude who have worked in faith for the love of knowledge, and who have ennobled themselves and ennobled their nation, not because they have added to its material prosperity, but because they have made themselves and made their fellows more noble men."

These are but small samples of the many good things contained in Prof. Cooke's address, which we should like to see in the hands of all students. The latter portion of the address students of mineralogy will find of special value.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

On the most Northerly Latitude at which Land and Freshwater Molluscs have hitherto been found

I AM very sorry that I have involuntarily made a mistake in a letter to Mr. Oscar Dickson (NATURE, vol. xiii. p. 96), in which it is stated that Dr. Stuxberg had found a Physa on the most northerly locality from which land and freshwater molluscs have hitherto been obtained. When I made this statement I had not Middendorff's "Sibiritche Reise" with me, and I did not then remember that this celebrated naturalist had found a species of the same genus on the Taimur peninsula north of the seventy-third degree N.L.

A. E. NORDENSKJÖLD

Stockholm, Jan. 29

Prof. Tyndall on Germs

HAVING commented elsewhere (*Lancet* and *Brit. Med. Journ.* Feb. 5) upon Prof. Tyndall's recent attempt to establish the truth of the Germ Theory of Disease, my remarks in your columns may be very brief.

Prof. Tyndall tells the public he has uniformly failed to obtain evidences of putrefaction in previously boiled organic infusions protected from contamination by atmospheric particles.

The following investigators have, however, with one or other fluid, been able to obtain such results :—

1. Schwann, *Isis*, 1837; Poggendorff's *Annalen*, 1837.
2. Mantegazza, *Giorn. dell. R. Istit. Lombard.*, t. iii., 1851.
3. Schroeder and Dusch, *Annal. de Chimie*, tome xli., 1854.
4. Schroeder, Liebig's *Annalen*, cix., 1859, and *Chem. News*, vol. v., 1862.

5. Pouchet, *Hétérogénie*, 1859, and *Nouvelles Expériences*, &c., 1864.
6. Pasteur, *Ann. de Chimie*, 1862 (see pp. 60-62),
7. Joly and Musset, *Compt. Rend.*, 1861 and 1862.
8. Jeffries Wyman, *American Journal of Science*, vol. xxxiv., 1862, and vol. xliv., 1867.
9. Victor Meunier, *Compt. Rend.*, tome xli., 1865.
10. Child, *Proceed. of Roy. Soc.*, June 1864, and April 1865.
11. Hughes Bennett, *Ed. Med. Journ.*, 1868.
12. Cantoni, *Gaz. Med. Ital. Lombard.*, tome i., 1868.
13. Bastian, NATURE, 1870; *Modes of Origin*, &c., 1871; *The Beginnings of Life*, 1872.
14. Burdon Sanderson, NATURE, Jan. 8 and June 1873; *Med. Times and Gaz.*, Oct. 22, 1873.
15. Huizinga, NATURE, March 20, 1873, and Pflüger's *Archiv*, vols. vii. and viii.
16. Lankester and Pode, *Proceed. of Roy. Soc.*, vol. xxi., 1873.
17. Roberts, *Phil. Trans.*, vol. clxiv., 1874.
18. Samuelson, Pflüger's *Archiv*, vol. vii., 1874.
19. Gscheidlen, quoted by Dr. Sanderson in *Academy*, July 10, 1875.

I have set down the names in order of time, and included my own amongst them because those mentioned after me have all confirmed my results with regard to the putrefaction of some fluids in hermetically sealed vessels, from which the air has been expelled by boiling; the very experiments, in fact, which Prof. Tyndall now endeavours to impeach by his own one hundred and thirty-nine failures.

Dr. Burdon Sanderson's well-known corroboration of the accuracy of my results may be here reproduced. He says (NATURE, January 8, 1873):—"The accuracy of Dr. Bastian's statement of fact with reference to the particular experiments now under consideration has been publicly questioned. I myself doubted it, and expressed my doubts, if not publicly, at least in conversation. I am content to have established—at all events, to my own satisfaction—that, by following Dr. Bastian's directions, infusions can be prepared which are not deprived by an ebullition of from five to ten minutes of the faculty of undergoing those chemical changes which are characterised by the presence of swarms of Bacteria, and that the development of these organisms can proceed with the greatest activity in hermetically sealed glass vessels, from which almost the whole of the air had been expelled by boiling."

And, if Prof. Tyndall and others wish to know how far these results have since been generally recognised as correct, reference may be made to a review of my work, "Evolution and the Origin of Life," by Dr. Burdon Sanderson, in the *Academy* of July 10, 1875. There, in reference to the confirmation which these experiments had received, and in relation to other work in connection with the question generally by Samuelson and Gscheidlen, Dr. Sanderson writes:—"As regards the trustworthy character of the experiments themselves, it will probably be a sufficient guarantee to most readers that they have been conducted under the immediate supervision of men like Pflüger and Hoppe-Seyler, who occupy the foremost rank as vital physicists. Those who are more especially interested in the subject will best satisfy themselves of the exactitude and completeness with which all the investigations have been carried out by reading for themselves the original papers."

Although Dr. Sanderson thus thoroughly recognises the fact (and knows that others do the same) that many boiled fluids will putrefy in closed vessels from which air has been expelled by boiling, it is well known that he is not willing to regard such facts as the proof of the occurrence of "spontaneous generation." He admits, indeed (*British Medical Journal*, February 13, 1875, p. 201), that I and others have shown that Bacteria in their "ordinary state" are killed by a temperature of about 140° F.; but, instead of accepting "spontaneous generation" as an explanation of the occurrence of living organisms in the vessels above referred to, he pleads in favour of the only other possible explanation, viz., a "latent vitality" in some Bacteria-germs not extinguishable by exposure for ten minutes or so to the influence of boiling water. I felt it my duty to refer to this hypothesis in my address at the Pathological Society last year (*British Medical Journal*, April 10, 1875, p. 473); but, whatever its worth may be, Dr. Sanderson, whose learning and knowledge of the whole question few will dispute, knows that this, or some such hypothesis, alone stands in the way of the acceptance of "spontaneous generation" as a proved reality.

Prof. Tyndall, however, seems to regard this hypothesis as undeserving of notice. He makes no sort of reference to it, and agrees with me in thinking that Bacteria and their germs are decidedly killed by five minutes' boiling in organic infusions. He still further supports the view held by me, in opposition to that of M. Pasteur, that such a result follows both with alkaline and with acid infusions.

This may seem to many of my readers a rather remarkable finale when compared with Prof. Tyndall's own anticipations; but I feel thoroughly assured that those who understand the subject will see that, in the present stage of the controversy, no other conclusions of value are deducible from his recent experiments. He appears to have completely misapprehended the present state of knowledge on the question; he has uniformly failed to obtain results which are now firmly established; and, as regards the only question which is at present in dispute, he unhesitatingly coincides with me.

Feb. 7 H. CHARLTON BASTIAN

I HAVE read with great interest and pleasure Prof. Tyndall's paper on Germs. But I am troubled on one point. I am sure Prof. Tyndall will not think my difficulties unworthy of attention and removal, though I confess that I am only one of that unpretending class to whose enjoyment and instruction he has devoted so large a share of his valuable time. I am an outsider in scientific research; I delight to follow every investigation which tends to the development of science; but I have not the time, and, if time were available, perhaps I should find that I had not the skill to conduct experiments for myself. I have to trust—and I have seldom found myself misled by trusting—to the recorded experiments of men whose reputation has been established by prolonged and valuable work. I cannot willingly give up this trust, and yet there is one passage in Prof. Tyndall's paper which almost forces me to do so. He tells us that in 139 instances he boiled organic solutions in flasks which were then hermetically sealed, and that in no one case did putrefaction accompanied by Bacteria occur. The inference he draws from this "cloud of witnesses" is that Bacteria cannot be developed in flasks so treated.

Precisely the opposite conclusion appears to have been arrived at by Prof. Burdon Sanderson (NATURE, vol. vii. p. 180). He also tested organic fluids in flasks boiled and hermetically sealed, and he found that putrefaction, with swarms of Bacteria, frequently followed. He considered it established that the development of Bacteria could proceed with the greatest activity in hermetically sealed glass vessels previously subjected to boiling heat.

I observe that Prof. Tyndall suggests that such contradictory results may be explained by "errors of preparation or observation." No doubt they may, but it would be a great shock to my scientific faith to be driven to this theory to explain apparent discrepancies between such observers as Professors Tyndall and Sanderson. I cannot help, not only hoping, but believing that there must be some way of reconciling the experiments of two such eminent inquirers, and I should be much perplexed if I were compelled to form an opinion whether the supposed error, if it does exist, ought to be attributed to the one or the other.

Can Prof. Tyndall relieve me from the necessity of believing that either went astray in his work? May there not have been some variations in the conditions which would allow us to accept both sets of experiments as sound? On carefully comparing the two I find that Prof. Tyndall's experiments are far more numerous than those tried by Prof. Sanderson. On the other hand, I find that Prof. Sanderson describes with admirable precision all the details of his work. Perhaps it scarcely fell within the scope of Prof. Tyndall's discourse to descend to such minutiæ, but it may very well be that a more particular description, such as that which Prof. Sanderson published, of his treatment of the hermetically-closed flasks—as to the preparation of the solutions, and their specific gravity, the mode and duration of the heating, the method and temperature of the developing treatment, and the like—would supply the means of reconciling his results with the apparently contradictory results arrived at by his brother professor.

When we are considering the conclusions of men of science of the highest calibre I do not think that over much weight should be attached to their preconceived expectations. Still, so far as they go, the avowed opinions of Prof. Sanderson before trying his experiments do tend to reinforce their value. He obtained results which he did not anticipate, and that after taking very careful precautions to exclude the possibility of errors of observation. The errors may have crept in notwithstanding, but it is especially uncomfortable to us outsiders to think

this possible, and I for one cannot believe it until I know whether the conflict between the two professors may not be explained by differences in the conditions under which they worked.

We all know how fully Professor Tyndall's time is occupied, but I hope it is not too much to ask him, in the interests of science, and for our instruction, to add to the scientific value of his experiments on hermetically sealed flasks by publishing the details, so as to enable us to compare them with the careful account which Prof. Sanderson gives of his, and to judge whether we ought to trust the one or the other or—what would be the more agreeable, and I cannot help thinking the more likely, consequence—to trust them both in this as we have done in so many previous investigations.

INQUIRER

The University of London and School Examinations

HAVING given some assistance to the preparation of the Report referred to in your leader of the 3rd inst., I shall be glad if you will allow me to correct the somewhat erroneous impression which I fear your article is likely to produce.

It was with some surprise that I found the Report of the Sub-committee of the Convocation of the University of London forming the subject of an editorial notice, seeing that, as yet, it is private matter printed only for circulation among the members of the University. At the recent meeting of Convocation I endeavoured to explain the position which the Annual Committee occupied with respect to this Report; and from the absence of all reference to the subject in the notices of the meeting which appeared in the daily papers, I had reason to think that I had succeeded in showing why the matter was not yet ripe for publication. In answer therefore to your query: "But is it easy to speak with reasonable seriousness of an attitude like that which the Annual Committee has adopted?" I need now only state, with respect to the Report, that it is not yet adopted by Convocation nor by the Annual Committee.

But I am inclined to think that you have lacked the opportunity of carefully studying the proposals of the Sub-Committee, or you would not have found it necessary to speak of them in terms of "irony" or "levity."

Your article suggests that the University of London has been asked to adopt a scheme for the examination of schools with no higher motive than that of "entangling schoolboys in its meshes," and of withdrawing them from the influence of the other Universities; and to establish this position you quote a passage from one of the paragraphs of the Report, in which, *inter alia*, it is stated that unless the University of London is prepared to take some part in the examination of schools "*the number of candidates for the London examinations will sensibly decrease*," which last words you have printed in italics, although in the Report itself no such prominence is given to them. It is quite true that the graduates of Burlington Gardens consider that the influence which their examinations exert on education is, on the whole, beneficial. They are consequently desirous that that influence should if possible be extended, and would view with regret, as the Report suggests, any cause that might tend to dissociate from the University of London those schools which hitherto had acted as feeders to it. But is it quite fair to characterise this honest endeavour to improve school-teaching as an attempt to *entangle schoolboys within the meshes of the University?*

Your article further states that the Annual Committee have not a word to say as to the efficiency of the work in which the ancient Universities have for many years been successfully engaged. Indeed they have: but it is not likely to be found in the Report of the Sub-committee. The several weighty reasons which have induced Convocation to request the Senate to undertake the examination and inspection of schools have been repeatedly and fully discussed by Convocation and its Committee; and the result of these discussions has been the appointment of a Sub-committee for the purpose of suggesting what might seem to them the best and most comprehensive system of examination. Nothing would be easier, in reply to your article, than to show how the proposals embodied in the Report of the Sub-committee, if ultimately adopted by the Senate, would tend to the improvement of secondary education, and would entitle the University of London to receive that "debt of gratitude" which you say "the nation would owe it," if it undertook in good faith to offer to schools a better system of examination than they at present possess. But I am not at liberty to publish the contents of a Report which is at present nothing more than a series of recommendations which the Annual Committee have accepted as the basis of conference between Convocation and the Senate. I may, however, be permitted to refer to one important feature in that Report which I might have expected would have gained for it the support of a scientific journal such as NATURE—that in the examinations for certificates the same weight is given to Science as to Languages and Mathematics. If the University of London should determine to undertake the new duties to which the Report refers, many schools would be enabled to choose between two systems of examination differing in many essential particulars from each other; but what is more important is the fact that the scheme of the University of London would cover a far wider range of schools than is included within that of the Joint-Board of Oxford and Cambridge; and that those schools which stand most in need of careful inspection would, for the first time, have the opportunity of being affiliated to a University.

In conclusion, permit me to add, that so far from desiring to compete with the older Universities, the Senate of the University of London expressed a strong desire to co-operate with Oxford and Cambridge in their great educational work; and it was not till after the Joint-Board had given reasons why they were unable to act in conjunction with London, that independent action was even suggested.

PHILIP MAGNUS

Feb. 5

WILL you spare me a few lines of space to reply to your first article of Thursday last? A portion of that article was directed against examinations in general, and would apply to the Oxford and Cambridge scheme, as well as to that put forward by our Sub-committee; far more so, in fact, as an important part of our scheme relates to inspection of methods of teaching, school-books, &c., which is not included in the conjoint scheme of the older Universities. Our object is to improve the education given in schools other than primary; and if the author of your article will suggest any method besides examination and inspection by which this may be effected, we will gladly give it our earnest consideration.

Our Report was drawn up for the Annual Committee of Convocation, and not for the outside world. It was not necessary for us to inform Convocation that the University of London has a tradition and principles of its own, principles distinct from, and sometimes antagonistic to those of Oxford and Cambridge. Among these traditional principles are, firstly, that all education ought to be *many-sided*, and not solely either mathematical or classical, and secondly, that Science ought to hold a place co-ordinate with Language and Mathematics. It was not necessary for us to point out to Convocation that if the number of candidates for the London examinations were sensibly to decrease, these two principles would have a diminished influence upon the education of the country, for there is in Convocation a strong attachment to these principles, and a vivid appreciation of the *raison d'être* of the University. Neither was it necessary for us to state what we thought the deficiencies of the Oxford and Cambridge Local Examinations. It was upon the ground that these examinations tended to become too much "an end instead of a means" that we were commissioned by Convocation to draw up a scheme, under which we should rather inquire whether the schools have done well what they profess to have done than dictate to them what course of studies they should pursue. A careful comparison of our scheme with that of the Conjoint Board will make the divergence of aim apparent.

And now we are advised to admit that we have no independent mission as a University, and to stand by to see whether or not the older Universities will do our work, on the ground that it would be a "more dignified course." Dignity and usefulness often appear to stand in inverse relation one to the other. The University does not exist for the sake of being dignified, but of doing work; and the scheme we have elaborated will, if carried out, do work not even proposed by the Conjoint Board. That Board is intended to deal only with such schools for boys as have a governing body, whereas our scheme includes "private adventure" schools both for boys and for girls.

Finally, I may be allowed to express my surprise that NATURE should desire the one University which gives Science its true position to stand aside, and should characterise our wish to assert and to spread its distinctive principles as "cynical."

Hampstead, Feb. 5

H. A. NESBITT

[THE Convocation of the University of London is a very large body, and its proceedings, are reported in the daily papers. A

document which was communicated to every member of that body, and the consideration of which formed part of its proceedings, can only by a legal fiction be described as confidential. But the plea that the document was confidential practically abandons the defence of it. A really statesmanlike paper on a matter which affects all the higher grade schools of the country would gain rather than lose by publicity.

The course which Convocation has under consideration has no doubt, as our correspondents point out, much to be said in its favour. But the reason actually put forward in the preamble of the Report as a ground for taking action, is from the point of view of public policy simply indefensible. It would be appropriate enough if the Report had been addressed by a Board of Directors to the shareholders of a Limited Liability Company, because in the fashion characteristic of such documents it treated the matter in hand from the strictly business point of view of the "concern." It is this attitude which we described as cynical. And we must repeat that it is not in our opinion decorous that a matter gravely affecting the higher education of the country should be treated simply as a question of the falling off of examiners at one particular centre of examination. If it is not the duty of a University to be dignified, it is at least the duty of its advisers to be statesmanlike; and if we may have done injustice to the real desires of the framers of the Report, they have only their own inadequate expression of them to blame.—ED.]

Public Analysts

IN your last week's issue your correspondent, Mr. M. Williams, writes in such terms as would lead your readers to suppose that much less has been done in the matter of butter analysis than is really the case.

I have not the letter before me at this moment, and therefore speak from memory, but I believe that your readers are led to understand that no analyses of pure butter and of pure butter mixed with known quantities of foreign fats have been published. In this he is mistaken, for in a little work published in 1874, the details of eleven experiments upon butters known to be pure are given. The samples were purchased from outlying country farms in the Isle of Wight, and the results of the analyses fairly prove the constancy of the fixed fatty acids in butter.

It is also shown that all foreign fats likely to be used as adulterants are constant in their composition, and that they yield a much larger percentage of fixed acids than does butter; the range of difference being wide enough to offer a practical basis upon which to found accurate estimations of foreign fats in factitious butters. Many admixtures were made, and the published results of the analyses prove the practicability of the method employed. Your correspondent hints that no one dares to undertake the analysis of mixtures of known constitution. I venture to state that if the necessary provisions could be made against concoctions chemically prepared, and so as to admit of commercial admixtures only, such as would be likely to be made use of by fraudulent butter factors, there would be no difficulty in getting half-a-dozen or more analysts ready to take up the gauntlet. ARTHUR ANGELL

Southampton, Feb. 7

Large Meteors

A LARGE fireball was seen here this evening at about 7.35 P.M. It rolled slowly across the southern sky, and its path was slightly descending from left to right. The observed part of its course was from γ Orionis to a few degrees below α Ceti. There was no train, but the moon was shining brightly at the time, and may have overpowered any faint appendage of this sort. It was many times brighter than Venus (then near setting), and estimated to equal one-fifth the moon's apparent diameter. The globular form of the nucleus was very evident.

A meteor with very slow motion and a short course was observed on Feb. 2, 8.31 P.M., traversing a space between δ Leonis and Cor Caroli, or just above Coma Berenicis. It was as bright as Mars. Radiant point probably near γ Leonis, and very possibly a member of the same system as the fireball described above, which also appears to have been directed from Leo.

A bright meteor was also seen here on Jan. 31, 9.13 P.M. It fell almost vertically in S.S.W. from the Hyades, and must have been quite equal to Venus. I saw it in a region of the sky covered with thin clouds sufficiently dense to obscure the stars. Radiant point probably just north of α Tauri.

Ashley Down, Bristol, Feb. 5 WILLIAM F. DENNING

The Flame of Common Salt

I SEE that it is sometimes permitted to ask questions in NATURE for information. If I might be allowed to do so, I would ask why common salt gives a *blue* light when cast into a fire of coal, and a *yellow* light when burned on the wick of a spirit lamp? The books I have consulted do not give the reason of this. E. G.

OUR ASTRONOMICAL COLUMN

THE BINARY STAR η CASSIOPEÆ.—Dr. Doberck, of Col. Cooper's Observatory, Markree Castle, has communicated to the Royal Irish Academy the results of a complete discussion of the elements of this binary from the measures to 1875. Though he does not consider the exactness of the orbit to be great, partly owing to the observations being rather unfavourably placed, and partly to uncertainty in the observed distances, the agreement with observation is pretty close, and it appears likely that preference may be given to his elements, over those lately given by Dr. Duner, if the latter are correctly printed. Dr. Doberck's orbit is as follows, being the result of a sixth approximation:—

Peri-astron passage	1909·24
Node	39° 57′
Peri-astron from node	223° 20′
Inclination	53° 50′
Excentricity	0·5763
Semi-axis major	9″·83
Period of revolution	222·435 years.

Combining these values for the semi-axis and length of revolution, with Mr. Otto Struve's parallax (0″·154), we have the following figures:—

Semi-axis major	63·83 earth mean distances.
Mass of system	5·25 sun-masses.

The parallax corresponds to a distance of 1,340,000 times the mean distance of the earth from the sun. The uncertainty attending the measures of distance of the components and the amount of probable error of Mr. O. Struve's value of the parallax, of course allows only of the above figures being regarded as first rough approximations. The semi-axis of the orbit of η Cassiopeæ, it will be seen, results more than twice as great as that of the orbit of Neptune.

The star will doubtless be frequently measured in the present approach to the peri-astron, and every additional five years' observations must be of service in the improvement of the elements.

Dr. Doberck promises an investigation of the orbit of the close binary ω Leonis, no one of the orbits of which star, so far published, represents recent measures. Notwithstanding the case is a troublesome one for calculation, a very fair approximation to the elements should now be practicable.

THE RUGBY (TEMPLE OBSERVATORY) CATALOGUE OF DOUBLE STARS.—Following the excellent plan pursued by Mr. J. Gurney Barclay in the speedy publication of the Leyton measures of double-stars, made by Mr. Talmage with the fine ten-inch refractor of that observatory, Mr. J. M. Wilson and Mr. G. M. Seabroke have given to astronomers (Memoirs, R.A.S., vol. xlii.) a catalogue of micrometrical measures of these objects made at the Temple Observatory of Rugby School during the years 1871-74, with the $8\frac{1}{4}$-inch Alvan Clark refractor, constructed for the late Rev. W. R. Dawes, used by him in his later measures, and now the principal instrument of the Rugby establishment. Working in this interesting branch of astronomy, in co-operation with Mr. E. Crossley's Observatory near Halifax, Rugby has occupied itself upon the even-numbered stars of Struve's Catalogue below 50° N. declination, Mr. Crossley, with Mr. Gledhill, having employed his $9\frac{1}{3}$-inch refractor upon other stars.

The Dawes-refractor is well spoken of by the Rugby

observers in connection with the work in question, and the measures now published not only confirm this favourable opinion of the instrument, but bear inherent testimony to the care and patience expended on the observations, and will doubtless be received as an important and valuable contribution to double-star astronomy, and especially by those who are occupied with similar observations, or the investigation of the orbits of the binary systems. Amongst the more interesting of the revolving stars, the Catalogue has measures of η Cassiopeæ, 36 Andromedæ, α Geminorum, ζ Cancri, ω Leonis (which difficult object was just divided at the end of March 1873), ξ Ursæ Majoris, γ Virginis, ξ Bootis, η Coronæ, Σ 1938, ζ Herculis, 70 Ophiuchi, Σ 3062, &c. The interesting, though difficult binary Σ 518 (Eridani), is probably within the power of such an instrument, but does not appear in the Catalogue; it may be suggested that it is not too late to examine this object in the present season, the actual angle may probably be found very considerably in advance of that obtained by Prof. Winnecke in 1864, and a first approximation to the form of the orbit may soon be practicable.

JUPITER'S SATELLITES.—If we take a mean of the measures of the diameters of the satellites by Struve at Dorpat, and by Engelmann at Leipsic, we shall have for apparent diameters at the mean distance of the primary :—

I. ... 1″·048 II. ... 0″·911 ... III. 1″·513 ... IV. 1″·278

and with a solar parallax of 8″·875, the true diameters in English miles will be :—

I. ... 2,435 ... II. ... 2,115 ... III. 3,515 ... IV. 2,970

The angular diameters at the centre of Jupiter, are :—

I. ... 31′·4 II. ... 17′·1 III. ... 17′·8 IV. ... 8′·6

and the mean distances from the centre of Jupiter :—

I.	266,700 miles
II.	424,300 „
III.	676,800 „
IV.	1,190,400 „

The diameter of the planet's equator is assumed to be 88,200 miles, as lately given in this column.

THE DRAINAGE OF THE ZUYDER ZEE.

THE Dutch are a people who in many respects command the respect of the world. Their little country possesses comparatively few natural resources, and yet they have made so much of it, and they have been compelled to cultivate the virtues of frugality and industry to such an extent, that the people as a whole are probably better off than those of any other country in the world. Small as the country is, it is only by the exercise of great skill and constant watchfulness that they are able to prevent its being overwhelmed by the German Ocean. In this unfortunately they have not always been successful. Over and over again has the sea burst in upon them, laying waste their dearly-loved country, and sweeping away thousands of the inhabitants. It has only been after many severe lessons that they have learned how to keep the invader back. And within recent years they themselves have taken the offensive, and determined to drive out old Neptune from lands which he has possessed for centuries. Even in the seventeenth and eighteenth centuries they succeeded in draining many small areas of land, and during the present century many marshes and lakes have been brought under cultivation, including Lake Haarlem, upwards of 40,000 acres in extent. In this way about 350 square miles of land, mostly devoted to pasture, have been reclaimed, and that entirely by means of windmills.

Now, however, that the applications of steam-power have reached such perfection, this enterprising people have determined upon an enterprise much more gigantic than any they have hitherto attempted,—nothing less than the drainage of the Zuyder Zee. Until the end of the thirteenth century the area now occupied by that arm of the ocean seems to have been mostly dry land, with a lake in the centre, which by means of a river drained into the German Ocean. At the time mentioned, however, in 1282 according to some authorities, the sea broke through what is now the Strait of Helder, and converted the dry land into a gulf.

For many years the drainage of the Zuyder Zee has occupied the attention of the Dutch Government and of engineers, but it is only since the improvements in the application of steam that the idea has been seriously entertained. At last a scheme has been adopted, after many years' careful research and consideration, for the details of which we are indebted to the French journal *L'Explorateur*.

As early as 1865 a Dutch Credit Foncier Association took up the scheme at the suggestion of Mr. Rochussen, an eminent statesman, and employed two engineers, M. Beijerinck, who drained the Haarlem Lake, and M. Stieltjes. These reported on the practicability of draining the southern, the shallowest and most fertile, half of the inland sea. Soundings were made, and numerous specimens of the bottom brought up, and in short a thorough investigation made from a geological and agronomic point of view. The result of these investigations was most favourable, and the specimens submitted to the analysis of a distinguished agricultural chemist, M. van Bemmelen, having been found to consist of alluvial clay or loam of the first quality and of great depth, over an extent of four-fifths of the bottom of the sea, the Society entered into negotiations with the Government. A Government Commission was appointed to consider the whole question from an economic and scientific point of view, and after an investigation lasting about two years, gave in their report in April, 1868. This report was in favour of granting a concession to the Credit Foncier, whenever that company could present a definite plan that would obviate all existing objections. The Society, after further consideration, requested the Government to delegate a commission of specialists to report further on the scheme, taking into consideration all the interests concerned, and to decide upon the plan best adapted to carry the scheme into execution. After three years thorough consideration the Commission gave in a voluminous report in April 1873, which declared that the project from an engineering point of view was practicable; that the clearing of the new lands would be a difficult and very expensive enterprise, but that the experience acquired and the progress of science would furnish the means of overcoming these difficulties, and of making the enterprise a benefit to the country.

The drainage will be effected in that part of the gulf lying between the provinces of Guelderland, Utrecht, and North Holland, over an extent of 195,300 hectares (about 740 square miles, nearly equal to the area of Surrey, and about 100 miles larger than the Dutch province of Zeeland), by means of a principal dike or embankment, of 40 kilometres in length, 50 metres broad at the base, and raised 5 metres above the ordinary tides, to be constructed from the left bank of the mouth of the Yssel to the island of Urk, and from hence to the town of Enkhuyzen in the province of North Holland. The inclosed area will be divided into squares, and numerous pumping steam-engines will then be set to work, having a collective force of 9,400-horse power. The Commission estimates that the work will be entirely accomplished in sixteen years, and that it will cost a sum of 10,000,000*l.* not including the interest of the capital employed; or 1,600,000*l.* for preparatory works, provisional circular canals, &c., about 2,760,000*l.* for the construction of the dike, and the rest for the purchase of engines, the drainage proper, and the construction of reservoirs, internal canals, roads, railway

lines, and works preparatory to bringing the new lands under culture.

The interest on the above sum will raise it to 13,400,000*l.*, but one-fourth of this will be granted as a subsidy by government, which will be amply compensated by the comparatively enormous addition to its small territory.

Of the 473,000 acres to be drained, four-fifths, as we have said, are of great value, composed as they are of a bed of more than a metre thick of the most fertile mud deposited for centuries by the Yssel and other rivers of which the Zuyder Zee is the receptacle. Only one-fifth consists of land of less value and of sands which will be useful in constructing the base of the dike, or to establish large reservoirs, indispensable in all drainage work, for the reception of the waters until they can be conveyed to the sea. Deduction being made for the land absorbed by these works, by canals, dikes, roads, &c. &c., there will remain upwards of 400,000 acres suitable for culture, and the selling value of which ought considerably to exceed the expenses of the enterprise. Every one must wish that this bold and really beneficent scheme may be carried out with complete success.

THE BIRDS OF NORTH-EASTERN AFRICA[1]

BARON THEODOR VON HEUGLIN is well known as one of the most active and successful of the travellers and naturalists of Germany—one who may fairly rank with the Wallaces and Bates of our own country—as regards the extent of his researches. No man living has devoted more time and toil to the investigation of the Fauna of North-eastern Africa, and as regards the classes of birds and mammals, no man living has a better acquaintance with them. Twelve years passed on the coasts and islands of the Red Sea, in the marshes and jungles of the White Nile, and in the Highlands of Abyssinia, during which time constant attention was devoted to the observation and collection of animals have given Herr von Heuglin unrivalled opportunities for amassing this knowledge, to which his skill as an artist has contributed additional facilities. Soon after returning from his last journey in 1865, Herr von Heuglin planned a general work on the Ornithology of North-eastern Africa to embrace all the notes and observations collected during his different excursions, together with the information acquired by the study of specimens from these countries already existing in the continental museums. In 1869, the first part of the present work was issued, but its large extent hindered its progress, and the author was called away to join the German Expeditions to Nova Zembla and the extreme north, to which he was attached as naturalist. It was not, therefore, until the close of last year, or, we believe we may say until the beginning of the present year, that the concluding part of the Ornithology of North-eastern Africa was issued from the press. Completed, it now forms four volumes, illustrated by fifty-one coloured plates and a map of the region of which it treats, and is by far the most perfect work on the subject hitherto published. Prior to the completion of the present work Rüppell's Atlas, and other publications were, so far as regards Nubia and Abyssinia, the only works of reference, whilst of the district of the White Nile so fully explored by Von Heuglin, very little was known except from fragmentary notices. In the present extended work the ornithology of the whole of these countries, together with that of Egypt, the Red Sea, and Northern Somali-land, are treated of together. The sum of species of birds is thus raised to a high figure, no less than 948, of which upwards of 200 are entirely confined to North-eastern Africa. European species are likewise numerous in these countries, Northern Africa being, as is well known, the favoured haunt of our summer migrants during the winter season. Upwards of 300 European birds thus come to be included in Herr von Heuglin's list. The plan of our author's work is good, though it seems to be rather adapted for the home student than for the field-naturalist, neither family nor generic characters being included. But we observe with pleasure that specific diagnoses are given in Latin to all except the best known species, which, after the contumely that certain imperfectly educated naturalists have recently thought fit to bestow upon that classical tongue, is worthy of all praise. The references to former authors are also numerous, and, so far as we have been able to test them, more accurate than is too often, unfortunately, the case in works of this kind. But the great feature of the book are the observations on the habits and localities extracted from the note-books of the unwearied author. These are much more numerous, and better put together than in almost any other work on foreign ornithology with which we are acquainted. Errors and omissions there are no doubt, and must be, in a work of this magnitude, as indeed is sufficiently evident by the many pages of additions and corrections annexed to the fourth volume, but Herr von Heuglin has spared no trouble to bring his Ornithology of North-eastern Africa up to date, and his volumes will long remain a standard work of reference upon the birds of these districts, which are now attracting so much attention in civilised Europe.

P. L. S.

FERTILISATION OF FLOWERS BY INSECTS[1]

XIII.

Additional Alpine Flowers adapted to Cross-fertilisation by Lepidoptera.

THE same relation which I have shown to exist between *Daphne Mezereum* and *striata*, *Primula officinalis* and *villosa*, *Rhinanthus crista-galli* and *alpinus* (NATURE, vol. xi. p. 110), exists also between *Viola tricolor*[2] and *calcarata*, the former inhabiting the plain and the lower mountainous localities, and being adapted to cross-fertilisation by bees; the latter, on the contrary, inhabiting the higher Alpine regions, and being adapted to fertilisation by butterflies.

Viola calcarata is found in the Strela pass towards Davos (2,300 metres above the sea-level), and in the rocky slopes of Piz Umbrail towards Quarta Cantoniera (2,600-2,700 m.) in such plenty as to appear from some distance like a blue carpet of flowers. In the latter locality, July 15, 1875, I saw these flowers assiduously visited by different butterflies, of which I caught two specimens of *Colias phicomone*, and three *Erebia laprona E.* (manto, W. V.) The modifications of structure by which the flowers of *V. calcarata* (Fig. 82-85) differ from those of *V. tricolor* (Fig. 15-22, NATURE, vol. ix., p. 46), besides their eminent conspicuousness, so frequently found in Alpine flowers, are such as prevent Diptera and probably also Apidæ from sucking the honey, whereas butterflies, for which alone the honey is reserved, cannot suck it without effecting cross-fertilisation. For the spur, which generally is only 3-4 mm. long in *V. tricolor*, exceeds in this species 10 mm. in length, its width being only 1 mm. in the vertical, and scarcely half a millimetre in the horizontal direction; and the stigmatic knob, provided with a labiated appendage, as in the large-flowered form of *V. tricolor*, lies so closely pressed against the under lip, that no proboscis of any butterfly can enter the spur without grazing the stigmatic lip. The pollen-grains, when they fall out of the anthers, collect in the hairs which clothe the furrow of the under lip (*po* Fig. 85), and no proboscis of a butterfly can be inserted into the spur without being smeared with pollen-grains, which, in the flower next

[1] Continued from vol. xiii., p. 212.

[2] See H. Müller, "Die Befruchtung der Blumen durch Insecten" Leipzig, 1873, p. 145, and NATURE, vol. ix. p. 44.

visited, will be partly rubbed off on to the lip of the stigmatic cavity (*l* Fig. 85). All the other contrivances of the flower are nearly the same as in the large-flowered form of *V. tricolor*, described in detail in a previous article (NATURE, vol. ix. p. 47).

It may be worth mentioning that in the lower Alpine localities (for instance, near Valcava, 1,500 m., and near St. Gertrud, Sulden, 1,800 to 1,900 m. above the sea-level) I found a variety of *V. tricolor*, which, as well in the conspicuousness of its flowers as with regard to its fertilisers, is intermediate between the large flowered form of *V. tricolor* (NATURE, vol. ix. p. 46, Fig. 15) and *V. calcarata* (Fig. 82). The flowers of this variety, which is called *alpestris*, are 25-30 mm. long, and 18-22 mm. broad; the three lower petals are yellow near their base, as in our *tricolor* and *calcarata*, marked with black streaks converging towards the entrance of the flower; the two upper petals are very variable in colour, white, or bluish, or yellow, with a large bluish margin. The spur is also

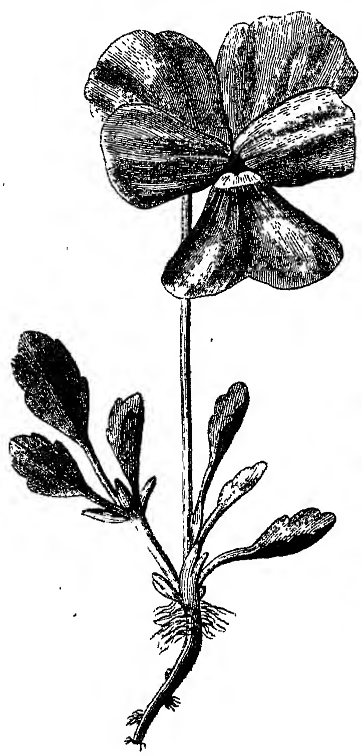

FIG. 82.

FIG 83.

FIG. 82-85.—*Viola calcarata*.[1] FIG. 82.—Whole plant, showing a flower in front, natural size.
FIG. 83.—The same flower, laterally viewed, showing the long slender spur.

variable in length, but on an average remarkably longer than in our *V. tricolor*. I found the flowers of this variety frequently visited by butterflies (*Polyommatus virgaureæ*, L., *P. hippothoë*, L., var. *eurybia*, Ochs., ♂, *Lycaena semiargus*, Rott., *Argynnis pales*, *Hesperia serratulæ*, Ramb.), but only once by a humble bee (*Bombus terrestris*, L., ☿, sucking), whilst our *V. tricolor* is generally visited by *Apidæ*, more rarely by butterflies, and *V. calcarata* exclusively by butterflies. Thus *Viola tricolor*, var. *alpestris* shows us one of the steps by which the common form of this species may have been gradually modified into *V. calcarata*.

[1] *a* anthers; a^1, upper anther; a^2, insertion of the removed lateral stamen; a^3, lower anther; ap^1, appendage of the upper sepal; *b*, beard, *i.e.*, tuft of hairs; *cb*, the lateral surface of the stigmatic knob; c^1, c^3, orange-coloured appendages of the connectives; fi^1, fi^3, filaments; *k*, knob of the stigma; *l*, lip, labiate appendage of the stigmatic opening; *n*, nectary, *i.e.*, honey-secreting appendage of the lower filaments; *ov*, ovary; *p*, petals; p^1, lower, p^2, lateral, p^3, upper petal; *po*, pollen-collecting hairs; *pr*, protective hairs (Sprengel's "Saftdecke"); *s*, sepals; s^1, upper sepal (with the appendage ap^1); s^2, lateral sepal; *sp*. the uppermost part of the spur, containing the honey; *st*. stigmatic cavity; *str*, streaks converging towards the entrance of the flower (Sprengel's "Saftmal"); *sty*, style; *y*, yellow part of the lower petal. (The rest of the corolla is blue.)

Another Alpine flower, remarkable from its conspicuousness and adapted to Lepidoptera, is *Lilium bulbiferum* (Fig. 86-88), which I found on stony slopes of the Schanfick valley, near Chur, in the Spoel Valley, near Zernetz, and, somewhat more frequently, in shelving meadows of the valley of Sulden, beneath the Ortler (1,700-1,800 m. above the sea-level). Although in most points of its structure agreeing with *Lilium Martagon*, described in my article X. (NATURE, vol. xii. p. 50), this flower may be of some interest, because it shows by what slight modifications a sphingophilous species may be adapted to diurnal Lepidoptera, or *vice versâ*. The number and arrangement of the parts of the flower and the structure of the nectary (Figs. 87, 88) are, indeed, the same in *L. bulbiferum* as in *L. Martagon*. That, nevertheless, the latter is cross-fertilised by Sphingidæ, the former by diurnal Lepidoptera, is proved by the following differences:—

1. The flowers of *L. Martagon*, being dark reddish brown, and in the daytime but faintly scented, are only slightly attractive to day-fliers, whilst during the evening

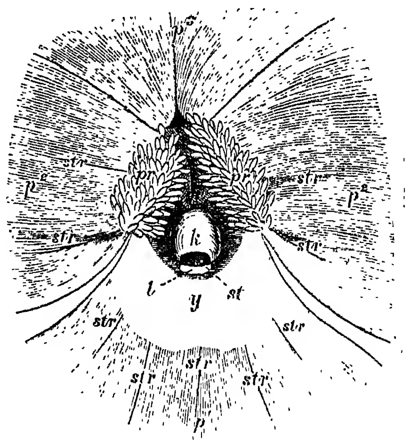

FIG. 84.—Entrance to the flower: seven times natural size.

they emit a very attractive sweet odour. *L. bulbiferum*, on the contrary, by the unusual size of its flowers, with a diameter exceeding 100 mm., and by their colour appearing very splendidly red in the sunshine, is most conspicuous in the daytime, even from a great distance; but being but slightly scented, is incapable of efficaciously attracting night-fliers either by its odour or its colour.

2. The flowers of *L. Martagon* are generally bent downwards, and its sepals and petals reflexed so far as to place the entrances to its nectaries in a nearly horizontal direction, its stamens and pistils projecting downwards, with only their ends slightly bent upwards (Fig. 63, NATURE, vol. xii. p. 50). Thus it affords no landing-place, and offers its honey exclusively to such insects as are capable of inserting a long slender proboscis into the flowers, while they hover in the air by very rapid movements of their wings. *L. bulbiferum*, on the other hand, having its flowers obliquely upright, and offering to their visitors a commodious standing-place on the lowermost petals or sepals, the honey of the lowermost nectaries is accessible to every insect the proboscis of which is long and slender enough to be inserted into the honey-secreting channel.

3. Cross-fertilisation by visiting Sphingidæ is effected in *Lilium Martagon* by the pistil overtopping the anthers, and therefore being first touched by the legs and underside of the visitors, and thus smeared with the pollen of flowers previously visited. In *L. bulbiferum* cross-ferti-

lisation would be prevented if the sepals and petals were as much reflexed as they are in *L. Martagon;* for butterflies would sit down on them and suck the honey out of the channels at their base, without touching the stigma or anthers. But in this species only the ends of the sepals and petals are spread apart, whilst, as far as the sexual organs extend, the leaves of the perianth diverge but so slightly that a butterfly, when inserting its proboscis into the nectary, can scarcely avoid touching the stigma and anthers; and, the pistil being situated nearest to the

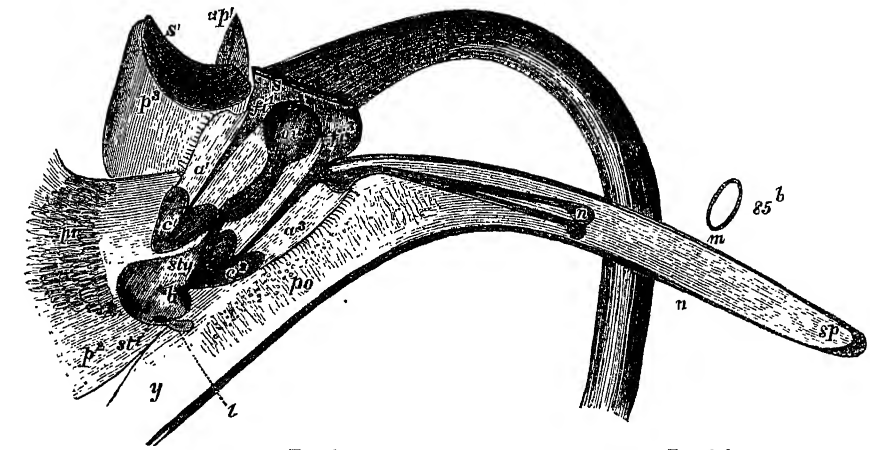

FIG 85. FIG. 85*b*.

FIG. 85.—Lateral view of the flower after the half of its sepals and petals and one of the two lateral anthers have been removed and the underlip somewhat depressed: seven times natural size. FIG. 85*b*.—Transverse section of the spur, behind the line *m n*, Fig. 85.

lowermost petals and sepals on which the butterflies alight and suck, the stigma here also will be commonly first touched and thus fertilised by pollen-grains of flowers previously visited.

Although, by the contrivances now described *Lilium bulbiferum*, from its very conspicuous flowers, is very likely to be cross-fertilised by butterflies in sunny weather, still in rainy periods many flowers may wither without having received any visit from a butterfly. Hence the possibility of self-fertilisation appears to be indispensable both to *L. bulbiferum* and to *L. Martagon*. In both the anthers and stigma are simultaneously developed to maturity, and are often found in contact with each other; and self-fertilisation may thus be effected in case cross-fertilisation by visiting Lepidoptera is wanting.

4. Direct observation of the visitors proves that *L. Martagon* is really fertilised by Sphingidæ, for instance by *Macroglossa stellatarum*, as observed by myself (see NATURE, vol. xii. p. 50), and by *Sphinx euphorbiæ*, as observed by Federico Delpino;[1] and that *L. bulbiferum* is really fertilised by butterflies, for instance by *Polyommatus virgaureæ*, L., *P. hippothoë*, L., var. *eurybia*, Ochs.,

FIG. 86-88.—*Lilium bulbiferum*. FIG. 86.—Lateral view of the flower after the half of the perianth has been removed; natural size. *a*, anthers; *st*, stigma; *n*, nectary.

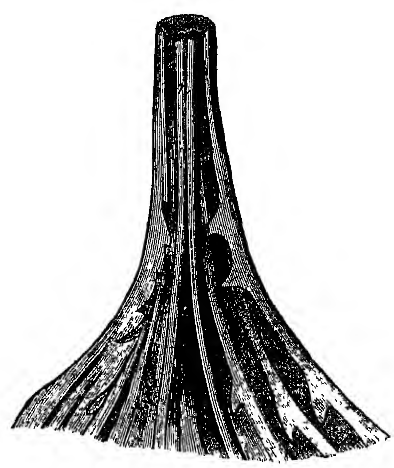

FIG. 87.—Basal portion of one of the leaves of the perianth. *e*, entrance into the nectary; *n*, nectary: magnified twice.

and *Argynnis aglaia*, L., all of which (July 20, 1875) I found repeatedly in the flowers, not only sucking the honey, but also resting, displaying their wings in the sunshine, and sometimes a male of *Palyommatus virgaureæ*, L., sitting by the side of a female of the same species.

It is a striking fact that all these species of butterflies are of nearly the same splendidly red colour as the flowers they visit. I do not know whether this fondness has been effected by natural selection, agreement of colour

[1] Written to me in a letter of May 1875.

with the flower they sit upon making the butterflies invisible to their pursuers, or if merely the same predilection for a certain colour which has ruled the sexual selection of these butterflies, and by this influenced the colour of their wings, impels them also preferably to visit flowers of their favourite colour; but, from many analogous observations to be published on another occasion, I am strongly inclined to believe that the agreement of colour between the flowers of *L. bulbiferum* and their visitors is not a merely fortuitous one.

Most of the differences between the flowers of *L. Martagon* and *bulbiferum* may be intelligible from the pre-

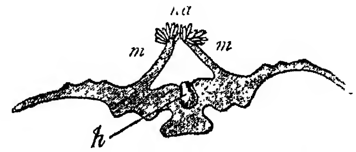

FIG. 68.—Transverse section through the base of one of the leaves of the perianth; seven times natural size. *h*, honey filling up the furrow from which it is secreted; *m*, margins covering the furrow; *ha*, hairs closing the slit between these margins.

ceding explanation;—still the question remains: What intermediate contrivances are imaginable by which the transformation of a sphingophilous species of Lilium into another one adapted to butterflies could be effected? In this respect it is remarkable that the flowers of *L. Martagon* are not always bent downwards, but sometimes have their axis in a horizontal or somewhat upright position, and that such flowers are now and then also fertilised by day-fliers. Thus, July 19, 1874, near Franzenshöh, I saw a specimen of *Zygæna transalpina*, Esp., visiting the flowers of *L. Martagon*, and inserting its proboscis into the honey-secreting channels; and likewise, July 20, 1875, near St. Gertrud, in the valley of Sulden, a specimen of *Polyommatus hippothoë*, var. *eurybia*, Ochs., behaving in the same manner. HERMANN MÜLLER

SCHOLARSHIPS AND EXAMINATIONS FOR NATURAL SCIENCE AT CAMBRIDGE, 1876.

THE following is a list of the Scholarships and Exhibitions for proficiency in Natural Science to be offered at the several Colleges and for Non-Collegiate Students in Cambridge during the present year:—

Trinity College.—One or more Foundation Scholarships of 100*l.* and one Exhibition of 50*l.* The examination for these will commence on April 18. The Scholarships are open to undergraduates of Trinity College, and persons under twenty who are not yet resident members of the University. The Exhibition is open to persons under twenty, who have not yet commenced residence at the University.

St. John's College.—One of the value of 50*l.* per annum. The examination (in Chemistry, Physics, and Physiology, with Geology, Comparative Anatomy, or Botany) will commence on April 22, and will be open to all persons who have not commenced residence at the University, as well as to all who have entered and have not completed one term of residence. No candidate will be examined in more than three of the above subjects. There is a separate examination in Natural Science at the time of the annual College examination at the end of the academical year, in May; and Exhibitions and Foundation Scholarships will be awarded to students who show an amount of knowledge equivalent to that which in Classics or Mathematics usually gains an Exhibition or Scholarship in the College. In short, Natural Science is on the same footing with Classics and Mathematics, both as regards teaching and rewards.

Christ's College.—One or more in value from 30*l.* to 70*l.*, according to the number and merits of the candidates, tenable for three and a half years, and for three years longer by those who reside during that period at the College. The examination will be on April 4, and will be open to anyone, whether a member of the College or not—provided his name is not on the boards of any other College in the University—who is not of sufficient standing to be admitted *ad titulum Baccalaurei in Artibus.* The candidates may select their own subjects for examination. There are other Exhibitions which are distributed annually among the most deserving students of the College.

Gonville and Caius College.—One of the value of 60*l.* per annum. The examination will be on April 4, in Chemistry and Physics, and Zoology with Comparative Anatomy and Physiology; it will be open to students who intend to commence residence in October, and are under twenty. Further information may be obtained from the Tutors.—Scholarships of the value of 20*l.* each or more are offered annually for Anatomy and Physiology to members of the College.

There will be an examination on the 4th of April, 1876, in Botany and Comparative Anatomy in its most general sense (including Zootomy and Comparative Physiology), for two *Shuttleworth Scholarships*, each of the value of 60*l.* per annum, and tenable for three years. The candidates must be registered medical students of the University who have kept eight terms, have passed the Additional Examination required for Candidates for Honours, and produce satisfactory testimonials of good conduct. A successful candidate, if not a member of Gonville and Caius College, must become a member of the same. They are tenable with any other Scholarship at the College.

Gentlemen elected to the *Tancred Medical Studentships* are required to enter at this College; these Studentships are five in number, and the annual value of each is 100*l.* Information respecting these may be obtained from B. J. L. Frere, Esq., 28, Lincoln's Inn Fields, London.

Clare College.—One of the value of 60*l.* per annum, tenable for two years at least. The examination (in Chemistry, Chemical Physics, Zoology with Comparative Anatomy and Physiology, Botany with Vegetable Anatomy and Physiology, and Geology) will be on March 28th, and will be open to students intending to begin residence in October.

Downing College.—One or more of the value of 60*l.* per annum. The examination (in Chemistry, Comparative Anatomy and Physiology) will be on, or about, April 25, and will be open to all students not members of the University, as well as to all undergraduates in their first term.

Sidney College.—One of the value of 60*l.* The examination will be on April 4, and will be open to all students who intend to commence residence in October.

Emmanuel College.—One of the value of 70*l.* The examination on April 4, in Botany, Chemistry, Chemical Physics, Geology and Mineralogy, Zoology, Comparative Anatomy and Physiology, will be open to students who have not commenced residence.

Non-Collegiate Students.—An Exhibition each year is given by the Clothworkers Company, value 50*l.* per annum, tenable for three years. Examination about Christmas, open to non-collegiate students who have commenced residence in the October term, and to any who have not commenced residence. Information to be obtained from the Rev. R. B. Somerset, Cambridge.

Although several subjects for examination are in each instance given, this is rather to afford the option of one or more to the candidates than to induce them to present a superficial knowledge of several.

Candidates, especially those who are not members of the University, will, in most instances, be required to show a fair knowledge of Classics and Mathematics, such, for example, as would enable them to pass the previous examination.

There is no restriction on the ground of religious denominations in the case of these or any of the Scholarships or Exhibitions in the Colleges or in the University.

Further information may be obtained from the Tutors of the respective Colleges, and the names, with certificates of character, date of birth, &c., must be sent to the Tutor of the College, in each case, several days before the examination.

Some of the Colleges do not restrict themselves to the number of Scholarships here mentioned, but will give additional Scholarships if candidates of superior merit present themselves; and other Colleges than those here mentioned, though they do not offer Scholarships, are in the habit of rewarding deserving students of Natural Science.

It may be added that Trinity College will give a Fellowship for Natural Science, once, at least, in three years; and that most of the colleges are understood to be willing to award Fellowships for merit in Natural Science equivalent to that for which they are in the habit of giving them for Classics and Mathematics.

THE INDUSTRIAL APPLICATIONS OF OXYGEN[1]

LAVOISIER, who was the first to recognise in its widest range the importance of oxygen, was also the first who succeeded in making a practical use of it. "It is evident," he writes,[2] "that atmospheric air is not the best calculated means to increase the effect of fire; for, when a volume of air is conveyed through the bellows to red-hot coals, three (?) parts of noxious or at least useless gas are conveyed with every one part of the useful kind of air; consequently, if the latter could be employed for combustion in its pure state, the action of the fire would be greatly increased. Doubtless this idea has occurred to many others before me; indeed, I hear that M. Achard[3] has already tried the experiment, but as yet a cheap and convenient apparatus is wanting." Lavoisier first used the bladders of animals, which were provided with cocks and tubes. "Then," continued he, "I made a hole with a knife from three to four lines deep in a large piece of charcoal and placed in it six grs. of platinum. I then ignited the charcoal through the blowpipe communicating with the enamel lamp, uncocked my apparatus, and blew the pure vital air into the cavity. The coal burnt very rapidly with detonation (such as is produced by fusing saltpetre) and with dazzling brightness; in a few moments the platinum was fused to grains, which soon united into a drop. The fusion was effected equally well when using commercial platinum as when using that, which had been deprived of its magnetic parts by the magnet. Hitherto, it is well known, platinum had been considered infusible." In the course of the same year Lavoisier[4] improved his apparatus with the assistance of Meusnier, and soon became possessed of a gasometer consisting of two boxes greatly resembling, on a small scale, the well-known reservoirs used in gasworks for holding coal-gas. About the same time Saron had constructed two blow-pipes (*chalumeaux*), one to furnish oxygen, and the other hydrogen gas.

By their help Lavoisier did not succeed in melting platinum.[5] However, at that time he and Saron had conceived the idea of constructing an improved blow-pipe, in which the oxygen should surround the hydrogen, and this led to the contrivance of the oxyhydrogen blow-pipe, which has ever since been of such substantial service in the working of platinum and the soldering of lead.

No further attempts were made to fuse platinum by means of oxygen until Deville and Debray[6] in 1857-1859 and the years following, published their excellent researches "On the platinum metals," and brought the fusion of platinum into practice. The soldering of platinum with platinum, and the manufacturing of cast bars, were carried on on a large scale, first by Messrs. Johnson, Matthey, and Co., in London, and afterwards, though on a smaller scale, by Heræus in Hanau. The experiments of Debray and Deville were attended with one especial result, the discovery of a fire-proof material for making furnaces and crucibles. This is quick-lime, which had the further advantage of retaining the heat as completely as possible. Besides, the temperature was increased by conducting the flame from above, directly, to the surface of the metal, and regulating the quantity of oxygen and hydrogen as theory and practice suggested it. To melt 2 kilogs. of platinum, theory demands 55 litres oxygen and 110 litres hydrogen, while in reality more than one kilog. is fused by these quantities, so that not 50 per cent. of the generated heat is lost (a very satisfactory result). Their experiments were of still greater importance for the history of oxygen industry, inasmuch as they gave occasion for comparing the prices of different modes of preparing it, and stimulated inquiry after cheaper processes. These we may divide into chemical and mechanical, subdividing the former again into continuous and intermittent processes. Up to this time the following modes of preparation were in use, or had been proposed. To begin with the oldest method of Priestley, heating oxide of mercury, unquestionably the most costly and the least adapted for practical purposes; then Scheele's method, treating peroxide of manganese with sulphuric acid, which produces sulphate of manganese and oxygen. Through Berthier's researches in 1822, this process has been superseded for manufacturing purposes by heating peroxide of manganese; and, lastly, we have to mention Bertholet's method, the heating of chlorate of potassium. Notwithstanding its cost, the latter is constantly used in the laboratory, because it is easy and requires little heat, although it not unfrequently happens that a too rapid fusion causes explosions. To obviate this inconvenience, the suggestion has repeatedly been made of mixing peroxide of manganese with the chlorate of potassium.

More recent accidents, especially a fearful explosion which took place in a pharmaceutical laboratory in Paris, induced Debray and Bourgoin[1] to publish the precautions taken in Deville's laboratory: peroxide of manganese, or what is easier to obtain in a pure state, red oxide, Mn_3O_4, is added to the chlorate of potassium in equal quantities, and the iron vessel containing it exposed to heat in a charcoal furnace, so that the fire is lighted from above. Schwartz[2] also gives an account of some accidents occasioned by using peroxide of manganese adulterated with lampblack, and by inadvertence, even with sulphuret of antimony; and for that reason he recommends that all mixtures for the production of oxygen be first tried by heating them on a sheet of platinum. Munck[3] proposed adding oxide of iron, which is more easily recognised, instead of peroxide of manganese. Scheele's method of using peroxide of manganese and sulphuric acid had this disadvantage: the glass vessels employed were very liable to burst, through the solidifying of the sulphate of manganese. To prevent this, R. Wagner[4] proposed to substitute bisulphate of sodium for sulphuric acid, thus forming an easily fusible double salt, which would afford no danger of breaking the retort when cooling. Pure peroxide of manganese yields 18 per cent. by this treatment, while heating it to red heat, which resolves it into sesquioxide, yields only 12 per cent. of oxygen; nevertheless, the last method is the cheapest. Deville and Debray[5] calculates its expense in proportion to the prices of peroxide of manganese, which are as follows:—

	Per 100 kilogs.	Per 1 cb.m.
Romanèche	10 francs	4·86 francs
Spain	16 „	3·45 „
Pyrenees	18 „	3·85 „
Giessen	29 „	4·87 „
Italy	40 „	5·98 „

The trifling value of the remaining sesquioxide, which (containing iron) is of no use in the manufacture of glass, is not here considered.

The calculation dates from the time when the regeneration of peroxide of manganese was an unsolved problem. Allowing therefore the price of oxygen obtained from peroxide of manganese to vary between 3·45 and 5·98 fr., it is more than twice as cheap as that which is procured from chlorate of potassium, for which, according to Dupré,[6] the average price is 10 fr.

As a much cheaper source, Deville and Debray now had recourse to sulphuric acid, which at a high temperature is decomposed into water, sulphurous anhydride, and oxygen.[7] Retorts of hard glass of a capacity of 5 litres are filled partly with thin layers of platinum-foil or bits of tile and heated to a red heat, whilst a thin stream of sulphuric acid is introduced.

The escaping gases pass through a cooling contrivance to condense the sulphuric acid, and afterwards through water to remove the sulphurous acid gas. Thus, out of 2·435 kilogs. of sulphuric acid of spec. grav. 1·827, 240 litres of oxygen were obtained, and the price was calculated at 1 fr. per cb.m. By

2 "Mémoire sur un moyen d'augmenter considérablement l'action du feu et de la chaleur dans les opérations chimiques" (1782). Œuvres de Lavoisier, ii., 425.

3 The above-mentioned work of Achard is to be found in the Memoirs of the Berlin Academy of 1779, under the title, "Sur un nouveau moyen de produire avec une très-petite quantité de charbons une chaleur égale a celle qu'on peut produire par des verres et des miroirs ardents d'une grandeur considérable." Achard decomposed saltpetre by heat in an earthenware retort, and introduced the "dephlogisticated air" thus obtained into a pair of bellows, from whence it was conveyed into a charcoal furnace, where some iron nails in a hessian crucible were rapidly reduced to fusion. He was also of opinion that the introduction into badly ventilated rooms of gas procured in this way would cause the air in the same to be "dephlogisticated."

this process the cost of melting 1 kilog. of platinum was reduced to 20 or 30 centimes. According to a notice of Moigno,[1] the firm of José de Susini and Co., in Paris, in the year 1867 prepared oxygen in this way at the low price of 0·85 fr. per cb.m., retransforming sulphurous into sulphuric acid. Instead of the acid itself, Deville and Debray also proposed employing sulphate of zinc: 100 kg. of anhydrous salt yielded them 6·8 cb.m. of oxygen (far more therefore than the best peroxide of manganese), 22 kilogs. of sulphurous acid gas, and 51 kilogs. of oxide of zinc.

Wagner's statement[2] is worthy of remark, that in the year 1867 neither of these methods was in use in Deville's own laboratory; perhaps because the sulphurous acid evolved complicated the working.

We must not pass over Archereau's attempt[3] to employ sulphuric acid in its cheapest combination as gypsum. He asserted that heating pulverised gypsum with sand would produce silicate of calcium, setting sulphurous acid free, which he partly condensed (as did also Susini) under a pressure of three atmospheres, and partly removed by means of a thin paste of lime. A manufactory established on these principles in Paris did not work long.[4] Obviously the very high temperature required is an obstacle. The production of this gas from one of the oldest of all oxidising agents, saltpetre, was not employed on account of two drawbacks. In the first place, a quantity of nitrogen is mixed with it; and secondly, the temperature necessary for its decomposition greatly increases the cost. This last inconvenience was remedied by Webster's[5] adding oxide of zinc to saltpetre: 20 lbs. of nitrate of soda and 4 lbs. of crude oxide of zinc furnished 94·676 cubic feet of a mixture of 59 p. c. of oxygen and 41 p. c. of nitrogen, while chiefly oxide of zinc and caustic soda remained. The price of the oxygen contained in this mixture, so useful for many purposes, without taking into consideration the value of the solid residue, amounts[6] to 2·32; and allowing for the value of the remains, the price is reduced to 0·78 fr.

In no one of these methods appears one of the leading ideas of modern industry, viz., the regeneration of the residues.

The following plans were happier in this respect, and thereby, in part, more successful.

To combine chemically the oxygen of the air with a carrier of oxygen that would easily give off the gas, and would be always ready to take up and again to give off fresh quantities of oxygen, just as mercury does when we transform it into its oxide and retransform the oxide into the metallic state—that is the problem of which the last few years have given an economical solution. As early as 1829 Dingler jun.[7] discovered that oxide of copper as well as peroxide of cobalt and nickel, treated with an excess of chloride of lime, generate oxygen gas, thereby transforming it into chloride of calcium. In the year 1845 Mitscherlich[8] observed that many other metallic oxides, viz. peroxide of manganese, hydrate of ferric oxide, cupric oxide, &c., when added to a solution of chloride of lime, caused a development of pure oxygen. In 1865, Th. Fleitman[9] renewed these observations with reference to freshly prepared sesquioxide of cobalt, the smallest trace of which was sufficient completely to reduce a concentrated solution of chloride of lime into chloride of calcium and oxygen. For practical purposes he recommended to heat to 70° or 80° a highly concentrated solution of chloride of lime (which to avoid frothing over should be previously cleared by filtration) with 0·1 to 0·5 per cent. of sesquioxide of cobalt. By applying chloride of lime containing 35 per cent. of pure hypochlorite, he obtained from twenty to thirty volumes of oxygen in a regular stream; and other observers, notably F. Varrentrapp,[10] confirmed these results, and commended their industrial application. The sesquioxide of cobalt need not be added ready formed; any cobalt salt answers the same purpose, and the sesquioxide employed with or formed by it soon settles at the bottom and can be used again and again.

For that very reason a cheaper oxide—cupric oxide, for instance, as Böttger[11] proposed—would be of trifling advantage, because its use demands[12] a much higher temperature for decomposition. The tedious work of preparing a clear solution of chloride of lime may be avoided by adding[1] small morsels of paraffin, a thin layer of oil on the surface preventing an overflow. There was still one evil to be grappled with. Chloride of lime requires considerable quantities of water for its solution, and consequently large vessels were necessary for the production of even a moderate quantity of oxygen. For that reason a Winkler[2] rejected chloride of lime, preferring to pass chlorine through a thin paste of lime mixed with a little nitrate of cobalt. By this modification a greater quantity of oxygen can be produced in the same vessel, and there is no danger of the liquid frothing over. The part which the metallic oxide plays in these methods is easy to understand. It acts as a carrier of oxygen, passing by turns into a higher and very unstable oxide, and being reproduced in its original state. The hypochlorous acid transforms sesquioxide of cobalt into cobaltic acid, which instantly separates again into oxygen and sesquioxide of cobalt.

$$Co_2O_3 + 3\,[CaCl(OCl)] = 3CaCl_2 + 2CoO_3$$
$$2CoO_3 = Co_2O_3 + O_3.$$

Thus, part of our problem is solved. By the production of oxygen the carrier of oxygen is reproduced. The oxygen, however, thus obtained is not taken from the atmosphere, but from lime. The solution of chloride of calcium resulting from its preparation must be removed and replaced by fresh lime water. The process is therefore an interrupted one, and in this respect capable of economical improvements. These also have been accomplished by methods which carry us back from the wet to the dry way.

Since 1851[3] Boussingault proposed baryta as a carrier of oxygen, which, heated to redness in a porcelain tube and treated with moist air previously freed from carbonic acid, became transformed into peroxide of barium. A current of steam passing over it reproduces hydrate of barium and liberates the oxygen; while an admixture of lime or magnesia prevents the fusing together of the mass, and thus 75 gr. of baryta yield 4 to 5 lit. of oxygen at every operation.

In 1868 Gondolo[4] improved on this method by employing iron tubes protected by an outside covering of asbestos and by an inside layer of magnesia, and placed in suitable furnaces, the temperature of which could be easily regulated. He further added to the baryta a little manganate of potassium as well as lime and magnesia. In this manner 122 alternate oxidations and reductions were carried on in the same tube. Whether it be the high temperature or other obstacles which have prevented this method from being generally adopted, it has certainly made no way as yet into practice, although it has paved the way to final success.[5] Looking for carriers of oxygen of a more useful sort than baryta, the chlorides of copper were the first to strike the attention of chemists. The facility with which they pass into oxychlorides of various compositions when exposed to the air, is the base of the manufacture of a well-known painter's colour, Brunswick green. In 1855 Vogel proposed the action of muriatic acid on cupric oxychlorides as a means of obtaining chlorine.[6] Mallet[7] studied these substances more closely, and founded on them a process of obtaining both chlorine and oxygen. He discovered that cupric chloride, treated with a current of steam, changes at 100° to 200° into several oxychlorides, which, by means of muriatic acid, are not only at once retransformed into the chloride and free chlorine gas, but give off all oxygen at a temperature of only 400°, 1 kilog. of cupric chloride yielding from 28 to 30 lit. of oxygen. Experiments on a large scale produced from 3 to 3½ cb.m. of oxygen, or from 6 to 7 cb.m. of chlorine, from 100 kilogs. of chloride of copper in one operation. As four or five operations can be performed in one day, from 200 kilogs. of cupric oxychloride 15 to 18 cb.m. of oxygen are producible daily.

The apparatus employed consists of revolving retorts of cast-iron lined with clay, and containing the cupric chloride mixed with ⅓ of sand or kaolin to render the mass less fusible. This

5 Robbin (Pogg. Ann., cxxii, 256) employed peroxide of barium in another form for laboratory use. He recommends a mixture of chromate of potassium (1 mol.) and peroxide of barium (3 mol.) with dilute sulphuric acid, to obtain a very regular and abundant supply of oxygen:—

$$2CrO_3 + 3H_2O_2 = Cr_2O_3 + 3H_2O + 6O.$$

method was employed at Cologne in 1871.[1] A company formed in Paris for its employment had but a very brief existence,[2] probably owing to a similar discovery which soon supplanted the one described above.

This method, originated and perfected since 1867,[3] by the inventive powers of M. Tessié du Motay, employs peroxide of manganese as the carrier of oxygen, and takes its stand upon the following reactions. Sodic hydrate exposed to dark red heat with manganese and air, yields, as Mitscherlich discovered, manganate of sodium and water, $4NaOH + 2MnO_2 + 2O = 2\ Na_2MnO_4 + 2H_2O$; and manganate of sodium, under the influence of a dry current of overheated steam, disengages at the same temperature sodic hydrate, manganic sesquioxide, and free oxygen, $2Na_2MnO_4 + 2H_2O = 4NaOH + Mn_2O_3 + 3O$. By previously depriving the overheated air of its carbonic acid, one may preserve the mixture in a perpetually active state. This method has been thoroughly tested and approved, and has since been employed on a large scale in Comines, near Lille; in Pantin, near Paris; in New York, in Brussels, and in Vienna. Bothe[4] informs us that a mixture of sixty parts of dry carbonate of sodium with forty parts of 95 per cent. peroxide of manganese, when fused, contains 74·62 parts of manganate of sodium, and that 40 kilogs. of this mixture, which, according to calculation, should give 2,036 cb.m. of oxygen gas, produced in reality 1,800 cb.m., or 90 per cent. of the theoretical yield. He recommends the proceeding as a very practical one. M. Pourcel[5] has given us the most detailed description. According to him, M. Tessié du Motay employs cast-iron ellipsoidal retorts, which lie horizontally one beside the other, and are divided by a grating parallel to their axes, into two unequal parts. Over the grating 350 kilogs. of manganate of sodium, or of the reduced mixture of manganese and soda, are so spread out that its height amounts to 0·60 m., and the empty space above and below the mass is as inconsiderable as possible. In Comines, where five of these retorts are used, the amount of oxygen produced daily is 140 cb.m. at the cost of 450 kilogs. of coals for heating the retorts, and of 150 kilogs. used for the steam-engine. The air is passed through a thin iron vessel with quick-lime by means of the bellows, under a pressure of from 3 to 4 cm. of mercury, and enters the retort from above. The temperature of the latter can be observed through a hole provided with an iron stopper. In this way the air gives off only about half of its oxygen, so that to produce 1 vol. of oxygen 10 vol. of air must be passed through, the remainder escaping into the atmosphere. Five minutes suffice for oxidising the reduced mass. The current of air is then interrupted by means of a three-way stopcock and superheated steam passed through the retorts for five minutes, while the gas, passing out below the grating, enters condensers. Here a fine rain of cold water frees the oxygen from the steam, and the gas enters the gasometer under the pressure of a column of water of from 8 to 10 cm. in height. Thus reduction and oxidation alternate at intervals of five minutes. After a lapse of six hours only, it is necessary, for a perfect regeneration of the fused mass, to admit atmospheric air for about an hour, because the quantity of oxygen obtained becomes lowered after five or six hours, down to half or even a third part of the original quantity. In Vienna the cocks are worked by an automatic apparatus. The longer the steam is forced in and the retorts freed from air before the communication with the gasometer is opened, the purer will be the oxygen; half a minute is enough to leave only 15 per cent. of nitrogen mixed with it, provided the injurious space in the retort be kept as small as possible. If the nitrogen be lowered to 4 per cent., which is easily effected, the sacrifice of oxygen will be so much the greater. To make certain that the quantity of nitrogen remains within the limits of 15 and 10 per cent., which are proved to be the most practicable, gas is taken from the gasometer or the condenser in graduated tubes, and the oxygen is absorbed by means of pyrogallate of potassium, a reaction attended by quick and sure results, even in unpractised hands.

As every cooling down of the retort below dark red heat lessens the yield, care is necessary to raise the temperature of the air, as well as of the steam, to about 300° C. In Pantin, where several groups of ten retorts are set up, two of them are filled with pumice-stone to warm the air and the steam. The composition of the fused mass corresponds to 2 mol. NaOH, 1 mol. MnO_2, and the fifth part of a mol. of cupric oxide, which serves only to disintegrate the mass and make it more accessible to the influence of the air and steam. In Comines peroxide of manganese is reproduced from the residues of chlorine by the known methods, almost in a pure state. Its market-price, for which the Pantin works buy it, amounts to 2 fr. per kilog. The high price of this basis of the manufacture of oxygen is indifferent, as it can be used continuously, and the longer, the more carefully the air is kept free from carbonic acid. If, through some unavoidable interruption of the manufactory, the mass should have attracted carbonic acid from the atmosphere, it suffices to bring it to a red heat, and pass steam over it until the steam, on leaving the retorts, produces no precipitates in lime-water: then hot air passed over it will restore the mass to its original efficiency. On an average, a retort is said to last about a year.

M. Tessié du Motay's method produces a cubic metre of 90 per cent. of oxgyen for 15 to 30 centimes,[1] or, according to the results of Herr Kuppelwieser's experiments,[2] 1,000 cubic feet at 3 fr., a price in accordance with the last-mentioned sum, and scarcely exceeding that of coal-gas. We may regard this method as a final and successful solution of the problem of discovering economical and rational chemical means for obtaining oxygen.

NOTES

The Wollaston Medal of the Geological Society has been awarded to Prof. Huxley, and will be presented at the Anniversary of the Society on the 18th inst. Prof. Huxley has also been elected a Corresponding Member of the Danish Academy of Sciences.

The *Times* of yesterday contains a summary account of what has been done so far in this and foreign countries towards organising the Loan Collection of Scientific Instruments to be opened at South Kensington in April. The invitation from the Science and Art Department has met with a hearty response both in this country and from foreign Governments. We last week gave a list of the Foreign Committees, and the *Times* publishes the list of those on the English Committees in the various departments of Mechanics, Physics, Chemistry, Geology, and Biology; and as the *Times* remarks: "By going over them not only does one get an idea of the disinterested way in which men—for the most part busy men—have come forward to help the Department, but there can be no better guarantee of the success of the Exhibition than that afforded by the list of those who are labouring to make it successful." It would indeed be difficult to mention any man of scientific eminence in this country whose name is not included in the list. Out of England, as our readers would see from last week's list, the most numerous committee is the German one. On this the *Times* says:—"The German list gives us much food for thought. It is known, for instance, that the thirty-four local committees, representing her many Universities, Polytechnic Schools, and other scientific centres, were all organised in a week, and that her Universities will, in all probability, be the richest contributors, whereas when we have mentioned Edinburgh, Glasgow, Manchester, Birmingham, Leeds, and Liverpool, and perhaps Newcastle, we have almost exhausted the localities where committees would be useful." The teaching side of the collection will be complete beyond all anticipation. The Physical Cabinet, it is stated, will be such as the world has never seen, towards the formation of which not only will British, French, German, Italian, and Austrian instrument makers lend their aid, but the collections of the Royal Institution, Glasgow University, Edinburgh University, King's College, the Conservatoire des Arts et Métiers, the Collège de France, the Universities of Berlin, Bonn, Heidelberg, Leipsic, Vienna, Rome, and Leyden, and the Tayler Institution at Haarlem, and the like, will be ransacked. The Chemical and Historical Collections will be of scarcely less magnitude. With regard to the last it is still doubtful whether Italy will part with Galileo's telescope and magnet, even for a month, though it is

hoped that some of the numerous instruments left behind by Torricelli, Volta, and Galvani, may yet be obtained. Besides instruments which are sacred as having belonged to the pioneers of science, others with which the greatest investigators of modern times have made their famous discoveries will have their place in the Exhibition. The *Times* article concludes :—"The scientific position of England has been distinctly raised by this step on the part of our Government, and the Lord President is to be congratulated on a step which not only adds reputation to his Department, but promises to aid so greatly the cause of scientific instruction throughout the land."

UNDER the direction of Prof. Todaro, the biological department in the University of Rome has recently been exhibiting great activity. Prof. Todaro himself has published during the last two or three years a number of important papers, including a monograph upon the development of Salpa. There has also appeared a volume entitled "Recerche nel Laboratorio de Anatomia della Universita de Roma," which contains a number of valuable contributions both by Prof. Todaro and his pupils. Considering the vigour which is being displayed by the anatomists at Rome, it is much to be regretted that the University of the capital of Italy supplies, for biological purposes, accommodation of the most meagre kind.

MR. HERBERT SPENCER has been elected a Corresponding Fellow of the Royal Academy of Rome.

THE first and second Cambridge Smith's Mathematical Prizes have been awarded respectively to Mr. J. T. Ward and Mr. W. L. Mollison, the Senior and Second Wrangler.

AT the last sitting of the Lisbon Royal Academy of Science, the members passed a resolution expressing their appreciation of Lieut. Cameron's labours in traversing the African continent from east to west. A copy of this resolution will be transmitted to Lieut. Cameron. At the same sitting Mr. Bowdler Sharp and Father Secchi were elected Corresponding Associates of the Academy.

ON Monday next, Feb. 14, Prof. Flower will commence an important course of nine Hunterian Lectures at the Royal College of Surgeons, Lincoln's Inn, to be given on Mondays, Wednesdays, and Fridays, upon "The Relation of Extinct to Existing Mammalia, with special reference to the Derivative Hypothesis." This course is a continuation of that of 1873, which we were enabled to report shortly at the time. The discoveries since that year among the *Monotremata, Edentata, and Ungulata* will be described, as well as the American extinct Perissodactylates and Arteodactylates. Among the most interesting features of the course will be the account of the extinct aberrant Ungulate, *Uintatherium*, and the quasi-proboscidians of North America, also of *Toxodon* and *Nesodon*. The fossil Sirenia, including *Halitherium*; the Cetacea, Pinniped Carnivora, Fissiped Carnivora; Tillodontia, Insectivora and Cheiroptera, Rodentia and Primates will also be included. The lectures will be fully illustrated by specimens from the Museum, and by diagrams. We shall have the opportunity of giving fairly full abstracts of these lectures, one each week—the first in our next issue.

M. CAZIN sends an interesting note to the last number of the *Bulletin International*. It seems that M. G. Loppé, the glacier painter, well known to all Alpine tourists, and Mr. James Eccles, of London, attempted on January 20 last the ascent of Mont Blanc. They were only able to reach the Grand Plateau; the wind raised thick clouds of snow dust, which threatened to bury the party. Thermometric observations were made, and they show that the temperature varies little in the high Alpine regions. The lowest temperature (− 13°) observed on the Grand Plateau (3,932 metres) is no lower than the temperatures observed in the same place during summer. The provisions—meat, bread, wine, tea—were frozen, and the wind made the cold insupportable. The following are the temperatures observed during the ascent and at Chamounix :—

ON THE MOUNTAIN.

Jan.	19.	Junction of the glaciers,	2,600	metres,	4.30	P.M.	− 5°·5
,,	,,	Grand Mulets ...	3,050	,,	8.30	,,	− 7
,,	20	,, ,, ...	,,	,,	2	A.M.	− 7
,,	,,	Small Plateau ...	3,635	,,	8.30	,,	− 12·5
,,	,,	Grand Plateau ...	3,932	,,	9.30	,,	− 13
,,	,,	Grand Mulets ...	3,050	,,	1	P.M.	− 8·5

At Chamounix the temperature on Jan. 20 at 7 A.M. was − 11°, at 8 A.M. − 10°, at 10 A.M. − 9°, at 11 A.M. − 8°. The sun began to appear at 11.30.

AT a meeting of the Edinburgh Medico-Chirurgical Society, held on Monday, Jan. 31, Dr. Matthews Duncan read a paper on the alleged epidemic character of erysipelas and puerperal fever. From an elaborate set of diagrams showing the weekly and yearly deaths registered in London from 1848 to 1875, it was pointed out that during the whole of this time erysipelas and puerperal fever have on no occasion exhibited any approach in their death-rate to such diseases as cholera, small-pox, and scarlet-fever, allowed by all to be epidemic in their character, but that the weekly and annual fluctuations in their death-rate are practically identical with those of rheumatism. It was therefore concluded that erysipelas and puerperal fever should be classed not as epidemic but as endemic diseases.

PROF. E. QUETELET has published the climatological elements of Brussels in a series of eighteen tables, with descriptive letter-press, for the ten years ending 1873, as part of a public statistical document of Brussels relative to this ten-year period, and which has been printed with the title "Statistique générale de la Ville de Bruxelles."

IN a circular letter addressed to the Presidents of the Departmental Meteorological Commissions, dated January 29, M. Leverrier points out that, in developing the system of weather-forecasts for agriculturists, attention must be paid not only to the quantity of rain which falls, but also to the way in which the fall is propagated from canton to canton and from department to department. The manner of propagation of the rainfall it is proposed to represent by means of curves, and the Commission are requested to assist in the work so as to render it possible to construct such charts for the whole of France, and in consideration of the immense labour of the undertaking, skilled meteorologists are invited to lend their assistance in the preparation of these novel but highly-important charts. Still greater precision in stating the local circumstances connected with remarkable hail-storms is insisted on, particularly when it is considered that though everyone knows hail to fall in very different quantities in districts immediately contiguous to each other, and individual cantons and communes to be notorious for their destructive hail-storms, yet the influence of woods, forests, river-courses, and hills is a question still unsolved. This conception of Leverrier's with reference to the vitally important bearing on the meteorology of a country of a comprehensive observation of the rainfall, hail, and thunderstorms, by numerous observers possessing sound local information, is not merely eminently just in science, but augurs well for a satisfactory solution of the peculiarly important but difficult problem he has taken in hand.

THE "Annuaire météorologique et agricole de l'Observatoire de Montsouris pour l'An 1876" (pp. 442) has just appeared, containing a good many matters not included in previous issues, of which the most interesting are a chart showing the lines of equal magnetic declination for France and parts of the countries adjoining, a table showing the successive values of the declination from 1550 to 1875, a chapter on atmospheric electricity, a

table giving the mean temperature of Paris for each day of the year, calculated from sixty years' observations, a comparison of the mean hourly observations from March to September, between the thermometer in shade and Becquerel's electric thermometer, fixed at a height of sixty-five feet above the ground; and a variety of tables, partly chemical and partly meteorological, bearing on agriculture.

DR. E. PERCEVAL WRIGHT, M.A., F.L.S., was, on the 5th inst., re-elected Professor of Botany and Keeper of the Herbarium in the University of Dublin.

THE Royal Irish Academy has lately shown a large amount of literary life. Its publications consist, like those of most of our chartered societies, of Transactions and Proceedings. Of the Academy Transactions during the last twelve months twelve parts have been published; it is noteworthy that these parts, each containing a single memoir, have been published within a few weeks after they have been read. Among them we notice Mr. Jellet's memoir on Chemical Optics, Mr. Stoney's report on Riveted Joints, Dr. Macalister's report on the Anatomy of Insectivorous Edentates, Mr. Baker's report on the Seychelles Fern Flora, Dr. Doberck's four memoirs on various Binary Stars, and on the first Comet of 1845, Dr. Hart's memoir on the Nine-point Contact of Cubic Curves, Mr. Mackintosh on Echini Spines, and Prof. King on Jointing. The Scientific Proceedings during the same period have been published quarterly, and the four parts contain thirty-seven memoirs, not of sufficient importance for the Transactions, which are illustrated by thirty-four plates and many woodcuts. One long report by Rev. E. O'Meara on Irish Diatomaceæ will be of interest to all microscopists, while many of the papers by Dr. Macalister, Mr. Archer, Mr. Mackintosh, Mr. Burton, Dr. McNab, Dr. Leith Adams, are of very considerable importance. Speedy publication is the very life of science, and we trust the Irish Academy will indulge, in this respect, in a generous rivalry with the cognate London societies. The separate publication of the memoirs is a boon to the working student, who cannot always afford to buy a large volume of some 600 pages for the sake of perhaps one small memoir.

THE Royal Commissioners on Vivisection have signed their report, which will forthwith be despatched to her Majesty.

M. BERTHELOT, the celebrated chemist, is a candidate in the moderate Republican interest for the representation in the French Chamber of Deputies, of the district in which the Institute is situated.

WITH this month's number of Petermann's *Mittheilungen* is a map of the African west coast from 3° to 6° S. lat., showing the results obtained by the German African Expedition. A short paper by Dr. Güssfeldt states briefly the bases on which the map is constructed. Its special value lies in the fact that it is almost wholly constructed from materials obtained by the personal observation of Dr. Güssfeldt. The same number contains the continuation of the account of the recent Paris Geographical Exhibition. Dr. A. Schreiber, who lived six years in Sumatra, contributes an important paper on the Southern Batta Lands of that island; the paper is accompanied by an excellent and full map of that portion of the island between the equator and $2\frac{1}{2}$° N. lat., and westward of the 100th degree of E. long. The number contains what may be regarded as a complete geographical necrology for 1875. It comprises thirty-six names, and how wide Dr. Petermann's interpretation of the word geography is may be learned from the fact that among these names are those of Sir Charles Lyell, Sir W. E. Logan, and Dr. von Willemoes-Suhm. The number concludes with the continuation of Dr. Conto de Magelhaes' account of his travels in Uruguay.

THE *Geographical Magazine* for February contains a brief but clear account of the work accomplished by Cameron. Major Wood's paper on former physical aspects of the Caspian is continued, and Prof. Giglioli contributes translations of letters from Dr. Beccari, the Italian explorer of New Guinea; a map accompanies these letters.

THE December number of the *Bulletin* of the French Geographical Society contains the abstract of the diary of a Rabbi who recently journeyed from Mogador in Morocco to the Djebel Tabayoudt. The Abbé Durand's valuable paper on the basin of the Madeira, S. America, is concluded, and M. Fournier contributes some recent information on Mozambique and the production of the basin of the Zambesi. M. V. A. Malte-Brun reports on Dr. Van Raemdonck's work on the terrestrial and celestial spheres of Mercator. In connection with the proposed erection of a Central Meteorological Observatory on Mont Pie, Abbé Perrier gives some account of that mountain. It is in the middle of the Graian Alps, 3,593 metres above the sea, nine kilometres from the town of Aosta.

AMONG the notices of motion in the House of Commons on the opening day of Parliament, were one by Sir John Lubbock to introduce his National Monuments' Bill, and another by Mr. Mundella of a Bill for the establishment of Free Libraries, Museums, and Institutions for the Teaching of Science and Art.

THE French Association for the Advancement of Science opens its next Congress at Clermont-Ferrand on August 17 next.

VOL. V. Part II. of the *Natural History Transactions of Northumberland and Durham* contains the Presidential Addresses for 1874 and 1875. The most important contribution to the part is an interesting Memoir of the Life of the late Albany Hancock, by Dr. Embleton, which ought to prove acceptable to all naturalists. A beautifully-executed steel portrait accompanies the memoir, and appended is a list of seventy-three works, mostly contributions to various journals, written either wholly by Mr. Hancock, or in conjunction with some one else. Dr. Embleton also contributes a paper on the Vendace (*Coregonus Willoughbii*, Yarrell, *C. Marænula*, Jardine and Jenyns), and Mr. G. C. Atkinson a second instalment of a Catalogue of the more remarkable Trees of Northumberland and Durham.

ANOTHER catastrophe has befallen the Island of Réunion. On Dec. 22, 1875, a terrific cyclone, accompanied by a thunderstorm, deluged St. Denis, the chief town. The whole island, fifty miles long, by thirty miles broad, was more or less damaged; but the loss of life has been smaller than when the landslip occurred a month previously.

WE have received a copy of the first number of *The American Journal of Microscopy*, a new monthly paper published at New York, which has commenced in an unpretentious manner, the object of the editor evidently being to increase it if he finds that the plan of its construction suits it to the wants of a sufficiently large circle of contributors.

AT the last meeting of the Eastbourne Natural History Society, Dr. Ogier Ward read a paper on the Hill-Forts of Sussex.

THE additions to the Zoological Society's Gardens during the past week include a Panda (*Ælurus fulgens*) from Nepal, deposited; a Hobby (*Hypotriorchis subbuteo*), and a Common Kestrel (*Tinnunculus alaudarius*), captured in the Red Sea, presented by Mr. S. Baton; a Bonnet Monkey (*Macacus radiatus*) from India, presented by Mr. E. Darwell; two Snowy Egrets (*Ardea candidissima*) from America, purchased; a Red-crested Cardinal (*Paroaria cucullata*) from S. America; two Amaduvade Finches (*Estrelda amadava*) from India, presented by Mr. Peter W. Barlow, jun.; a Swainson's Lorikeet (*Trichoglossus swainsoni*) from Australia, presented by Mrs. G. F. Angas.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, Jan. 20.—Certain cases of electromotive force sustained by the action of electrolytes on electrolytes, by J. Hopkinson. Communicated by Sir W. Thomson.

On reversed photographs of the solar spectrum beyond the red, obtained on a collodion plate, in a letter to Prof. Stokes, by Capt. J. Waterhouse, Assistant Surveyor-General of India. Communicated by Prof. Stokes.

Jan. 27.—Contributions to the minute anatomy of the thyroid gland of the dog, by E. Cresswell Barer, M.D., Lond. Communicated by Dr. Klein, F.R.S.

Results of the monthly observations of magnetic dip, horizontal force, and declination made at the Kew Observatory, from April 1869 to March 1875 inclusive, by the Kew Committee.

Researches on the minute anatomy of the alimentary canal, by Herbert Watney, M.A., Demonstrator of Microscopical Anatomy at St. George's Hospital. Communicated by Dr. Klein, F.R.S., Assistant Professor in the Brown Institution.

Linnean Society, Jan. 20.—Prof. G. J. Allman, F.R.S., president, in the chair.—Prof. Oliver communicated a short paper, by Prof. H. G. Reichenbach, being the twenty-ninth contribution to the botany of the *Challenger*, viz., On some Orchidaceæ collected by Mr. Moseley of the *Challenger* expedition, in the Admiralty Islands, Ternate, and Cape York—one of which forms the type of a new section of the genus *Dendrobium.*—The Fungi of Brazil, by the Rev. M. J. Berkeley and Dr. M. C. Cooke. The authors include the collection made by Mr. J. H. Trail in 1874, and state that all the Brazilian fungi yet known amount to but 437 species. Among these there are of Hymenomycetes, 356; Gasteromycetes, 13; Hyphomycetes, 7; Coniomycetes, 5; Ascomycetes, 55; incomplete, 1—total, 437. About 300 of these are confined to Brazil, the remainder found in other parts of the world. The great Brazilian region, therefore, with but 437 representatives, contrasts with 886 enumerated for Cuba, and 1,190 for Ceylon. This paucity of species in the first-mentioned area, the authors suggest, may be due to incompleteness of collection, or presumably as yet deficient knowledge of microscopical forms.—On a new species of oak from the Sikkim Himalaya, by Dr. George King, F.L.S., Supt., Roy. Bot. Gard., Calcutta. This, the *Quercus Andersoni*, or "Katoos" of the Nepaulese, is one of the finest forest trees, and largely used by the European residents of Darjeeling. It occurs at higher altitudes than *Q. spicata*, and in other respects differs.—On Steere's sponge, a new genus of the Hexactinellid order of the Spongidæ, by Dr. James Murie. Obtained in deep water between the islands of Negros and Zebu, the present adds one more rarity to the already remarkable sponge fauna of the Philippines. The siliceous skeleton of *Dendrospongia steereii* bears resemblance to a branching coral or shrub, and is nearly three feet high. A peculiar rosette-like series of tufts form a continuous whorl, winding spirally up the branches. Microscopical examination shows the spicules to belong to the sexradiate type: the character of these, with the presence of a veil and other structural points, indicate its being an intermediate type between such forms as *Dactylocalyx*, *Aphrocallistes*, *Holtenia*, and *Meyerina*. The homology of the so-called root, body, and beard spicules of several of the siliceous sponges being noted, those of *Dendrospongia* are compared; the spiral tufts of the latter agreeing in many respects with the spicular fringes of *Euplectella*, &c.

Chemical Society, Feb. 3.—Prof. Abel, F.R.S., president, in the chair.—Mr. W. Ackroyd read a paper on metachromism, or colour change. Metachromism, from the Greek μετά, change, and χρῶμα, colour, is the term applied to the phenomenon investigated, viz., the change in colour observed in bodies when heated at comparatively low temperatures. For convenience sake colour-changing bodies were called metachromes. No mention is made of the subject in text-books, and only here and there in scattered memoirs. The views of Stahl, Delaval, Brewster, Schœnbein, Gladstone, and Houston and Thomson were spoken of and discussed. *Colour change takes place in the order of the spectrum colours: when a metachrome is expanding, in the violet to red order; when contracting, red to violet order.* Such colour change it was pointed out might be taken as an indication of expansion or contraction, the anomalously behaving body AgI fully bearing out the author's conclusions. Metachromes were divided into two classes: (1) the zinc oxide class; and (2) the borate of copper class. From a study of the two classes the following metachromatic scale was arrived at: white, colourless, violet, indigo, blue, green, yellow, orange, red, brown, black—metallic appearance. The colours of the more refrangible end may be replaced by a metallic appearance. Metachromism has an important bearing on allotropy. A body expanding through the influence of heat being really a continuous series of allotropes. In support of this the relation of colour and density was discussed. It was shown that metachromism is due to the storage of potential energy, the author holding that molecular vibrations or kinetic energy have nothing to do with this phenomenon of selective absorption. Contracting metachromes changing from less to more refrangible colours, where would this change cease providing a long enough temperature could be had? Presumably at the absolute zero of temperature, and at this point all metachromes would be white or metallic-looking, judging from their behaviour at attainable temperatures. Following expanding metachromes from this *absolute zero of colour*, the change in each would vary with the coefficient of expansion, giving us at the normal temperature all that diversity of hue which characterises the inorganic world. Including certain cases of decomposition (given in table) colour change may denote (1) If to more refrangible, α contraction or β decomposition; (2) If to less refrangible, α expansion or β combination. The observations relate to anhydrous and for the most part binary compounds.—Mr. W. H. Perkin, F.R.S., made a communication on the formation of anthra-purpurin, which it appears is the product of the action of caustic alkali on anthraquinone-disulphoric acid. The supposition that alizarin is formed under these circumstances being incorrect.—There were also papers on mattose, by Mr. C. O. Sullivan; on a simple form of gas regulator, by Mr. J. Fletcher; and on high melting points, with special reference to those of metallic salts, by Mr. T. Carnelley, B.Sc.

Zoological Society, Feb. 1.—Mr. G. R. Waterhouse, vice-president, in the chair.—The Secretary read some extracts from a report of a recent visit made by H.M.S. *Petrel* to the Galapagos Islands, communicated by the First Lord of the Admiralty, and referring to the tortoises met with in the different islands of the group.—Mr. Sclater exhibited and made remarks on an antler of a Rusa Deer, living in the Gardens of the Acclimatisation Society of Melbourne, which had been sent to him for identification.—Mr. Frederick Selous, jun., exhibited and made remarks on a series of horns of African Rhinoceroses procured by himself in South-eastern Africa.—Prof. T. H. Huxley, F.R.S., read a paper on the position of the anterior nasal aperture in Lepidosiren, which he showed to be strictly homologous with the position of these organs in other vertebrates.—Mr. A. H. Garrod read a paper on the anatomy of *Chauna derbiana*, and on the systematic position of the Screamers (*Palamedeidæ*), in which he controverted Prof. Parker's collocation of this form with the Anseres, and showed that it should occupy an independent position with relations to the Struthiones, Gallinæ, and Rallidæ.—A communication was read from Mr. F. Jeffrey Bell, containing notes on the myology of the limbs of *Moschus moschiferus.*—A communication was read from Dr. T. Spencer Cobbold on Entozoa, forming the third of a series of papers on this subject brought by him before the Society.—Mr. Herbert Druce read a list of butterflies collected in Peru, with descriptions of new species. To these were added some notes on some of the species, by Mr. Edward Bartlett.—Mr. A. G. Butler read some notes on a small collection of butterflies received from the New Hebrides.—A paper by Mr. P. L. Sclater and Mr. O. Salvin was read, in which they gave descriptions of some new birds obtained by Mr. C. Buckley, in Bolivia.

Physical Society, Jan. 29.—The president, Prof. Gladstone, F.R.S., in the chair.—The following candidates were elected members of the Society:—Sir John Conroy, Bart., and H. S. Burls.—The Secretary then read a communication from Mr. J. A. Fleming on the polarisation of electrodes in water free from air. The experiments described were undertaken in order to meet objections which had been raised by Prof. Rowland to a previous paper by the author, in which he endeavoured to show that when an electrolyte flows in a very strong magnetic field the electromotive force generated by its motion effects the electrolysis of the liquid, a fact which he holds to be proved by the subsequent polarisation of the electrodes. Prof. Rowland considered that the effect observed was due to the presence of dissolved air, and conversely, that in air-free water, at any rate with the same electromotive force, similar effects would not be observed. These doubts raise the two questions (1) in air-free water can platinum electrodes be polarised by a very small electromotive

force to the same degree and with the same facility as in aërated water, and (2) is this very feeble polarisation really a decomposition of the electrolyte? To test the first point experiments were made with a voltameter containing dilute sulphuric acid which had been previously boiled, the voltameter being connected with a Sprengel pump. The platinum plates were acted on by a very small external electromotive force for one minute, and the effect of the polarisation current due to this action noticed on an extremely delicate galvanometer, the effect of the direct current employed being also noted. After a series of observations had been made, using different amounts of electromotive force, the dilute acid was removed, and, after being thoroughly aërated, replaced in the voltameter. On repeating the experiments with this one change in the conditions, the results obtained were almost identical, from which fact the author concludes that the first question may be answered in the affirmative. With regard to the second, Mr. Fleming believes that the assertion that polarisation is decomposition of the electrolyte has never been called in question, and in proof of it, describes an experiment showing that when acidulated water flows rapidly past slightly polarised plates, the current which they give is very much diminished, while by causing the water to flow slowly but slight change is produced. This seems to indicate that there is something on the plates which can be *wiped off* mechanically, and it can only be a product of electrolysis.—Prof. Foster, while admitting the accuracy of Mr. Fleming's experiments, doubted whether he was justified in definitely ascribing polarisation to chemical action. He thinks that, even though the effect be proved not to be due to dissolved air, we must look for some cause other than chemical action. For it has long been acknowledged that the decomposition of water requires an electromotive force considerably in excess of that employed in these experiments.—Prof. Gladstone then made a brief communication on the photography of fluorescent substances. He exhibited several photographs taken of white paper on which devices had been previously drawn, with solutions of sulphate of quinine, œsculine, &c., and one was taken in the room. He remarked that the leaves of trees come out dark in a negative, as they contain the fluorescent substance chlorophyll, and suggested that the irregularities of colour observed in photographs of oil paintings are probably due to the intermixture of fluorescent substances in the paints used.—Mr. Meldola referred to Prof. Vogel's experiments on the effect produced on the resulting photograph by the addition of a fluorescent substance to the collodion, thereby increasing the sensitiveness of the plate to particular rays.—Mr. S. P. Thompson, B.A., B.Sc., then gave a summary of the recent experiments made in America by Mr. T. E. Edison, Dr. Beard, Prof. Houston, and others upon the new phase of electric manifestation, the so-called etheric force. This force is characterised by a faint spark, the only evidence, in fact, yet known of its existence. It may be obtained from the iron core of any electro-magnet, or from a metallic bar slipped into the coil in place of the core, but only when the battery circuit is being interrupted, as may be done by introducing into the circuit an automatic contact breaker. The sparks so produced are apparently without polarity, devoid of chemical or physiological effect, affect neither electroscopes nor galvanometers, and are stated to be retroactive, being exhibited when one end of a wire through which they are passing is brought round to touch the wire. A detailed description was then given of experiments on this force conducted in the Physical Laboratory at South Kensington, some of which were confirmatory of the published researches of the discoverers, while others were at variance with them. Great pains had been taken to avoid leakage and to distinguish the effects from those of ordinary induced currents. The batteries and coils employed were insulated from the earth as well as from the other portions of the apparatus. A bar of zinc placed above the poles of a powerful electro-magnet, or within its coils, was found to give better results than one of cadmium, which is recommended by the discoverers. The sparks, which resembled those of dynamic electricity, were of inappreciable length and far too faint to ignite gun-cotton or illuminate a delicate Geissler's tube. It was also found that when a bar of zinc was placed within the coil of an electro-magnet in the place of its core and joined by a wire to the gas fittings of the building, faint but distinct sparks could be drawn from any portion of this wire by a second wire proceeding from another part of the gas pipes. Another peculiar effect was observed when the wire attached to one end of the zinc bar, and armed at its extremity with a thin iron wire, was rubbed lightly against the other end of the zinc bar—sparks being thus obtained, apparently passing from one pole of the zinc bar, through the wire, to the other.—Dr. Stone believed he had detected a distinct galvanic taste on applying to the tongue the wire through which the "force" was passing.—Prof. Foster suggested the use of an electro-dynamometer to ascertain the electromotive force of the current exhibiting these sparks, as its indications would be independent of direction of current.

Royal Microscopical Society, Feb. 2.—Anniversary Meeting.—H. C. Sorby, president, in the chair.—The Report of the Council and the Treasurer's Annual Statement of Accounts were submitted to the Fellows, and showed that the Society was, at the present time, in a satisfactory and prosperous condition. Votes of thanks to the President and Council for their services during the past year were proposed by Mr. J. Glaisher and carried unanimously. The President then delivered the address, the subject of which was the probable limit of the powers of the microscope with reference to the ultimate size of the molecules of matter, and the general bearing of the conclusions arrived at upon the various germ theories. The following gentlemen were elected as Officers and Council for the ensuing year:—President, Henry Clifton Sorby, F.R.S. Vice-presidents: Charles Brooke, F.R.S., William B. Carpenter, F.R.S., Rev. W. H. Dallinger, Hugh Powell. Treasurer, John Ware Stephenson, F.R.A.S. Secretaries: Henry J. Slack, F.G.S., Charles Stewart, F.L.S. Council: Robert Braithwaite, F.L.S., Frank Crisp, LL.B., John E. Ingpen, Emanuel Wilkins Jones, F.R.A.S., William T. Loy, Henry Lawson, M.D., John Millar, F.L.S., John Rigden Mummery, F.L.S., John Matthews, M.D., Frederic H. Ward, M.R.C.S., Francis H. Wenham, C.E., Charles F. White. Assistant Secretary, Walter W. Reeves.

Institution of Civil Engineers, Feb. 1.—Mr. Geo. Rob. Stephenson, president, in the chair.—The paper read was on the "Holyhead New Harbour," by Mr. Harrison Hayter, M. Inst., C.E.

Victoria (Philosophical) Institute, Feb. 7, Mr. C. Brooke, F.R.S., in the chair.—After the election of new members it was stated that during the past year thirty-three town, sixty-four country, and eighteen foreign and colonial members had joined. A paper on "Heathen Cosmogonies compared with the Hebrew" was read by the Rev. B. W. Savile.

PHILADELPHIA

Academy of Natural Sciences.—During 1875 a large number of interesting papers and communications were read.—Prof. Cope, in describing some vertebrate fossils from the Saskatchewan district, said that they gave indications of the future discovery of a complete transition from Cretaceous to Eocene life. The collection was chiefly remarkable for the great number and variety of Dinosaurian remains. In another paper Prof. Cope attempted to trace the evolution of the sectorial tooth of Carnivora from the simple quadri-tuberculate molar. He regards the process as having consisted first in an addition of an anterior cusp, and subsequently in the loss of internal and posterior cusps. There had been a progressive extinction of genera with numerous sectorial teeth, with an increasing specialisation of the sectorial tooth in the surviving genera. Parallel with this change was another, in the character of the tibio-astragalar articulation, which he believed to indicate that the American Eocene Carnivora were plantigrade. In describing a new Mastodon from Santa Fé, Prof. Cope divided the North American Mastodons into two groups, the first having teeth with continuous cross-crests divided by a fissure only, the other having transverse series of two or more deeply-separated tubercles. Comparatively recently Prof. Cope announced the discovery of vertebræ and other remains from Illinois, which appear to give the first definite indication of the existence of Rhynchocephalous lizards in the western hemisphere.—Prof. Leidy's contributions have referred chiefly to Rhizopods and Vermes, and to Vertebrate Palæontology. He described a remarkable Rhizopod, which he compared to the reticular pseudopods of a Gromia separated from the body. At one time it appeared as an extremely thin disc with a multitude of minutely ramified and anastomosing pseudopods proceeding from its edge. At other times it divided up into branches from a trunk like a tree. Again it would assume the form of a cord, and the jelly accumulating at some portion of it would run along it like a drop of water on a piece of twine. A granular circulation was observable as in Gromia.—Mr. T. G. Gentry presented an important paper on the phylogeny of the Lepidoptera, suggested by an anomalous development of certain larvæ of *Acronycta oblinita*, without the slightest attempt at cocoon-making.

Other instances among insects were adduced to show the important influence of the surroundings of a species in producing functional changes in its economy, and it was sought to be established that defective nutrition has been a principal cause of cocoons being dispensed with by certain Bombycidæ. From these preliminary considerations the author proceeds to consider the evolution of the various families of Lepidoptera. He believes that the butterflies have as a whole been developed from the Bombycidæ, though that development has probably been accomplished through several roads. He claims the support of palæontological evidence for his views. The earliest moths yet recorded are the Tineids, the lowest family of Lepidoptera; these may be regarded as constituting a persistent type like that of Terebratulas. The Sphinges are supposed to have descended from a Phryganea with Bombycid characters, and many ingenious suggestions and considerations are advanced in support of this view. A hypothetical genealogical tree is given at the close of the paper.—A monographic account of *Nisus* (*Accipiter*) *cooperi* and *N. gundlachi*, by Mr. R. Ridgway, gives the results of careful examination of many specimens. With regard to the former it is found impossible to establish the existence of two geographical races. The distinctness of the latter species is strongly maintained. Mr. Ridgway's account of the Buteonine sub-genus, Craxirex, which is peculiar to America, gives a synopsis of the species. The very variable *Buteo swainsoni* is particularly fully described.—A very interesting paper is contributed by Dr. Elliott Coues, devoted to a vindication of William Bartram as a scientific ornithologist. Dr. Coues seeks to prove that, according to the admitted rules of nomenclature and the rules of the British Association, Bartram has not received his due. He maintains that Bartram's Catalogue of United States Birds is not a mere valueless list, but all the more valuable in consequence of the terseness and simplicity of his descriptions, many of which are unmistakable.—One of the most important papers of the year is by Dr. Lautenbach, on the physiological action of hemlock and its alkaloid. His conclusions, from careful experiments, are as follows:—1. Conia, instead of being poisonous to plants, really acts as a preservative; the alcoholic extract of hemlock, however, acts poisonously on plants. 2. When locally applied, conia produces a progressive loss of functional power in every highly organised tissue with which it comes into contact. 3. In inducing complete repose of the muscular system, conia powerfully predisposes to sleep, but it is not a hypnotic in the sense that opium is. 4. The convulsions produced by a poisonous dose of hemlock are cerebral, and not spinal, as has heretofore been imagined. 5. Conia produces a double effect on the motor-nervous system, a paralysing effect on the periphery of the efferent or motor nerves, and a depression of the motor tracts of the spinal cord. 6. The increase in the number of heart-beats which occurs early in conia poisoning is due to paresis of the pneumogastrics. 7. The primary acceleration in the respiratory movements is also due to pneumogastric paresis. 8. The salivary secretion is the only secretion markedly increased by a poisonous dose of conia. 9. The voluntary muscles escape unscathed in conia-poisoning. 10. Contraction of the pupil only occurs when the drug is directly applied to the eyeball. 11. Conia causes a decided increase in temperature. 12. Conia is absorbed and is eliminated unchanged by the kidneys.

Paris

Academy of Sciences, Jan. 31.—Vice-Admiral Paris in the chair.—The following papers were read:—Thermal researches on the formation of alcohols and on etherification, by M. Berthelot.—Account of experiments made to determine the work expended by Gramme's magneto-electric machines, used for producing light in the works of MM. Sautter and Lemonnier, by M. Tresca. A direct-illumination photometer was used for comparing an electric lamp with a Carcel lamp, and when equality was had in the two contiguous zones, a dynamometer trace was taken, and the number of turns ascertained. The author gives data of machines, the light from which was equal to 1,830 and 300 Carcel burners respectively. The cost of fuel for the former was only about a hundredth of that of the oil and a fiftieth that of the coal gas.—M. Du Moncel presented the fourth volume of his "Exposé des Applications de l'Electricité" (3rd edition), relating to electric clockwork, electric registers, and applications of electricity to safety appliances in railway service.—Researches on magnetic rotatory polarisation (2nd part), by M. Becquerel. The rotation in diamagnetic bodies increases with the index of refraction. In solutions of a diamagnetic salt of varying concentration, the ratio of the rotation to the weight of the anhydrous salt is a number nearly constant. With salts of iron the magnetic rotation increases much more quickly than the number of active molecules.—Calorific vibrations of a homogeneous solid of uniform temperature, by M. Lucas.—On the formation of hail (second note), by M. Planté. The electrodes of the secondary couples are introduced into salt water, the positive being covered with moistened blotting-paper. A multitude of ovoid globules are scattered out and up from this latter in all directions. M. Planté thinks the electricity in clouds may sometimes act thus, and the globules, rising to a region of lower temperature, become hailstones. Electricity may produce hail through mechanical, calorific, or magneto-dynamic effects.—Letter to the President of the Commission on Phylloxera, by M. Mouillefert.—On the boring operations in the tunnel of Saint Gothard, by M. Colladon. Notwithstanding much greater hardness of rock, &c., than in the boring of Fréjus, M. Favre has, in the third year, realised an advance of 48½ per cent. above the maximum obtained in Fréjus during the thirteen years.—Discovery of the planet (159), by M. Paul Henry.—Note on left curves of the fourth order, by M. Serret.—On the principle of correspondence, and the means it affords of removing some difficulties in analytical solutions, by M. Saltel.—On topographic maps, by M. Hermite.—On the congelation of mercury by use of a mixture of snow and hydrochloric acid, by M. Witz. A mixture, in equal parts, of snow and hydrochloric acid having a temperature of $-1°$, will give a temperature of $-37°\cdot5$ C.—On electrolytic aniline black, by M. Goppelsroeder.—On the ferment of urea, by M. Musculus. It has none of the properties of organic ferments, but is rather like soluble ferments, as diastase, saliva, and pancreatic juice.—On the elements of inverted sugar, and their presence in commercial sugar, by M. Maumené.—On digestion in insects; remarks *àpropos* of a recent work of M. Jousset, by M. Plateau. M. Plateau claims priority of observation.—Note on the method to be employed for testing the conductivity of lightning conductors, by M. Michel.—Observations relative to the undulations and fractures of the Cretaceous system, *àpropos* of the project of making a tunnel under the Channel, by M. Robert.—On spontaneous periodic movements in the stems of *Saxifraga sarmentosa*, *umbrosa*, *Geum*, *Acanthifolia*, and in *Parnassia palustris*; relations of this phenomenon with the disposition of the foliar cycle, by M. Heckel.

THE LISBON MAGNETIC OBSERVATIONS

Annaes do Observatorio do Infanto D. Luiz. Magnetismo Terrestre. Lisbon Imprensa Nacional. (1870, 1874.)

THAT in 1858 Portugal entered into "the Magnetic Union of Nations, founded by Gauss and by Humboldt in 1832," was due to the enlightened solicitude of the King Luiz I. for the progress of science. The observatory founded by him at Lisbon, and placed under the care of the late Mr. de Silviera, has during the last years been directed by Mr. de Brito Capello, who had previously the oversight of the magnetic department, and to whom we believe the results in the two parts of Annals before us are chiefly due.

The value of the Lisbon observations and of these results is so much the greater that the neighbouring country, Spain, has done nothing for terrestrial magnetism, and even France, which stands so high in science, has given us no such series of observations since Arago originated them by the devotion of years to the movement of the magnetic needle.

The first part of the Annals before us (1870) treats of the results for the magnetic declination derived from direct observations made at 8 A.M. and 2 P.M. (1858-1868), and for the diurnal variations (1864-1868) from a photographic registering apparatus similar to that at Kew. The secular variation is first investigated. This mysterious movement, which we can attribute to no known cause, as it has no known period, is shown at Lisbon by a mean approach of the north end of the needle to the north at the rate of 5'·9 a year during ten years, but varying from a minimum of 4'·8 in 1858-9, to 8'·2 in 1866-7. An annual law has also been found consisting of an oscillation of 1'·5, the needle being nearest the north in June, and farthest from it in December and January.

The diurnal variation at Lisbon resembles to a considerable extent that obtained at more northern stations in Europe. The periodic variation of the mean range of this oscillation, first discovered by Dr. Lamont, which occupies from ten to twelve years, has also been found at Lisbon. This investigation has its importance increased by the fact that the greatest and least mean oscillations happen at the same times as the maximum and minimum frequency of solar spots. The coincidence first indicated by Sir E. Sabine, with reference to magnetic disturbances, was remarked independently by Dr. Rudolph Wolf, of Zurich, who has made it the subject of an extensive and valuable series of investigations. Dr. Lamont, commencing with Cassini's observations, has found the mean duration of the magnetic period to be 10·43 years, while Dr. Wolf obtains 11·11 years from a longer, though perhaps less certain, series of solar spot observations. Since there can be no doubt that the yearly variation of sunspots and of the amplitude of the diurnal oscillation of the magnetic needle follow the same law and depend on the same cause, every new determination of the epochs of maxima and minima is of value, fixing points which will determine the mean duration and variable length of the period, and thus probably lead us to a knowledge of the common cause. The Lisbon observations give 1859·9 and 1867·0 as epochs of maximum and minimum, agreeing very nearly with those derived from the Munich and Trevandrum observations. In the determination of the mean duration, everything depends on where we commence. If we begin with Arago's magnetic observations, the mean duration is about 10·7 years; if we take the most accurate results for the sunspot area from Messrs. De la Rue, Stewart, and Lœwy, we find 11·2 years, nearly that deduced by Dr. Wolf. Evidently a much longer series of accurate observations is required to determine the length of a period which has varied between 8 and 12·3 years within the last half century; though we believe Dr. Lamont's result to be nearly true.

As the Observatory establishment was not sufficient for the long calculations required for the investigations connected with the lunar diurnal variation, the latter was sought approximately from the effects of the lunar action in diminishing or increasing the solar diurnal oscillation at different days of the moon's age. It was thus found that the diurnal oscillation from 8 A.M. to 2 P.M. was greatest when the moon was three and eighteen days old, while it was least when she was ten and twenty-four days old. This indicates a semi-diurnal oscillation due to the moon's action, with an amplitude of 1' nearly, having the maximum westerly positions when the moon is near the upper and lower meridians.

It is remarked by Mr. Capello, with reference to disturbances, that in many cases the observations taken as disturbed (those differing from the normal position by 2'·26 or more) were, properly speaking, not disturbed observations, but belonged to very regular curves, in which the morning minimum was more marked or the afternoon maximum was less so than usual. Whereas disturbances are shown by serrated curves. This remark is quite exact, and the fact becomes even more marked in lower latitudes. The investigation for the lunar variation just noticed will show one cause for this variation of the amplitude of the diurnal oscillation which is greater the greater the lunar action.

The second part of the Annals before us (1874) contains the discussions for the other magnetic elements. Mr. Capello finds, from nine years' observations, that the horizontal force of the earth's magnetism was greatest in July, least in September, with a secondary maximum in November, and minimum in February. This result depends on few observations, but approaches considerably to that obtained first at Makerstoun. The very marked minimum found for the month of September induced Mr. Capello to examine whether this might not be due to the action of disturbances, which in general diminish the earth's magnetic force; it results from this discussion that though the disturbances have a considerable effect in increasing the amplitude of the annual oscillation, yet the maximum in December is best marked in years of least disturbance. This result he confirms by an examination of the Kew observations, and it agrees with that deduced from each of a series of years' observations of the bifilar at Makerstoun. Mr. Capello also finds that the Munich observations show the most marked minimum in September and October, in years of least disturbance. It is an important fact, confirmed by the results from many observatories, that the horizontal force of the

earth's magnetism is a maximum near the solstices, and a minimum near the equinoxes.

The diurnal variations of horizontal force, deduced from the photographic registration of the bifilar magnetometer, follow laws similar to those at Munich, and not differing greatly from those at Makerstoun, 17° further north; the minimum, however, shifting from near 9 A.M. in summer to about 2 P.M. in winter.

The balance magnetometer seems to be the least certain of the variation instruments at Lisbon. The temperature coefficient (obtained by heating the air with gas jets) has been found with an opposite sign to that due to variations of the needle's magnetism, a result which is always unsatisfactory even when the variations of temperature are small as they are at Lisbon. The diurnal variation of the vertical magnetic force differs considerably from that obtained at more northern observatories, the minimum occurring in each month of the year near noon, and the maximum near 5 P.M.

Mr. Capello has evidently bestowed much pains on the determination of his instrumental constants, and this publication of results contains a valuable contribution to our knowledge of the magnetic laws for an important station, near the most southerly and westerly point in Europe. Lisbon, like nearly every other magnetic observatory, has been obliged to be satisfied with single instruments of each kind. When so many observatories were founded between thirty and forty years ago, there was perhaps an over confidence in the excellence of the instruments employed, and in the certitude of being able to correct the observations to be obtained from them for every possible error. There was also the economical consideration connected with the expense of a double series of instruments, as well as the additional labour incurred in observing two instruments for the same purpose. The consequence has been, to take a single illustration, that no two observatories have given exactly the same law for the annual variation of the mean position of the magnetic needle. One observatory has contradicted another, the results from a good instrument have been balanced by those from a bad one, and in other cases it has not been possible to determine whether the differences found at two stations were really due to difference of locality only, or to instrumental causes.

When we remember the vast labour (to omit every other consideration) expended in obtaining the laws of magnetic variations, it cannot be too much regretted that every observatory was not furnished with a double series of instruments, which would have shown by their agreement or disagreement the accuracy or error of the results obtained from them. In the case of disagreement the director of the observatory would have been warned that some error existed whose cause should be sought out. No preliminary trials can ensure that an instrument will remain with exactly the same errors. If we could suppose that the captain of a ship would set sail on a lengthy and costly voyage with a single chronometer, without any means of verifying the accuracy of its going except the meeting with another ship in a like predicament, and should then find that, according to their chronometers, they were on opposite sides of the globe, we should have a parallel to a not uncommon case in the work of many magnetic observatories.

It is to be hoped for the future that such differences will not be allowed to exist, that each observatory will have the means of proving that, for its locality at least, the laws obtained are true, and that in publishing the observations, the differences of the indications of two instruments of each kind will be given with the most complete exposure of their errors and corrections.

JOHN ALLAN BROUN

MARSDEN'S "NUMISMATA ORIENTALIA"

Marsden's International Numismata Orientalia. Part II. Coins of the Ursuki Turkomans. By Stanley Lane Poole, Corpus Christi College, Oxford. (London: Trübner and Co., 1876.)

THIS is the second part of the series of separate publications on the Early Coins of the East, of which the first part on Ancient Indian Weights was reviewed in NATURE, vol. xii. p. 24. The whole work is intended to be a new edition of Marsden's "Numismata Orientalia," but in consequence of the new form of the work and its enlarged character, the editor has changed its title into that of the "International Numismata Orientalia."

Part II. has been undertaken by Mr. Stanley Lane Poole, and treats of the Coins of the Ursuki dynasty. Ursuk was one of the petty chiefs of Syria during the wars of the Crusades, in which he distinguished himself, and was made Governor of Jerusalem, A.D. 1086. His descendants, the Ursuki princes, were amongst the most powerful chiefs in Syria and Mesopotamia, until the dynasty was brought to a close by the Tartar invaders, A.D. 1242. An historical sketch of the Ursuki family is given by Mr. Poole as an introduction to the account of their coins.

The series of Ursuki coins described in the work, the greater part of which are now in the British Museum, are mostly copper coins, a few only being of silver. Several plates with clear lithographic and photographic representations of the coins form part of the work. The coins all bear Arabic inscriptions, some of considerable length, and they appear to be of much historical value. In the description of the several coins in the text of the work the old Arabic inscriptions on each coin are given in the more modern Arabic character, according to the system of transliteration adopted in the book. These inscriptions are, however, intelligible only to Arabic scholars, as no English translation is given, which would have added considerably to the interest of the work for general readers.

At the commencement of the Ursuki dynasty the Mahometan moneys were of three classes—gold, silver, and copper, the respective units being the *dinar*, *dirhem*, and *fels*. But the Ursuki coins, both copper and silver, appear to be *dirhems*, this word appearing in the inscription of many of the coins, and showing that they were intended to pass as *dirhems*. Some of the copper coins have a thin coating of silver, and one has been gilded.

The Ursuki princes were amongst the few Mahometan dynasties that introduced images on their coins. But they rarely, if ever, engraved their own heads or those of their suzerains on their coins, choosing instead the types of the gold coins either of the Byzantine Emperors or of the Greek Kings of Syria.

The few silver coins of the series weigh about 44 grains, or 2·9 grammes each. The copper coins vary in weight from 43 to 163 grains, or 2·8 to 17·0 grammes.

The Arab systems of money and of weight are treated at great length in Queipo's "Systèmes Métriques et Monétaires des Anciens Peuples." The earlier gold unit was the *dinar*, and the later gold unit the *michtal*. The *dinar* was the monetary unit, from the Roman *denarius*. The *michtal*, which signifies weight, was the unit of monetary weight. Queipo gives a list of 263 gold dinars of the ancient Eastern caliphs which are now in various numismatic cabinets, with their weights. No coins were struck by Mahomet and his successors, who used the existing coinage of the countries, until the 78th year of the Hegira, when both gold and silver coins were struck by Abdelmelik, Caliph of Bagdad. The mean or normal weight of the gold dinar was 66 grains, or 4·25 grammes. This was the weight of the Attic drachma, from which it was evidently derived. There were also gold coins of $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{8}$, and $\frac{1}{12}$ *dinar*.

The relation of the weight of the Arab silver *dirhem* to the gold *dinar* was as 7 to 10, or nearly as 2 to 3. Queipo gives a list of 592 Arab silver *dirhem* coins of Arabian caliphs from A.D. 699 to 1195, with the weight of each coin. This varied from about 2·5 grammes in the earlier part of this period up to a maximum weight of 3·1 grammes in later times, the mean weight of the *dirhem* being 2·84 grammes, or 44 grains. He mentions also silver coins of $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{1}{4}$ dirhem. The half *dirhem* was thus nearly equivalent to our Saxon penny, the $\frac{1}{240}$th of a pound of silver, and weighing $22\frac{1}{2}$ troy grains.

Queipo makes but little mention of the Arab ancient copper moneys, except to throw a doubt on the existence of the *fels* as a copper coin, and to assume that it was only money of account, and also that the number of *fels* in a dirhem expressed merely the number of units corresponding with the value of copper in relation to silver. He shows that in the first centuries of the Hegira, the value of silver to gold was as 1 to 13, and of copper to silver as 1 to 120. If, therefore, a gold dinar weighed 4·25 grammes, its equivalent in copper would weigh 6,630 grammes; and as the number of *fels* in a *dinar* could not have exceeded 98, that this would give the improbable weight of 67·65 grammes to each copper *fels*. This was the weight of the Attic drachma, from which it was evidently derived. There were also gold coins of $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{8}$, and $\frac{1}{12}$ dinar.

The relation of the weight of the Arab silver *dirhem* to the gold *dinar* was as 7 to 10, or nearly as 2 to 3. Queipo gives a list of 592 Arab silver *dirhem* coins of Arabian caliphs from A.D. 699 to 1195, with the weight of each coin. This varied from about 2·5 grammes in the earlier part of the period up to a maximum of 3·1 grammes in later times, the mean weight being 2·84 grammes, or 44 grains. He mentions also silver coins of $\frac{1}{2}$, $\frac{1}{3}$, and $\frac{1}{4}$ dirhem. The $\frac{1}{2}$ dirhem was therefore nearly equivalent with our Saxon penny, $\frac{1}{240}$th of the pound of silver, and weighing $22\frac{1}{2}$ troy grains. Queipo makes but little mention of the Arab copper money, except to throw a doubt on the existence of the *fels* as a copper coin, and to assume that it was only money of account, the number of *fels* in a dinar expressing merely the number of units corresponding with the relative value of silver and copper. He shows that in the first centuries of the Hegira the value of silver to gold was as 1 to 13, and of copper to silver as 1 to 120. If a gold dinar weighed 4·25 grammes, its equivalent in copper would be 6,630 grammes, and as the number of *fels* in a *dinar* could not be more than 98, this would give the improbable weight of 67·65 grammes to each copper *fels*.

VAN BENEDEN'S "ANIMAL PARASITES"

Animal Parasites and Messmates. By P. J. Van Beneden, Professor at the University of Louvain, &c. (London: Henry S. King and Co., 1876.)

THIS work forms the twentieth volume of the International Scientific Series. We believe there was some doubt on the part of the publishers as to the propriety of bringing out a popular treatise on so uninviting a subject. To have omitted all account of this important series of creatures considered in relation to the welfare of man would, however, have been a serious blunder. It is high time that popular prejudices should be ignored, especially when the welfare of the people themselves is involved in the question at issue. Fully alive to the prejudices referred to, a writer in *Notes and Queries* (who was probably anxious to make the subject palatable) says of this little book: "There is as much amusement to be derived from Prof. Van Beneden's pages as there is instruction." We cannot take this optimist view of the matter; on the contrary, we fail to find anything amusing in the book, although, as might be expected from the author's known position as a man of science, there is much to be learnt from an attentive study of the text. Prof. Van Beneden's strength lies in a clear exposition of the phenomena of commensalism. We owe to his remarkable zoological acumen the correct interpretation of those singular phases of parasitic life which he has so happily classed under the *rôle* of Messmates and Mutualists, respectively. On this head he has strung together such a multitude of facts that his work cannot fail to be useful to working naturalists. Whether the general reader will find anything "amusing" in these pages is very doubtful. He may, indeed, if his mind be still dominated by the teachings of a certain school, find comfort in the assurance which M. Van Beneden affords that the welfare of all the most repulsive forms of insect life is most carefully looked after. What a comfort it must be for the poor Cayenne convict when tortured by insect parasites to know that the ever-helping "Hand" superintends the "preservation" of the larvæ of *Lucilia hominivora* with the same care that it does "the young brood of the most brilliant bird." Surely the Mexican soldier who "had his glottis destroyed, and the sides and the roof of his mouth rendered ragged and torn, as if a cutting punch had been driven into those organs," could hardly be brought to realise the need-be for such a process of development on the score of benevolence towards this frightful parasite! The case of *Lucilia* is by no means exceptional, since there are scores of parasites, both external and internal, that are capable of inflicting the most terrible sufferings alike upon man and beast. Push our author's Bridgewater-treatise-like views to their logical outcome, and it necessarily follows that every pang endured by countless

suffering hosts was expressly designed in order that man might appreciate the benevolence of the "Creator." Such a conception is too horrible to be entertained by reasonable creatures; nevertheless, it is in perfect harmony with certain other grossly anthropomorphic conceptions of Deity that are too commonly taught amongst us.

The general reader will not be able to follow M. Van Beneden very closely, unless he possesses a considerable amount of zoological knowledge; and he will find the book overladen with scientific terms. The naturalist, on the other hand, will be disappointed by the paucity of literary references. Whilst our author shows himself to possess a profound knowledge of the facts of commensalism, his volume is very deficient in the treatment of the subject of parasitism, properly so called, more especially when he deals with those forms that are known as Entozoa. He has omitted all mention of some of the most important helminthological contributions and discoveries of recent times. Thus, there is no allusion to Lewis's "find" respecting nematoid hæmatozoa, and almost nothing is said of the ravages produced amongst domesticated animals by a variety of well-known internal parasites. In some places our author misleads, as in the case of the history of the discovery of *Trichina*, where Sir J. Paget's name is altogether omitted; and also, in the case of *Bothriocephalus*, where Knoch's views on the possibility of infection without the necessity of an intermediary bearer appear to be countenanced.

Some of the illustrations are very poor, and the misspelling of authors' names and of technical words is exceedingly frequent. The author appears to be but little informed respecting the writings of German and English helminthologists. Notwithstanding these defects, M. Van Beneden's book ought to be purchased by every intelligent naturalist. T. S. COBBOLD

OUR BOOK SHELF

The Scholar's Algebra: an Introductory Work on Algebra. By Lewis Hensley, M.A. (Oxford: Clarendon Press; London: Macmillan and Co., 1875.)

THIS is one of the Clarendon Press Series, hence we are saved all necessity of remarking upon the get-up of the volume. We had hardly expected that Mr. Hensley could have imparted any freshness to his treatment of so hackneyed a subject as an Elementary Algebra, but he has done so, and we have read his work with much interest. It does not follow the usual course observed in similar treatises either in its contents or in their arrangement. Our author himself expressly states that the work professes to be an introductory one on algebra. He takes up the scholar who has been well-grounded in arithmetic and endeavours to explain from the outset what algebra is, what its aims, and what the chief forms of its utility. In this attempt he has succeeded, and the work is likely to be of use to students who are reviving an acquaintance with the subject acquired at school, but especially is it suited to self-taught students. For these latter it is, we think, one of the best text-books hitherto brought out. The first seventy pages are devoted to the symbols, signs, and elementary rules; in this section we have a good chapter on Ratio and Proportion, including a glance at incommensurables. Though treated at this length, the scholar is hardly likely to grow weary in his work, and he is laying at the same time a safe and solid foundation for future use.

In Part II. we have Algebraical formulæ (Interest, the Progressions), then Equations (Simple and Quadratic), next Investigation of Methods (Involution and Evolution), closing with a supplement on unknown quantities, Inequalities, Indices (fractional and negative). The third Part opens up to the student under Algebraical formulæ, Permutations, Binomial Theorem, Notation, Harmonic Progression, and simple series, then Equations (more advanced than the previous ones), Surds, Indeterminate Equations and applications of Horner's method. We have then a chapter on Continued Fractions[1] and another on Logarithms. Some idea of the character of the work will be got from the order and nature of the subjects above mentioned, and it will be seen that a prominent feature is the importance attached to methods of calculation. Indeed, Mr. Hensley says he has remarked in the Universities a growing disposition to compel the student of the higher mathematics to interpret his results numerically. To this he gives the weight of his experience: "There can be no better guarantee that he understands what he is about." We may mention that the extension of meaning of the negative sign and of symbols generally, though but slightly glanced at, is yet introduced to the reader's notice. No place is given to properties of numbers, multinomial theorems, convergency of series, higher series, or probabilities. The curriculum is much that laid down by the London University for candidates for the first B.A. (Pass), and we can recommend the book before us as one well suited for such candidates, as containing all they require, and but little beyond what they need take up for the examination.

We shall touch lightly here upon the errata. They are not very serious, and though somewhat numerous, do not by any means come up to the usual standard in this respect of first editions. On p. 98, line 5, for youngest read eldest; p. 127, last three lines, statements should be *vice versâ*; p. 205, line 5 up, read 7×52.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Fritz Müller on Brazil Kitchen Middens, Habits of Ants, &c.

[MR. CHARLES DARWIN has kindly sent us for publication the following letter, addressed to him by Herr Fritz Müller, the well-known naturalist, brother of our contributor, Dr. Hermann Müller, and who has for so long been devoting himself to natural history researches in Brazil.]

My dear Sir,—In Desterro I met with two young men (M. Charles Wiener, of Paris, and M. Carl Schreiner, from the National Museum of Rio) who, by order of the Brazilian Government, were examining the "Sambaquis" of our province. I accompanied them in some of their excursions. These "Sambaquis," or "Casqueiros," are hillocks of shells accumulated by the former inhabitants of our coast; they exist in great number, and some of them are now to be found at a distance of several miles from the sea-shore, though originally they were, of course, built near the spot where the shells lived. Some are of considerable size; we were told that a Sambaqui on a little island near San Francisco had a height of about 100 metres; but the largest I have seen myself did not exceed 10 or 12 metres. As to the shells of which they are composed, the Sambaquis may be divided into three classes, viz.: (1) Sambaquis, consisting of many different species of bivalve and univalve shells (Venus, Cardium,

[1] We observe that our author says that these were first used by Lord Brounker; it has been shown that Cataldi has a prior claim to this distinction.

Lucina, Arca, Ostrea, Purpura, Tritonium, Trochus, &c.), all of which are at present living in the neighbouring sea. (2) Sambaquis, consisting almost exclusively of a small bivalve shell, the "Birbigãs" of the Brazilians (*Venus flexuosa?*), exceedingly common in shallow bays or salt-water lagoas, the bottom of which is of mixed mud and sand. (3) Sambaquis, consisting exclusively of a species of Corbula, which I have not yet seen in a living state; all the Brazilians also, whom I asked, and who are perfectly acquainted with any edible animal of their marine fauna, are unanimous in affirming that this shell does not live now on our coast. From one of these Corbula-Sambaquis I obtained a specimen of a small Melampus, which I have found living near the mouth of some rivulets, where fresh and salt water are mingling in ever-varying proportions. When the lowlands of the Lower Itajahy and some of its tributaries were as yet beneath the level of the sea, they would have formed a large estuary, and here probably the Corbulæ lived. The fragments of human skulls which we found in one of these Corbula-Sambaquis were of truly astonishing thickness, whereas those I have seen from other Sambaquis are hardly thicker than our own. Among the tools which are to be found in the Sambaquis, stone-axes are by far the most frequent. But as M. Wiener will probably soon publish a full account of his researches, I will now no longer dwell on this subject.

Some time ago I sent to Germany for publication a note on the relation between our Imbauba trees (Cecropia) and the ants which inhabit their hollow stem. As there may be some delay in publishing, I will give you a short abstract. Mr. Belt has already stated that the ants farm scale-insects in the cells of the Imbauba stem, and he believes that their presence must be beneficial. This is no doubt the case; for they protect the young leaves against the leaf-cutting ants (Oecodoma). Now there is a wonderful contrivance by which, as in the case of the "bull's-horn acacia," the attendance of the ants at the right time and place is secured. At the base of each petiole there is a large flat cushion, consisting of most densely-crowded hairs, and within this cushion a large number of small white pear-like or club-shaped bodies (specimens inclosed) are successively developed, which, when ripe, emerge at the surface of the cushion, like asparagus on a bed, and are then greedily gathered by the ants and carried away to the nest. The object of the dense hair-cushion appears to be (1) to secure to the young club-shaped bodies the moisture necesary for their development; and (2) to prevent the ants from gathering the unripe bodies. In most cases it is by honey-secreting glands that the protecting ants are attracted; now Mr Belt observed ("Nicaragua," p. 225) that the honey-glands on the calyx and young leaves of a Passion-flower were less attractive to the ants than were the scale-insects living on the *stems;* this would most likely be the case with the Imbauba, and it is probable that the use of the little pear-shaped bodies is to form an attraction stronger than that of the scale-insects, and thus to secure the attendance of the protective ants on the young leaves. As far as I could make out, the club-shaped bodies consist mainly of an albuminous substance. The ant colonies are founded by fertilised females, which may be found frequently in the cells of young Imbauba plants. Each internode has on the outside, near its upper end, a small pit where the wall of the cell is much thinner than anywhere else, and where the female makes a hole by which she enters. Soon after this the hole is completely shut again by a luxuriant excrescence from its margins, and so it remains until about a dozen workers have developed from the eggs of the female, when the hole is opened anew from within by these workers. It would appear that the female ants, living in cells closed all around, must be protected against any enemy; but notwithstanding a rather large number of them are devoured by the grub of a parasitic wasp belonging to the Chalcididæ; Mr. Westwood has observed that the pupæ of the Chalcididæ exhibit a much nearer approach to the obtected pupæ of the Lepidoptera than is made by any other Hymenoptera" ("Introd. to the Modern Classif. of Insects," Part XI., p. 162). Now the pupa of the parasite of the Imbauba ant is suspended on the wall of the cell by its posterior extremity just like the chrysalis of a butterfly.

I hope you will have received a paper on Æglea, a curious Decapod inhabiting the mountain rivulets of our Serra do Mar. Lately I obtained a large number of specimens of this Æglea, and among them a female with eggs in an advanced state of development. Thus I was enabled to satisfy myself that, like so many fresh-water and terrestrial animals, the marine allies of which undergo a transformation, our Æglea does not experience any metamorphosis. FRITZ MÜLLER

Itajahy, St. Catharina, Brazil, Dec. 25, 1875

Prof. Tyndall on Germs

YOUR able correspondent "Inquirer" would hardly blame Horatius for taking his enemies one at a time. May I not, then, claim his indulgence for following, in an extremely humble way, the example of the gallant Roman? He may accept my assurance that during the last five months I have found Dr. Bastian quite enough for me.

Moreover, I do not think it likely that Dr. Sanderson and myself will ever cross swords upon this question. Our relation, I am happy to think, will be one of co-operation, not of antagonism. The experiments on pure infusions, not those on mixtures of solids and liquids, to which "Inquirer" directs my attention (NATURE, vol. vii., p. 180), are, in my opinion, too scanty, and too little in harmony with each other, to bear an inference of any weight. To Dr. Sanderson I prefer leaving the repetition of them, with the full confidence that the ability and candour for which he is so distinguished will lead him to a right result.

In repeating these experiments, it would, I think, be well to bear in mind the remarks of Dr. Roberts (NATURE, vol. vii., p. 302), however unimportant they may seem to Dr. Bastian. I would also suggest the substitution, in boiling, of an oil-bath for the Bunsen burner, and, in sealing, the abandonment of the blow-pipe and the use of the simple spirit-lamp flame.

Experiments on milk and pounded cheese are, it may be observed, at present beside the mark. They shall be subjected in due time to the scrutiny already bestowed upon really liquid infusions. It ought not to be forgotten that the jungle we have entered has been growing umbriferously for the last six years, and it is only bit by bit that the sunlight can be let in upon it.

"Inquirer" may count on my sympathetic readiness to minister, however humbly, to the delight he takes in following "every investigation which tends to the development of science." If he cares to see my infusions, it will give me great pleasure to show them to him. Condensed abstracts only of my investigation have been laid before the Royal Society and the Royal Institution; a fuller account of it will follow by and by. Meanwhile, I hope "Inquirer" will accept the assurance that I have been strict—I might say abject—in my adherence to the conditions prescribed by Dr. Bastian in his books. JOHN TYNDALL

Heathfield, Feb. 13

[The following letter has been sent us for publication by Prof. Tyndall.—ED.]

PERMETTEZ-MOI de vous dire combien je suis charmé que vous apportiez dans la question de la génération spontanée la grande autorité de votre esprit philosophique et de votre rigeur expérimentale. C'est tout à la fois un honneur pour mes recherches et une vive satisfaction personelle que les conclusions auxquelles vous êtes arrivé s'accordent si bien avec celles de mes propres travaux, malgré la différence des méthodes que nous avons suivies. Le tour piquant que vous avez su donner à vos expériences les fera pénétrer plus avant que les miennes dans l'esprit de tout lecteur que n'égarent pas les idées *à priori.*

Dans le numéro du 5 février courant du *British Medical Journal* le docteur Bastian accepte sans réserve l'exactitude de toutes les expériences de mon mémoire de 1862 (*Annales de Physique et de Chimie*).

Il accepte également, sans nul doute, les resultats de celles que j'ai publiés en 1863 et en 1872 sur le sang, sur l'urine, sur le jus intérieur des grains de raisin, exposés, dans l'état même où la vie a formé ces liquides complexes, au contact de l'air pur,

privé de ses poussières flottantes. Dès lors je dois appliquer au docteur Bastian ces paroles de mon mémoire de 1862, pages 70 et 71 : "En présence de ces résultats (résultats que je viens de rappeler et qu'accepte le docteur Bastian), un partisan de la génération spontanée veut-il continuer à soutenir ses opinions? Il le peut encore ; mais alors son raisonnement sera forcément celui-ci : 'Il y a dans l'air, dira-t-il, des particules solides, telles que carbonate de chaux, silice, suie, brins de laine, de coton, fécule . . . et à côté, des corpuscules organisés d'une parfaite ressemblance avec les spores des mucidinées ou avec les kystes des infusoires. Eh bien, je préfère placer l'origine des mucidinées et des infusoires dans le premiers de ces corpuscles, ceux qui sont amorphes, plutôt que dans les seconds.'" L'inconséquence d'un pareil raisonnement ressort d'elle-même et le progrès de mes recherches consiste à y avoir acculé les partisans de l'hétérogénie. Lisez attentivement l'article précité du docteur Bastian et vous verrez qu'il se résume en effet, dans le raisonnement que je viens de reproduire. Le docteur Bastian me permettra de placer dans sa bouche ces paroles :—"C'est bien vrai, les expériences de M. Pasteur et celles de M. Tyndall m'ont acculé, moi Docteur Bastian, partisan de la génération spontanée, dans cette déclaration. Oui, je préfère recourir sans motif sérieux, à la croyance à une force résidant dans la partie amorphe des poussières en suspension dans l'air plutôt que de la placer cette force dans la partie organisée formée de corpuscules identiques d'aspect à ceux des germes des organismes des infusions." Parler ainsi n'est-ce pas avouer sa défaite?

Quelles sont donc ces particules amorphes dont vous invoquez si gratuitement l'influence et de quel droit leur attribuez-vous les *primum movens* de la vie? Pourquoi, si vous aviez raison, ne le trouverait-on pas ce *primum movens* dans les particules amorphes ou organisées qui existent à l'etat naturel dans le sang frais, dans l'urine fraîche, dans le jus du raisin, quand on expose ces liquides dans l'air pur? Voulez-vous que vos particules amorphes, douées du *primum movens* de la vie des infusions, sortent de matières déja alterées, putrides, etc. . . . . mais, pourquoi seraient-elles chariées par l'air sans être accompagnées des germes et des êtres vivants de ces infusions et, s'il en est ainsi, comment ne pas placer le *primum movens* de la vie dans ce qui est vivant, plutôt que dans ce qui n'a rien des caractères apparents de la vie?

Elle est inattaquable, cette conclusion que j'ai déja formulée : *dans l'état actuel de la science, l'hypothèse de la génération spontanée est une chimère.* Votre bien dévoué,

Paris le 8 Fevrier, 1876 L. PASTEUR

Mr. Sorby on the Evolution of Hæmoglobin

IN the short notice in NATURE (vol. xiii. p. 257) of my paper on the Evolution of Hæmoglobin, in the *Quarterly Microscopical Journal*, it is said that my conclusions are mainly based on a small difference in the wave-length of the absorption-bands of the spectrum of the red blood of *Planorbis*. This is, however, a very small part of the question. The principal results are that hæmatin is first met with in the bile of many pulmoniferous molluscs in an abnormal state, quite unfit to serve the purposes of respiration, but easily changed into the normal, which could, and probably does in some cases, perform that function. Then in the blood of *Planorbis* we have a *solution* of a hæmoglobin, in which the hæmatin is combined with an albuminous constituent coagulating at the low temperature of 45° C., and finally we come to the normal hæmoglobin existing as *red corpscules*, containing an entirely different albuminous constituent, coagulated at about 65° C. In all these changes in the condition of the same fundamental radical, the oxygen carrier becomes of more and more unstable character, and more fitted for the purposes of respiration, as we advance from lower to higher types, as though advantage had been taken of every improvement due to modified chemical or physical constitution. H. C. SORBY

The Flame of Common Salt

IN answer to a question put by one of your correspondents (p. 287), allow me to state that the origin of the blue flame in question is still involved in mystery. Your correspondent will find everything that is known on the subject in a letter addressed to the editor of the *Philosophical Magazine*, by Prof. J. H. Gladstone (*Phil. Mag.* 1862, vol. xxiv. p. 417).

Prof. Schorlemmer and I are at present engaged in a joint investigation, which we hope will throw some light on the origin of the flame. We have already obtained interesting results, and observed the flame under circumstances in which it has not been seen before, but we are as yet entirely unable to say what the flame is really due to. ARTHUR SCHUSTER

Owens College, Manchester, Feb. 12

Science at Hastings

HAD we here a few more men like Mr. Alex. E. Murray, my paper on "Science at Hastings" would never have been written. But I fail to see in what way he has "vindicated the honour of Hastings." With the exception of one or two sentences which require qualification, his letter is simply an emphatic repetition of what I said in the Hastings and St. Leonards *News*. The substance of my paper may be given in one of its sentences: "With the exception of occasional debates among the members of the Philosophical Society and the few scientific lectures in the winter programme of the Mechanics' Institution, there is in Hastings no public encouragement or aid to science." As to the Philosophical Society, Mr. Murray admits that, "owing to a variety of circumstances, it is not at present quite so flourishing as we could wish." In point of fact, during the session 1874-75, four papers were read and a conversazione held. This Society is the only distinctively scientific one in the town, notwithstanding the "multiplicity" of institutions mentioned by Mr. Murray. Popular scientific lectures are occasionally given in connection with various associations for young men; and the Mechanics' Institution also has a winter lecture session, but unfortunately the Committee find it very difficult to obtain lecturers, and are fain to eke out their list with musical evenings and readings. The Literary and Scientific Institution has for many years dropped the word "Scientific" from its name, and at present seeks merely to provide for a few of the older inhabitants of the town a quiet reading-room supplied with papers, a few reviews and magazines, and a box from Mudie's. Scarcely a new book has been bought for very many years. The meteorological instruments which the Institution "formerly possessed" were, with the exception of the barometer, broken long ago, and the barometer has since been sold. At one time—twenty years ago—I was in the habit of taking the observations in the absence of the gentleman whose special business it was; but it must be at least a dozen years since any observations were systematically taken.

In conclusion, I claim to have fully recognised in my paper all that is being done in Hastings in the interests of science, and I sincerely regret that Mr. Murray has not been able to discover any omission on my part. We have no museum, we have no public library in which there are scientific books recent or numerous enough to be of any use to a student, except in a school or two; we have no Naturalists' or Field Clubs; with the exception of the Philosophical Society, all the existing institutions in Hastings have practically lost what scientific character they may at one time have possessed; and the Philosophical Society itself is neither exclusively scientific nor exclusively local in its aims, and is unfortunately "not quite so flourishing" as could be wished. ARTHUR RANSOM

Hastings, Feb. 5

OUR ASTRONOMICAL COLUMN

THE VARIABLE STAR R LEPORIS.—This highly-coloured star, the variability of which was detected by Schmidt in 1855, is calculated to be at a maximum on the 28th of the present month. The mean period appears to be about 438 days, 230 days being occupied in passing from minimum to maximum, and 208 days from maximum to minimum. Probably the irregularities of variation which have been suspected are to be mainly attributed to the difficulty attending comparisons of a star of such intensely red colour. With regard to the colour, however, there is something more than a suspicion that it has sensibly diminished in intensity since attention was first directed to it (Hind, 1845, October). We are almost wholly indebted to Schmidt, who makes such excellent use of the favourable astronomical conditions under which he is placed at Athens, for our knowledge of the law of variation in R Leporis.

SATURN'S RINGS.—In the last (January) number of the "Monthly Notices of the Royal Astronomical Society" are reproduced some old drawings of Saturn, given in the edition of Gassendi's works published at Lyons, in six volumes, in 1658 (Lalande, *Bibliographie Astronomique*, p. 245).

In the volume entitled *De Annulo Saturni*, by E. M. Beima (Augsburg, 1842), a work less known in this country than it deserves to be, will be found other reproductions of the earlier drawings illustrating the appearances which the planet was thought to present in the imperfect telescopes of the time. As a pretty complete monograph up to the date of publication, involving an exposition of the formulæ required in calculating the various phases of the rings, &c., Beima's treatise will be found a very desirable addition to an astronomical library.

THE MINOR PLANET, HILDA (No. 153).—In Herr Kühnert's last orbit of this planet, the aphelion distance is found to be 4·595, and the heliocentric latitude in aphelion, $-6^\circ 33'$, the longitude at this point being $105^\circ 1'\cdot 6$; hence, the least distance of the planet from the orbit of Jupiter is reduced to 0·564 of the earth's mean distance from the sun. So near an approach might afford an excellent opportunity of determining the value of Jupiter's mass, but if the period of revolution assigned by Kühnert upon eight-weeks' observations is at all approximate, such opportunity will not occur for many years to come. There may be a difficulty in recovering this planet at the next opposition, which is likely to take place near the aphelion, and when its faintness, owing to great distance from the earth, will be considerable; it is the more desirable, therefore, that observations should be obtained in the next period of absence of moonlight, that the mean motion may be fairly determined this season; the Ephemeris published in No. 2,075 of the *Astronomische Nachrichten* should render the identification of the planet a matter of no great difficulty in instruments of adequate aperture.

From the *résumé* of observations in No. 42 of the Circulars of the *Berliner Astronomische Jahrbuch*, it appears that No. 149 may get adrift, unless an observation on Nov. 2 can be proved to belong to it, and No. 155, as already remarked, is in even worse position.

THE TOTAL SOLAR ECLIPSE OF 1706, MAY 11–12.—Calculating upon the same system as employed for the solar eclipses to which reference has already been made in this column, the following elements result for the eclipse of May 1706, extensively observed in France, &c.

Conjunction in R.A. 1706, May 11, 21h. 59m. 26s. G.M.T.

R.A.	48°	40′	27″
Moon's hourly motion in R.A.		36	49
Sun's " " "		2	50
Moon's declination	18	42	52 N.
Sun's "	18	4	0 N.
Moon's hourly motion in decl.		13	9 N.
Sun's " " "		0	36 N.
Moon's horizontal parallax		60	35
Sun's " "			9
Moon's true semi-diameter		16	31
Sun's " "		15	49

The following are points upon the central track of the shadow:—

Long.	Lat.		Long.	Lat.
5° 40′ W.	34° 39′ N.	...	16° 32′ E.	52° 23′ N.
1 4 E.	40 40	...	20 2 E.	54 20 N.
4 18	43 29	...	Central at Apparent Noon in Long. 29° 7′ E. Lat. 58° 18′ N.	
7 37	46 12 N.	...		

For examining the circumstances of the eclipse in the South of France, where the totality was witnessed, we have the following reduction equations founded upon a direct calculation for Avignon:—

$$\text{Cos. } w = 41\cdot 1909 - [1\cdot 72518] \text{ sin. } l + [1\cdot 59372] \text{ cos. } l, \text{ cos. } (L - 103^\circ 46'\cdot 3)$$
$$t = 21\text{h. } 26\text{m. } 5\cdot 8\text{s.} \mp [2\cdot 08389] \text{ sin. } w + [3\cdot 60351] \text{ sin. } l - [3\cdot 84024] \text{ cos. } l, \text{ cos. } (L + 38^\circ 1'\cdot 4).$$

In these equations L is the longitude from Greenwich reckoned *positive* to the *eastward*, l the geocentric latitude, and t the *Greenwich* mean time of beginning or ending of totality, according as the upper or lower sign is used.

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA [1]

I.

IF no certain *consensus* has yet been arrived at as to what palæontology teaches in reference to the derivative hypothesis, the chief reason is our very imperfect knowledge of palæontology, arising partly from the necessary imperfection of the geological record caused by the very small chance of the remains of any creature living upon the earth being preserved in a perfect state; partly from the very minute portion of the record which is actually preserved in the rocks having as yet been rendered accessible to investigation; partly from the defective knowledge of the structure and relationship of those documents, so to speak, which have already been brought to light, and of their existing representatives. The first cause must always remain a stumbling-block to these investigations. The second is gradually being removed by fresh explorations in many parts of the world, notably those now carried on with so much energy and success in North America. The third is one which only needs more numerous and more earnest workers to remove, and especially those who have the power and will to see the continuity of the manifestation of life upon the earth, and will abandon the old practice of studying the fauna of a particular epoch apart from that which preceded or succeeded it, and especially that of studying extinct forms without a thorough mastery of the key to the solution of the difficulties of their structure afforded by the more accessible existing species. Palæontology is no science apart—it can scarcely even be called a branch of zoology; it is simply the application of that science to elucidating the structure of beings now extinct. The thoroughly unscientific and mischievous system of arrangement of nearly all our great public museums, both at home and abroad, where two distinct collections are kept up, under distinct custodians—one for animals existing at the present moment upon the earth, and the other for animals that have existed at all other periods put together—has much to answer for in impeding the progress of sound zoological knowledge. Granted that our information is of a very limited nature, it still seems worth while occasionally to gather together the fragments of which it consists; and as it would be impossible in the time allotted to this course to do justice to more than a limited portion of the whole animal kingdom, it is proposed to take the class of mammals, as in many ways well suited for testing whether such facts as are known of their ancient history throw any light upon their mode of origin, and to point out, with impartiality, the results of the investigation. The poverty of the materials in some quarters, as well as their abundance in others, will thus be made manifest, and some useful landmarks afforded which may direct and stimulate future research.

As far as we know of the existing fauna of the world, and we can hardly suppose that in this respect our knowledge is not final, the Mammalia constitute a clearly defined group or class of the Vertebrata. Though covering a wide range of variety in structure, scarcely any zoologist has ever had any hesitation in defining its limits. There are, however, certain forms decidedly aberrant, and which in many of the characters in which they deviate from the ordinary standard of the class, approximate to the lower groups of vertebrates. The most marked examples of

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.)

this condition are seen in the Marsupials, and in a still higher degree in the small order of Monotremes. These present a marked approach to the *Sauropsida*, or reptile and bird group. Such semi-transitional forms, as they may be called, furnish valuable indications of the route by which the higher types might have been brought about, and appear, upon the evolutionary hypothesis, to be unmodified survivors of a condition which was only transitory in the large bulk of the class. Their value as evidence for gradual development would be greatly strengthened if corroborated by palæontology. Beyond them nothing is known in the present condition of life of any truly intermediate forms between the Mammalia and the other class of vertebrates, and the same must be said, as far as we know at present, of all former ages. The line which we now draw round the class to separate it from all others will include within its limits all hitherto discovered mammalian remains. No forms more transitional, or approaching nearer to any other class, or even, as we shall see, so near as do the Monotremes, occur in the records of palæontology. Of course our evidence on the subject is only negative, and as such has little real value. The first appearance, of which we are at present informed, of mammals upon the earth, was early in the Mesozoic period, in the epoch called Triassic. At that time the other classes of Vertebrata, except, perhaps, birds (but our evidence here is defective), had long been well established and distinctly defined. Indications of mammalian life occur in various formations, at different ages, and at scattered points upon the earth's surface, throughout the Mesozoic ages, but during its later stages are entirely lost. These indications, though very fragmentary, all show animals of minute proportions, and for the class to which they belong, rather low organisation. With the commencement of the Tertiary period, however, a total change takes place. Wherever the great Cretaceous ocean bottoms have been elevated so as to become the fit habitation of terrestrial animals, there mammals of varied size, form, and function have been found to dwell, and have left their remains, and from henceforth to the present time there is abundance of evidence of their continuous occupation of the earth's surface. The total absence of all marine mammals in the Cretaceous epoch, the fauna of which is, on the whole, so well preserved, and the absence of land mammals in the Wealden, are facts, which though difficult to account for, must not be overlooked.

Before proceeding to the consideration of the history of the special groups of Mammalia, attention may be called to a few points of general interest relating to the whole class, in which palæontological researches appear to have shown some evidence of gradual modification or progression as time advanced. The first is a small point, as it relates only to one family of animals, but it affords a good illustration of the parallelism which has been observed between the development of the race and that of the individual. The earliest known forms of deer, those of the Lower Miocene, as remarked by Gaudry, have no antlers, as the young of the existing species. The deer of the Middle Miocene have simple antlers, with not more than two branches, as in existing deer in the second year. In the Upper Miocene, species occur with three branches to the antlers, but it is not until the Upper Pliocene and Pleistocene times, that deer occur with antlers developed with that luxuriance of growth and beauty of form, characteristic of some of the existing species in the perfectly adult state. Next, the teeth in the greater number of Eocene mammals, both herbivorous and carnivorous, were of a much more generalised character than at present, and, as shown by Owen, commonly presented the full typical number of three incisors, one canine, four pre-molars, and three molars in each side of each jaw, making forty-four in all, a number found only in two genera at present existing. These teeth, moreover, in many species were more uniform in character and regularly placed, without intervals, in the jaws than in most of the later forms. They were also usually very short-crowned, and many cases can be traced of a successive lengthening of the crowns of the molars, and consequent greater provision for the wear of the organ, in a closely allied series of animals passing through successive geological epochs. Lastly, as remarked first by Lartet, and subsequently by Marsh, there has been in many groups a gradual increase of the size of the brain, as ascertained by the capacity of the interior of the cranium. Most of the Eocene mammals had very small brains in proportion to their size; this is well exemplified in the earliest known European Eocene carnivorous mammal, *Arctocyon primævus*, and still more strikingly in the huge American *Dinocerata*, animals nearly as large as the existing elephants, but whose brain cavity more resembles that of a reptile, being not more than one-eighth the capacity of that of a rhinoceros. The Miocene mammals of the same country had better developed brains, but even in the Pliocene Mastodons they did not equal the existing Proboscidea. A similar progression of brain capacity has been observed among deer, among the tapiroid Ungulates, and in a very well marked manner among equine mammals, especially from the Eocene *Orohippus*, through *Miohippus* and *Anchitherium* of the Miocene, *Pliohippus* and *Hipparion* of the Pliocene, to the recent *Equus*.

(*To be continued.*)

MADAGASCAR[1]

As most probably many of our readers know, a wealthy Parisian, M. Alfred Grandidier, who is thoroughly acquainted with Madagascar in all its aspects, has undertaken a mighty work on the physical, natural, and political history of the island, which is to form, when completed, twenty-eight volumes in large quarto, profusely illustrated with coloured plates. Six volumes, three of text and three of plates, are to be devoted to the Mammals, the first of each of these being those under notice on the present occasion. They, together with the Birds, in three volumes, and the Crustacea, are under the editorship of M. Alph. Milne-Edwards. The Fishes are undertaken by Dr. Sauvage; the Reptiles by M. Grandidier; the Insects by MM. Kunckel d'Herculais, Lucas, Oustalet, De Saussure; the Annelids by M. L. Vaillant, and the Mollusca by MM. Fisher and Crosse.

In the volumes before us there are 122 plates devoted to the anatomy of the Lemurian family *Indrisinæ*. *Propithecus diadema*, *P. edwardsii*, *P. verreauxii*, *P. deckenii*, *P. coquerelii*, *P. coronatus*, *Avahis* (*Microrhynchus*) *laniger*, *Indris brevicaudatus* are the species figured. Of these plates, thirty-nine refer to their osteology, more than twenty to their myology, forty to their visceral anatomy, thirteen to their external form, and twelve (as photographs) to the configuration of the feet. Most of these plates are exquisitely coloured, and all are beautifully drawn; the livers being the only organs with which we have any fault to find. The volume of letterpress only extends as far as the myology, the account of the viscera not having yet appeared. It is to do so in March next. From the drawings alone many particularly instructive facts may be learnt. The colic caecum of *Propithecus* is seen to be comparatively short and capacious, at the same time that the helix formed by the convolutions of the colon itself is as considerable as in any ruminant animal. In *Avahis* the helix is much less developed, whilst the caecum is longer. In *Indris* the caecum is enormously long, not being wide, the colic coil not forming a helix, but being disposed in parallel

[1] "Histoire Physique, Naturelle et Politique de Madagascar." Publiée par Alfred Grandidier. "Histoire Naturelle des Mammifères." Par MM. Alph. Milne-Edwards et A. Grandidier. Vol. VI. (texte) et Vol. IX. (atlas). (Paris: Imprimerie Nationale, 1875)

transverse rows. The liver of *Avahis* is represented without any gall-bladder (it may be embedded), this viscus being large, and having, as in the typical lemurs, its fundus reversed from its ordinary position, and buried in the hepatic issue in the two other genera. The caudate lobe of the liver is absent, and the spigelian is of fair size. These points, it may be mentioned, have been previously recorded by Prof. Flower in his Hunterian Lectures before the College of Surgeons in 1872, on the visceral anatomy of the Mammalia. In *Propithecus* the left subclavian artery is shown to be given off from the innominate trunk, whence spring the three other main anterior vessels, whilst in *Avahis* and *Indris* it springs independently from the aorta. As in the other Lemurs and the Swine, the mesenteric arteries run straight to the walls of the viscera they supply, and do not form loops just before they reach them; they anastomose freely at their origins.

M. Milne-Edwards gives as the dental formulæ of the Indrisinæ the following:—

Milk dentition . . . $i\ \frac{2}{2}\ c\ \frac{1}{1}\ m\ \frac{2}{3} = 22$

Permanent dentition . $i\ \frac{2}{2}\ c\ \frac{1}{0}\ pm\ \frac{2}{2}\ m\ \frac{3}{3} = 30$

Whether or not this method of expressing the dentition is correct is a matter of uncertainty, it depending on the nature of the outer lower cutting teeth of the typical Lemurs. We cannot, with many zoologists, help retaining the opinion that the outer lower incisor-like teeth of *Lemur* and its nearest allies are canines, and they most certainly represent the outer pair in *Indris*, in which they are larger than the inner. The presence of a third lower milk molar confirms the opinion expressed by Prof. Huxley[1] in his memoir on the Angwántibo (*Arctocebus calabarensis*), that in the adult Indrisinæ it is a premolar which is missing in each semi-jaw.

M. Milne-Edwards gives elaborate measurements of the bones of the three genera, which are also represented in the graphic form, on ordinates, by which means excellent comparisons can be made at a glance.

In the myological section of the work, the contributions by Vrolik on *Stenops*, Messrs. Mivart and Murie on *Nycticebus* and the Lemuroidea generally, Van Campen and Van der Hoeven on the Potto, Burmeister on *Tarsius*, and Prof. Owen on the Aye-Aye are employed for comparison, and the whole monograph has filled the only important gap, till now vacant, in our knowledge of the anatomy of the Lemurs.

SCIENCE AND ART IN IRELAND

AN important announcement as to the proposed action of the Government with regard to the various scientific institutions in Dublin is contained in the following article, which we reprint from the *Times* of Tuesday last:—

The subject of the administration of Science and Art in Ireland in connection with increased State aid has now been under discussion at different times for many years. It must not be imagined, however, that Ireland is not already provided with numerous institutions for the promotion of Science and Art, or that it lacks grants for that purpose. In Dublin alone there are under the management of the Royal Dublin Society, which is a chartered body, a Museum of Natural History, Botanic Gardens (with Botanical Museum), and a library. Next comes a purely national institution, the Royal College of Science, with its small industrial collections and the geological collections of the Geological Survey. On the borderland of Science and Art we have the Royal Irish Academy, with its library and Antiquarian Museum, containing the richest collection of Celtic antiquities existing out of Copenhagen, including the celebrated Tara Brooch and Tara "torques," and the Cross of Cong.

Coming to the region of Art pure, we have the School of Art, under the management of the Royal Dublin Society; the Royal Hibernian Academy, corresponding to our own Royal Academy (which also has its School of Art); and lastly, the Irish National Gallery. So far as we can gather from the estimates, the total grant to Science and Art Institutions in Dublin is upwards of 25,000*l.* a year, though it is difficult to obtain very precise information on this head, as the votes are taken, some by the Science and Art Department, some by the Treasury, and some by the Office of Works.

The Library, the Natural History Museum, and the Botanic Gardens have since 1865 been entirely supported by the State, though managed by the Dublin Society acting as trustees, while the collections of the Royal Irish Academy, which receive an annual subsidy of about 2,000*l.* besides a house, have been very largely purchased out of public funds. The Royal Dublin Society has of late years devoted its energies and its private funds most usefully in furtherance of agriculture. The Royal Irish Academy not only covers the field of the Royal Society of England, but also takes under its care literature and antiquities.

It will thus be seen, to compare the State supported institutions in Dublin with those in London, that the elements of the British Museum, the Geological Museum, the South Kensington Museum, the National Gallery, and Royal Academy exist in Dublin, to say nothing of the Royal College of Science, which has a more complete course than our own School of Mines. In spite, however, of the number of these institutions, and, in fact, because of their number, the collections, whether of books, natural history specimens, or antiquities, have not had the completeness which one would expect. While on the one hand many have been inconveniently housed, on the other the Government has naturally felt a difficulty in improving their condition so long as they were in the hands of more or less irresponsible private bodies, and hence the many attempts to bring about a consolidation, to which we may briefly refer.

Thus we find that in 1862 the Treasury appointed a small Commission, with Sir C. Trevelyan as chairman, which made certain recommendations. Before these were acted on, however, the subject was, in 1864, taken up by a Committee of the House of Commons, of which Mr. Gregory was chairman. This body dissented widely from the views expressed by the Treasury Commission, and thus the matter rested till 1868, when the Government decided to constitute a separate Department of Science and Art for Ireland, "analogous in its constitution to the existing Science and Art Department in London for the United Kingdom;" and appointed a Committee, of which the Duke of Leinster, then Marquis of Kildare, was chairman, to report on the best means of carrying out the project.

The Committee, having upon it such representative Irish members as the Marquis of Kildare, the Very Rev. Dr. Russell, the then President of Maynooth, the Rev. S. Haughton, and Mr. G. A. Hamilton, the then Secretary of the Treasury, soon found it impracticable to organise such an independent department as had been contemplated, and applied for an enlargement of their instructions; in fact, it became evident very early in the inquiry that all but a small minority in Ireland were in favour of continuing the connection with the English Department. Teachers and students specially petitioned that the connection might be maintained, as they saw clearly that the severance would deprive them of the highest rewards and best promises of a career by cutting off the English field from them. However much some may regret the fact, the fact remains that in all vocations the highest talent will seek the place where it is most highly prized and rewarded, which in the case of the United Kingdom means London.

Acting upon this and other considerations, to which we need not further allude, the Commission unanimously came to the conclusion that the remedy they were seeking lay, not in the formation of a separate Department for Ireland—which, indeed, they went on to say would be detrimental to the interests of Science and Art in that country—but in the consolidation and better administration of the existing institutions, and in the filling up of some obvious gaps. The essence of their recommendations was the amalgamation of several of the collections into an institution strongly resembling the South Kensington Museum, but covering a wider field, which should be administered by a director, who should be in immediate relation not only with the Minister of Education, but also with the Irish Government. This scheme, however, had a great drawback in the eyes of many of the leading noblemen and gentlemen in Ireland who were interested in the existing institutions, because it entailed the deprivation in the case of the two principal societies —the Royal Dublin Society and the Royal Irish Academy —of the privileges they had hitherto enjoyed of administering large public funds voted for the Natural History Museum and the Botanic Gardens, as well as other institutions. This objection and, possibly, the economical views of the late Government, have sufficed to keep this question in abeyance since 1868; but it now appears that the present Government have determined to take some decided step, for they have, we understand, during the last few days communicated with the bodies principally interested in the scheme.

From the information which has reached us we gather that the plan now proposed is as complete as that indicated by the Commission of 1868, although it is not identical with it. Thus it has been decided to build a Science and Art Museum for Ireland similar to that now existing in Edinburgh. This will occupy a site adjacent to the principal buildings which now exist, and will consist of collections analogous to those of the South Kensington Museum, to which will be added the antiquarian collection of the Royal Irish Academy, and the industrial collection of the old Museum of Irish Industry. The building will also provide space for the Natural History Museum and Geological Collection, and will thus set free the present Natural History Museum, to which the library of the Royal Dublin Society will be transferred and formed into a public National Library.

As may be imagined, this comprehensive scheme will entail the expenditure of a large amount of public money, and the Government make the offer contingent on the surrender of the privileges to which we have before referred, and the vesting of all the property in the Government. With the view, however, of still enabling those who at present take so great an interest in the existing institutions to continue this useful co-operation and represent the special wants of the country, it is proposed that the new National Library shall be managed by a Council of twelve trustees—eight to be nominated by the Royal Dublin Society and four by the Government; while the administration of the Science and Art Museum, which is to be under a director appointed by the Crown, as in Scotland, will be controlled by a Board of twelve visitors—four nominated by the Lord Lieutenant; five by the Royal Dublin Society; and three by the Royal Irish Academy.

It is not proposed to interfere with the functions of the societies we have named, and we are glad to see that the Government propose still to continue the aid they now give to them.

In making these proposals the Government has taken the opportunity of putting on record its appreciation of the eminent services which have been rendered to both art and science by the societies we have named, and makes it clear that the motive for suggesting any diminution of their independence is, that the wants of the community with regard to such matters as public museums have now in Ireland, as long ago in England, outgrown the useful operation of private societies.

The surrender of what we may, we hope, without offence, term some of their ornamental functions, will no doubt be somewhat painful to their members; but we cannot suppose that they will allow their private feeling to stand in the way of a national scheme so rich in promise, and based on principles which we should be glad to see applied in other localities besides Dublin.

MINIATURE PHYSICAL GEOGRAPHY

THE sands of the Lower Bagshot series are exposed along the shore at Bournemouth and form the cliffs. They are agglutinated into a very friable sandstone, which

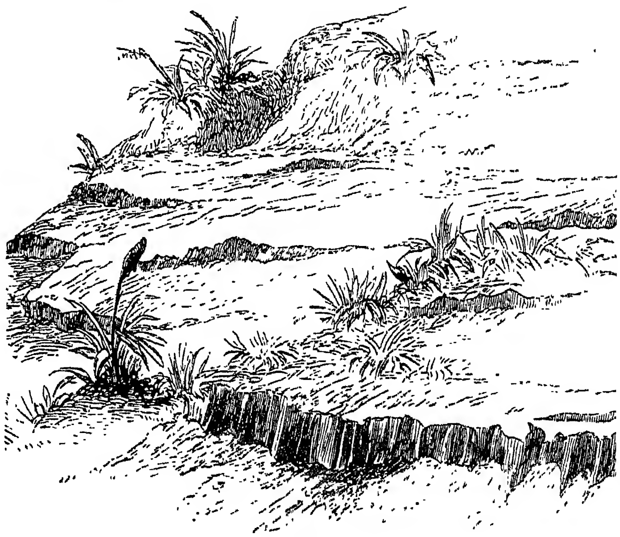

FIG. 1.

disintegrates under the influence of rain with extreme readiness. The siliceous grains are cemented together, probably by carbonate of lime. At any rate the adhesion of particle to particle is very slight and easily relaxed.

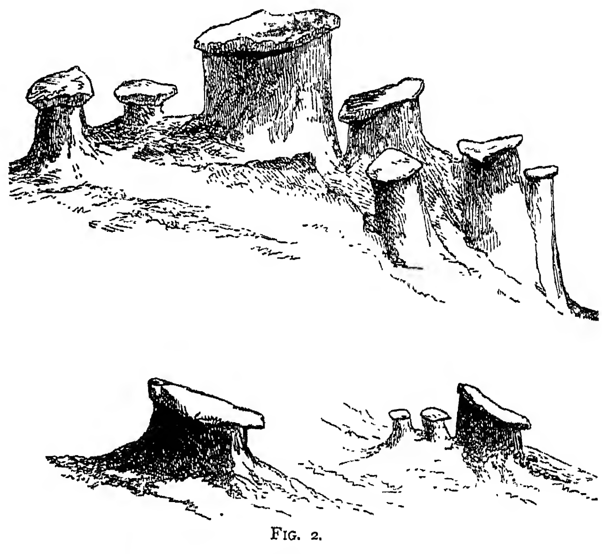

FIG. 2.

The result is that phenomena of erosion which elsewhere take years, centuries, ages, display themselves here on a miniature scale, and in a very short space of time. All the details of a river drainage system may be seen

with perfect completeness in the space of a few square yards. Watersheds bounding contiguous basins, gently sloping plains, deeper valleys, steeply cut ravines may be recognised according as the rock varies here and there in more or less of cohesiveness.

The slight inequalities in this respect give rise to many other details worth noticing. On the vertical surface of the cliffs the rock is etched in a manner scarcely perceptible unless the sun shines obliquely on its surface. In this way a rock apparently homogeneous is seen to have been originally built up of layers deposited at the most various angles in the manner characteristic of what is called false bedding.

Here and there an undisturbed talus at the foot of a cliff has been permeated by water carrying some cementing material which feebly binds together again the incoherent sand. The base gets washed or blown away, and the surface of the talus is seamed with miniature landslips leaving steep and precipitous cliffs of the frightful height of at least two to three inches. These precipices are scored and columned with the sharpest fluting as they have been planed down by the subsiding soil (Fig. 1 reduced).

Here and there again the rock is traversed horizontally by layers, in which the cementing material is ferruginous. When the rock is denuded down to this it first gets washed pretty bare and then broken up into angular fragments by the frost. Each of these fragments protects the rock beneath, and so gradually gets mounted upon a little pedestal like the perched blocks of a Swiss glacier or the mud columns in the valley of Visp (Fig. 2, natural size). T. D.

PHYSICAL SCIENCE IN SCHOOLS

THE struggle which Physical Science has had to obtain a footing amongst the regular subjects of the school curriculum has not been altogether in vain, and the study of science now occupies a conspicuous place in the prospectus, at any rate, of many of our schools. But to those who, being behind the scenes, are acquainted with the real facts, the position which science occupies amongst other subjects, with a few honourable exceptions, is insignificant in the extreme. It is admitted as an axiom by all science teachers, that if the study of science is to be of any value, the student must, in some part at least of his work, be brought face to face with the facts of nature, and that unless this be the case the introduction of the subject into the school course is worse than useless; but how commonly does the so-called science-work of a school consist simply in the acquisition of so much "useful knowledge?" And even when in other respects the teaching is fairly satisfactory, the practical work is too often optional—an "extra," or taken on half-holidays, and so ruined by the competition of cricket and football.

We believe that a fair standard by which to judge of the present position of the study of science in schools is to be found in the "Regulations of the Oxford and Cambridge Schools Examination Board," and in the papers set at the examination for certificates (the first held) of July 1874. Certificates are awarded to those who succeed in passing in a certain number of subjects; and the possession of such a certificate should indicate that a boy has obtained a thorough education up to the point fairly to be expected on leaving school.

Regulation 7 provides that "the examination for certificates shall include the following subjects:—

"GROUP I.—(1) Latin; (2) Greek; (3) French and German.

"GROUP II.—(1) Mathematics (Elementary); (2) Mathematics (Additional).

"GROUP III.—(1) Scripture Knowledge; (2) English; (3) History.

"GROUP IV.—(1) Natural Philosophy; (2) Heat and Chemistry; (3) Botany; (4) Physical Geography and Elementary Geology.

Every candidate shall be required to satisfy the examiners in at least four subjects, taken from not less than three different groups."

From the foregoing Regulation, one would naturally suppose that equal value was attached to each of these subjects, an arrangement which would leave no room for the complaint that science did not receive its proper credit. Let us examine whether such is the case.

The examination papers show that out of more than fifty-two papers set, *only four* were set on scientific subjects. To pass in Latin it would seem that *five* different papers must be satisfactorily answered, in Greek *four*, in French and German *eight*, in Elementary Mathematics *three*, in Additional Mathematics *four*, in Scripture Knowledge *three*, in English *three*, in History *one*, in Natural Philosophy *one*, in Heat and Chemistry *one*, in Physical Geography *one*, in Botany *one*. We may not unfairly take these numbers as representing the relative value of the different subjects in the eyes of the compilers of the Regulations.

Thus, while a candidate who, having received his training in languages, selects, say Latin, French and German, English, and Elementary Mathematics, has to answer nineteen papers—the same certificate may be cheaply obtained from *seven* papers, by selecting Scripture Knowledge, Elementary Mathematics, Chemistry, and Physical Geography.

Next let us examine the kind of questions set. Elementary Mathematics means simply Arithmetic, Euclid, books i. and ii., and Algebra to simple equations. In Heat and Chemistry we find the following, amongst others (space does not permit to transcribe the whole paper).

1. Define "co-efficient of expansion." What relations subsist between the linear, superficial, and cubical expansion of a piece of iron?

2. Describe fully the successive changes which occur when a piece of ice is placed in an open vessel, and the vessel then gradually heated to, say, 150° C.

3. What are our available sources of heat?

4. What degrees on the Centigrade scale correspond to 16° R. and − 4° F.? At what temperature will Fahrenheit and Centigrade thermometers give the same reading?

5. Distinguish between elements and compounds, and between compounds and mixtures.

6. What is the composition of the atmosphere? Give the outlines of a method for analysing it accurately. How is it proved to be a mixture and not a chemical compound?

7. I want to convert 132·4 grm. of lead nitrate into lead sulphate. How much potassium sulphate will effect this change, and how much lead sulphate shall I obtain? (Pb = 207, K = 39.)

In Physical Geography:—

1. How may the earth be proved to be a globe, and in what respects does it differ in form from a perfect sphere?

2. Show by examples how climate is affected by the position of a locality independently of the latitude?

3. Define the terms *watershed, denudation*. Give instances of denudation effected by rivers.

4. Explain the terms *dip, strike, joints*, and *faults*.

5. What is supposed to be the origin of coal, and on what facts is this supposition based?

6. Name and describe fully the accompanying specimens:—

[Specimens: Granite, oolite, dolomite, selenite, and two bivalve fossils.]

It is to be remarked that, with the exception of the last question, there is no test of a practical kind at all. Is the knowledge of the composition of the air, of the reasons for believing that the earth is round, of the meaning of the terms *watershed, dip*, &c.—is this the utmost that should be demanded of a boy of eighteen who has studied science instead of the older well-established subjects of classics and mathematics?

Compare with this the extent of knowledge expected in other subjects. French and German, for example, together form one subject: to succeed, the candidate must be proficient in dictation in each language; translation from unseen authors; the grammar, history, and etymology of the languages; translation from English into French and German, besides translation from books appointed. For the first examination, books which might be chosen were—in French, Pascal's "Provincial Letters;" in German, Goethe's "Faust" *and* "Italiänische Reise."

The relative value attached to different branches of science is also worthy of remark. Chemistry, for example, is supposed to be so far inferior to Botany as an educational study, that the slight subject of *Heat* is added as a make-weight.

It is really hard to determine whether the compilers of these Regulations (the head-masters of one or two of our most important schools being amongst them, if report errs not) have acted simply in ignorance of what physical science in a school ought to be, or whether this is an ingenious device to strangle science as a school study, and to get rid of the obnoxious interloper by driving the weak and idle to it, and thus giving it a bad name as "the refuge of fools."

N. MARSHALL WATTS

PROF. MAX MÜLLER

It was decided at a Convocation held at Oxford on Tuesday that an inducement should be offered to Prof. Max Müller to continue to honour Oxford by remaining connected with that University. It would certainly have been a disgrace had no effort been made to retain the services of so eminent a scholar, which other countries are eagerly anxious to obtain. The proposal made by the Dean of Christ Church, which was carried by a large majority, was to relieve Prof. Müller of the obligation to lecture, and to provide for the appointment of a deputy, who should receive one-half of the salary of the present Professor. This scheme is confessedly somewhat of a makeshift; time was of importance, and the proper course, by statute, because lengthy, was not available. Vienna had offered the Professor a Chair of Sanskrit and provision for the publication of his books; and to this offer an immediate answer was necessary. The present, the Dean wished it to be understood, was a provisional arrangement in view of impending changes. The Dean was authorised to state that the Government "Universities" Bill would constitute an Executive Commission, with powers to receive schemes from Colleges, and to base upon them the new University and Collegiate organisation. He pledged himself there should be an opportunity given for considering in constitutional form the permanent arrangement of the matter at present in hand. He defended the decree from the charge of robbing Comparative Philology, for Sanskrit studies were an essential part of it, and the arrangement would give an admirable opportunity for some young man to make out his claim to the Professorship. He could have wished the arrangement had been more liberal, but, in fact, the University had come to the end of its tether. The Dean then dwelt on the high value of the Professor's services. He told how Mr. Max Müller had "audaciously" projected, when but a youth and a pupil of Burnouf, an edition of the Rigveda. For this he was forced to come to England, for which purpose he raised funds by translations, &c. Bunsen, on whom he called without introduction, had forwarded him to Prof. Wilson, and the India House, with sagacious liberality, took him up. Dean Gaisford had bidden men read Homer, with some ancient commentator, as the key to Greek literature. If these had been only accessible in manuscript, involving the reading, indexing, and perpetual annotation of infinite other MSS., who would have undertaken the task? And this was what Max Müller had done. Dean Liddell knew not whether to admire and wonder at most—his ardour in commencing, his perseverance in continuing, or his genius in the execution of his work. With regard to a recent statement as to Prof. Müller's future work, the Dean stated the fact to be that the University had accepted the offer of publishing a choice selection of translations from Sacred Books—at the utmost, twenty-four volumes. But this, it was obvious, was sufficient to prevent the Professor from enjoying the position of a sinecurist. The Dean concluded by enumerating a list of the Professor's distinctions, and urged the University to keep him if it could, how it could, while it could.

We must say that most of those who spoke in the discussion which followed missed the real point at issue. Prof. Max Müller has already rendered such important services to Oxford, to England, and to Science, and proved himself so competent to continue these services, that there should have been no hesitation whatever about endowing him sufficiently to enable him to continue his valuable researches unhampered. But we must be thankful for small mercies at present, hoping from the hint dropped by the Dean that better things are in store.

PROF. NORDENSKJÖLD ON THE JENISEI[1]

I HAVE before mentioned the great abundance of extraordinarily delicate varieties of fish which Jenisei yields, and that during our river journey we made as complete a collection of them as possible. The steamer's tedious voyage was, besides, employed by me in collecting statements regarding the names of the most important varieties, the price paid for them on the steamer, and their size.

	Common weight.	Greatest weight.	Price.
Njelma[2]	13 lb.	50 lb.	80 kop. per pood.
Tschir	6 „	25 „	10 „ each.
Omul	1½ „	3 „	2 „ „
Muksum	4 „	12 „	9 „ „
Salmon	16 „	80 „	—
Sterlet	3 „	30 „	150 kop. per pood.
Sturgeon	16 „	280 „	150 kop. per pood.
Silj	—	—	40 „ „

The trade, however, is carried on here in this way, that the goods to be purchased are valued in coin, but payment is made in goods at the merchant's valuation, on which account the true price is perhaps considerably below that which is here stated.

After the numerous crew on the *Alexander* and the "lodjors" had attended with great devoutness a festival service in the church of the monastery and a neighbouring chapel where the holy founder's dust and work-harness are preserved, after we had seen several of the remarkable things belonging to the monastery, and among them an exceedingly well-preserved Sclavonic Bible from the sixteenth century, and after I had paid a visit, along with the captain, to an aged cripple who in his youth had made a pilgrimage to Jerusalem, we steamed on. Our progress, as was commonly the case, was slow, in consequence of the strong current and the frequent stoppages, which of course we turned to account by making excursions to examine the natural history of the region, by conversing with the inhabitants, &c. The latter consist partly of Russians who have settled there, partly of natives, "Asiatics," who frequent the rivers during summer, partly on their own account, partly as employed by Russians. In such circumstances their dwellings consist of tents of quite the same form as the Lapp "kota." The Samoyede tent is commonly covered with reindeer skins, the Ostiak tent with birch bark. A number of dogs are always found in the neighbourhood of the tent, which during winter are used for general draught purposes, and in summer for towing up boats against the current—a means of transport on water which greatly surprised our seal-fishers. For this purpose a sufficient number of dogs are harnessed to a long line, one end of which is fastened to the stem of the boat. The dogs then go forward upon the level bank, where in this way

[1] Continued from p. 277.

[2] Njelma, Tschir, Omul, and Muksum are varieties of the Gwyniad. Silj is the fry, or young, of the same fish.

true dog-tracks are formed, and the boat, which requires only a moderate depth of water, is kept afloat at a sufficient distance from the bank by the rudder, which is managed by a person sitting in the stern of the boat. The boats are often hollowed out of a single tree stem, and may be notwithstanding, thanks to the dimensions the trees attain in these regions, of very beautiful form and very large. The dogs have a strong resemblance to the Eskimo dogs in Greenland, which are also employed as draught animals, which may perhaps be considered a proof that the same climatic circumstances and a similar method of employing a species of animals create like races. Most of the natives who come into intimate contact with the Russians at the present time, we are informed, profess Christianity. That many heathen customs still, however, cleave to them is shown by the following incident. At a "simovie" where we landed for some hours on Sept. 16, we as usual came upon a burying-place in the wood near the dwelling-houses. The corpses were laid in large coffins above ground, with a cross in nearly every case raised over them. At one of the graves there was a consecrated picture fixed to the cross, which must be considered an additional proof that a Christian reposed in the coffin. Notwithstanding this, several garments, which had belonged to the deceased, were found hanging on a bush near the grave, together with a bundle containing food, principally dried fish. At the graves of the richer natives we are informed that the survivors place, together with food, some rouble notes, in order that the departed may not be altogether destitute of ready money on his entrance into the other world. But that fine clothes are not considered any special recommendation with St. Peter was evidenced by the exceedingly shabby, tattered, and patched condition of the garments hung up at the grave in question.

Hitherto we had during our journey from Dudino up the Jenisei for the most part very fine, often warm, autumn weather. The first frost occurred south of Saostrovskoi on the night before Sept. 20, and from that date the temperature of the nights was generally under the freezing point. The days, however, continued to be warm and fine. The fall of rain was slight.

On the 20th we anchored at the mouth of one of the largest tributaries which fall into Jenisei from the east, viz., Podkammennaja Tunguska. Immediately below a welcome opportunity offered of taking soundings right across the river, which is here over a kilometre broad. A little distance from the western bank the lead showed four fathoms, afterwards the depth again diminished to 2½ fathoms, but afterwards increased anew to seven fathoms. At a number of other places also soundings were taken, which are believed to confirm the statement of the pilots that the depth of the river as far up as Jeniseisk is sufficient even for large vessels. However, in order to establish this with complete certainty, and to discover the most convenient channel for navigation, much more complete hydrographical surveys are required than those which we had an opportunity of making in passing.

As I have already mentioned, productive potato land and cabbage plots are to be found at the Skeptists' Colony, north of the Arctic circle, and the farther south we came, the more such patches of cultivation increased in size. No proper cultivation of grain is met with until we reach Sykobatka, situated in lat. 60°, but in the future it is quite certain that *when the woods and morasses are diminished*, a profitable agriculture may be carried on much farther north. Already from this point to the southern boundary of Siberia, or more correctly to the *steppe* lands of Central Asia, we have at most places more than 100 Swedish miles (1,000 kilometres), and if we consider that a belt of land of this breadth, for the most part covered with excellent, easily cultivated soil, extends right across the whole of Asia from Ural to the Pacific Ocean, we may form an idea of the immeasurable field of conquest for the plough of the cultivator which these regions offer, and the future which some time must open up for it.

Immediately south of Sykobatka we passed the church village Nasimowskoi, and a deserted gold-washer's "residence" lying right opposite, named after the first conqueror of Siberia, Jermakova. The "residence" originated in the discovery of beds of sand rich in gold in the pretty extensive territory of a tributary of Jenisei on the east of that river, which before the Californian discovery was renowned as the richest gold district of the globe. In a short time many colossal fortunes were made here, and the stories of the hundreds of *pouds* which one or another yearly washed, and the reckless, riotous mode of life of those whom fortune allowed to win the great prizes in the gold-washing lottery, still forms a favourite subject of conversation in the region. Heightened rates of labour and diminished supplies of the noble metal have, however, of late, led to the abandonment of a number of the washings which formerly were most profitable, and the others scarce pay for the working. Many of the gold washers who were formerly rich, have, in the attempt to increase their wealth, been ruined, and disappeared; and others who succeeded in retaining their *poud* of gold—that is the mint-unit that the gold washers prefer to employ in conversation—have removed to Paris, Petersburg, Moscow, Omsk, Krasnöjarsk, &c. All the "residences" are therefore now deserted, and form on the eastern bank of the river a row of half-decayed wooden ruins surrounded by young trees, after the disappearance of which in a short time only the tradition of the former era of prosperity will be found remaining. In one respect, however, these gold-washers have exercised a lasting influence on the future of the country; for it was through them that the first pioneers were spread in this desolate land, the first seed sown of the cultivation of the region.

At many places along the river there is to be seen besides another peculiar memorial chiefly from the time when thousands of labourers were collected at the gold-washings, viz., colossal flat-bottomed boxes formed of logs, which are here called "barks," which lie drawn up on the banks, more or less decayed. They were used for the transport of the necessaries of life on the river from Southern Siberia, and an idea may be formed of the calm flow of the Siberian rivers and their suitableness for water communication, from the fact that in this way goods were transported as far as the most northerly "simovies" on the Jenisei, on the main river, from regions situated south of Minusinsk, near the Chinese frontier and along its tributary the Angara from Lake Baikal; in fact, still farther, for even the river Selenga, which falls into Lake Baikal from the south, is navigable for a good part of its course. In order, however, to sail up these rivers from Jeniseisk there are required, as I have stated before, some operations for clearing the channel, but they are inconsiderable in comparison with the importance of the object. "Barks" of average size, built for the carriage of grain from Minusinsk, cost 300 roubles, load up to 130 tons, and are managed during the voyage down the river by fifteen men. After reaching their destination they are sold, in case a buyer can be found, for a few roubles. Notwithstanding their awkward shape they are well adapted for the river communication in question, and they would be still more so if during the down voyage of a considerable train formed of twenty or thirty of such craft, a small steam-tug could be had like those that are employed in the Archipelago of Stockholm. In this way the crew on each "bark" might be reduced to one-third; and the freight, which is already low, be farther reduced.

Since Sept. 20 night frosts had often occurred, which naturally considerably diminished the results of our excursions at the steamer's stopping places. We became therefore more impatient to reach our nearest destination. The strong current and the frequent stoppages delayed our journey, so that it was not until Sept. 30 that we could anchor at the town Jeniseisk. Here we stayed some days for the purpose of getting news from Europe, examining the fine collections made in several branches of natural history by Herr M. Marks, an exile, and settling our affairs; in connection with which I ought specially to mention that the owner of the *Alexander*, Herr Balangin, declined to receive any payment for our long voyage in the steamer, on which I made over instead, as a memorial to him and the excellent master of the steamer, Herr Jarmenieff, the Nordland boat, in which we began our river journey, and which had afterwards been brought hither in tow.

We then proceeded on our return journey by land through Krosnojarsk, Tomsk, Omsk, Tjumen, Ekaterineburg, Tagilsk, Perm, Kasan, Nischni-Novgorod, Moscow, Petersburg, and Helsinfors to Abo, and thence by steamer to Stockholm.

With the exception of some short stoppages in the large towns we travelled day and night, and a sketch of this latter part of our journey would therefore be occupied principally with the agreeable and friendly reception which we uniformly met with, and the interest which was universally felt in our polar journey. The correspondence which has appeared on this subject in the newspapers may perhaps free me from the obligation of saying more on this subject.

Before I finish this letter I ought finally to mention that the large collections in natural history made by the expedition both in Novaya Zemlya and the Kara Sea, and during our river journey on Jenisei, all, with the exception of a large collection of fish from Siberia sent by caravan, have come to hand in good

condition. For the examination and description of these collections I wish to employ the younger scientific men of eminence in our country, and as the most of them cannot without too great a sacrifice undertake year-long labours more or less foreign to their proper employment, I have made an application to the Government for a grant of 10,000 crowns (about 550*l.*) to defray the expense of working up the collections. If this application be granted, and the collections of the expedition of 1875 thus become not a dead museum-material, but fructify for the purposes of science, I hope that the sea visited by the expedition, formerly almost unknown, will soon be reckoned among those of our globe which are well known in respect of their natural history.

Part of these scientific researches besides concern purely practical questions, and I shall therefore, as they are concluded, give you a short account of them.

A. E. NORDENSKJÖLD

ON THE SPECTRUM OF NITROGEN AND THAT OF ALKALINE METALS IN GEISSLER TUBES, BY M. SALET

IN 1872 Mr. Schuster published the important statement that "nitrogen, heated in a Geissler tube with metallic sodium, ceased to give the characteristic channelled spectrum." He described the bright lines he got in this case, and attributed them to pure nitrogen, considering the band spectrum to be that of an oxide of nitrogen, a compound destroyed by the alkaline metal. These conclusions were afterwards disputed, for, in repetition of the experiments, the channelled spectra were seen to disappear after action of the sodium, but they were replaced by various spectra, none of which belonged to nitrogen; so that, after its purification, this gas could not be detected by prismatic analysis. The chemical compound really formed by the action of oxygen on nitrogen is (as M. Salet pointed out) peroxide of nitrogen, a very stable substance, whose spectrum does not coincide with that, the appearance of which is to be explained.

In a recent note to the French Academy, M. Salet affirms (1) that the channelled spectrum may be produced with nitrogen heated in contact with sodium; (2) that the disappearance of the nitrogen spectrum is due to that of the nitrogen itself, which is entirely absorbed by the sodium under the influence of the electric discharge; (3) that the spectrum described by Mr. Schuster may probably be attributed to vapours of the alkaline metal.

He describes some of his more decisive experiments. A closed tube of hard glass was procured, 12 cm. long and 2 cm. in diameter; at one end were introduced two aluminium electrodes, about 1 cm. apart; to the other end was soldered a tubulure with an enlarged part, into which was put a small piece of sodium, then the tubulure soldered to the mercury pump. A vacuum having been made, the sodium was heated; it swelled and boiled, parting with hydrogen; the swelling at length ceased, and at a higher temperature the sodium was slowly volatilised. Then the apparatus was separated from the pump, with the blowpipe; and the bright liquid and globule of sodium was brought into the tube. After cooling, the enlarged part was separated, and the tube directly fused on to the pump. Then exhaustion was recommenced, and the sodium volatilised, care being taken that the condensation of the metallic vapour occurred only in the half of the tube not holding the electrodes; and nitrogen, pure and dry, was then admitted. A vacuum was produced anew three times with the nitrogen, the alkaline metal being volatilised each time. Lastly, the apparatus was closed, having a pressure of about 5 mm. It was now possible to fuse the globules, unite them, and volatilise them afresh a dozen times in contact with the same mass of gas, without the appearance of the spark between the electrodes being in the least degree modified. The Holtz machine was used, or an induction coil with a Leyden jar; the interpolar space was roseate violet, and gave the channelled spectrum with the greatest distinctness. When the disruptive spark of the Holtz machine is employed, the jet of roseate violet light giving the channelled spectrum is instantaneous, as can be shown by a simple method (which M. Salet described). By volatilisation the sodium may easily be brought to the neighbourhood of the electrode. It there appears in the form of brilliant globules of a very pure silver white; but if the tube be set in action, the portions subjected to the action of the luminous discharge are at once tarnished. The metallic surface quite disappears, and is replaced by a brownish black. At the same time one sees in the appearance of the electric jet changes produced which are caused by a greater rarefaction. If the surface of the sodium be renewed the action continues, and the spectrum of nitrogen presently quite disappears; the light is yellowish, and due, for the most part, to sodium; there are, in general, slight impurities (from the electrodes and glass), which give some strange lines.

M. Salet made a direct experiment to show this absorption of nitrogen by sodium under the influence of electricity. He made a tube like the one that has been described, but bearing a truncated barometer; and introduced nitrogen at a pressure of 27 mm. The absorption of the gas was sufficient for one to be able to follow with the eye the ascent of the mercurial column. After a few minutes, having twice renewed the surface of the sodium, no difference could be perceived between the mercury surfaces in the two branches of the manometer.

The author also sought to characterise this absorption chemically. He broke a tube and treated separately with water a portion of the sodium remaining bright and a portion of the sodium altered by electricity. Into the solution he poured Nessler's test. One of the two liquids was strongly coloured yellow; it was that containing the altered sodium, the other was not altered in aspect. There was formed, then, under the influence of electricity, nitride of sodium decomposable by water with production of ammonia. This body is formed only at a temperature higher than red, like nitride of magnesium; or even is not produced directly at any degree of heat, like ammonia. M. Salet proposes to prepare and analyse it.

NOTES

WE hear with regret that the publications of the Geological Survey of the Territories by Prof. Hayden are likely to be stopped by the partisans of rigid economy in the U.S. House of Representatives. If this step be carried out it will be a serious loss to the scientific men of Europe, as well as of America. The discoveries which have been made by the staff under Prof. Hayden's direction are of the highest value, both from a scientific and a commercial point of view, and the liberality with which they have been circulated in Europe by the American Government has earned the gratitude of all who care for the advancement of knowledge. We trust that the rumour is untrue. If it be true, we hope that a voice of remonstrance will go forth from Europe. The possibility of a political change putting an end to a great national work like that of Prof. Hayden illustrates one of the worst flaws in the American Constitution, the cancelling of all Government appointments at the election of a new president.

M. LEVERRIER was not present at the Anniversary Meeting of the Astronomical Society to receive the medal which for a second time has been awarded him for his valuable Planetary Tables. Ill-health, caused by his recent great labours, was, we believe, the cause of his absence.

THE Annual Address of the President of the Geological Society will be given at the Anniversary Meeting to-morrow.

WE are gratified by the statement contained in the Queen's Speech, that the Government intend to introduce, in the course of the session, measures relating to Primary Education and the Universities. An important article on the subject appeared in Monday's *Daily News*, in which the defects of the present constitution of our Universities are forcibly pointed out. It is also shown how important a bearing the composition of the Commission would have in the character of its work, and that it would be but a proper act of deference to the valuable labours of the Science Commission if the new commissioners numbered some eminent representatives of science. What the direction of the proposed University reforms is likely to be may be to some extent gathered from the "inspired" hint dropped by the Dean of Christ Church, on Tuesday, in connection with the proposal to retain the services of Prof. Max Müller for Oxford. The Dean was authorised to state that

the Government "Universities" Bill would constitute an Executive Commission with powers to receive schemes from Colleges, and base upon them the new University and Collegiate organisation. We shall deal at length with this important subject at the proper time.

WE hear a rumour—which we think not unlikely to strengthen into a more certain sound—that the scheme for removing the Oxford Botanic Garden from its present historical and picturesque site to the bleak and arid "parks," has fallen through, and that immediate steps are to be taken to put the existing establishment on an efficient footing.

THE *Times'* correspondent, telegraphing from Rome on Tuesday, states that the Working Committee appointed by the Italian Government to act in concert with the General Committee in London for carrying into effect the exhibition of a loan collection of scientific instruments, to be opened at South Kensington in April next, have just addressed a circular to the various scientific institutions and individual *savans* throughout the country. It informs them that His Majesty's Government ardently desires that Italy should also take part in the Exhibition, and requests them to examine what instruments in their collections may be most worthy of being exhibited. It especially calls their attention to instruments of an historic character, and to those which have been constructed and principally applied in Italy. In the case of important instruments, of which the use cannot be dispensed with for the length of time the Exhibition may remain open, or which are of too fragile or too delicate a description to incur the risk of transport, but which, from their novelty or perfection, merit being brought before the notice of scientific men through this Exhibition, the Committee request that models and photographs of not too small a size may be sent. These models and photographs are to be made at the expense of the institution or persons exhibiting, but in cases where they may not be able to support the expense, the Committee, in proportion to the importance of the instruments, will supply the means from a fund set apart for the purpose by the Minister of Public Instruction. The Committee suggest that especial regard should be had to the quality and interest of the objects sent, rather than to the quantity.

A SUPPOSED error in the determination of the date when Easter Sunday should fall in the present year has been made the subject of communications to various metropolitan and provincial journals. We shall enter more fully into this question next week; meanwhile it may be stated that the presumed error is an imaginary one, according to the strict methods for ascertaining the date of Easter Sunday, which is correctly fixed by our almanacs to the 16th of April.

A COMMITTEE has been formed at the Hague for the purpose of organising a movement to erect a statue in that city to Spinoza, the 200th anniversary of whose death occurs this month next year. Foreign committees have also been formed, and among the members of the English committee are Professors Bain, Huxley, Jowett, Max Müller, Tyndall, Principal Tulloch, Messrs. G. H. Lewes and Herbert Spencer. Committees have also been formed in Germany, Austria, Belgium, the United States, Finland, France, Italy, and Switzerland. We do not require to say anything in favour of this movement; now that the matter has been mooted it seems surprising that nothing of this kind has hitherto been done to honour the memory of one of the greatest, purest, and most cosmopolitan of philosophers. The movement only requires to be widely known to meet with adequate practical support; many who may differ seriously from Spinoza's philosophy will be glad of an opportunity to show their appreciation of a great, courageous, and disinterested thinker. The treasurer is Mr. A. W. Jacobson, the Hague, the president being Dr. M. F. A. G. Campbell, of the same place.

AS regards our note in a former number on the Obi Expedition, we find that Dr. Finsch, of Bremen, whom we spoke of as about to accompany it, will himself be the conductor of it, and will be assisted by Dr. Brehm and Count Waldburg-Zeil, also the well-known microscopist Oscar Schmidt, of Strasburg. The Expedition is organised and sent out by the Verein für Deutsche Nordpolarfahrt in Bremen, and will proceed overland *viâ* Semipalatinsk and the Altai. It is expected to return late in the autumn.

WE are much pleased to see that Mr. E. L. Layard is gazetted to the Consulship of New Caledonia. In spite of the enormous pressure of business upon him during the late transfer of government in the Fiji Islands, Mr. Layard has managed to do a considerable amount of scientific work there; he has sent home large collections of birds, as well as several valuable papers.

WE have received a copy of the Statement by the Committee appointed by the British Association for the Advancement of Science for the purpose of continuing the investigation on the desirability of establishing a "close time" for the preservation of indigenous animals. Of the indirect and direct causes which tend to reduce the numbers of the Wild Fowl, which the "Statement" mostly concerns, the control of the latter of these causes forms its substance. It is shown that the ineffectual working of the "Wild Birds' Protection Act" depends on the insufficiency of the penalties imposed, the market value of Wild Fowl being high. It is also shown that as those who employ their time in the pursuit of these birds are in the habit of taking out a gun licence and of refraining from exercising their calling in certain waters and over certain lands, therefore they fully realise the nature of restraint, and would be willing—the better class of them, at least—gladly to recognise the propriety of a well-considered and stringent measure, which by effectually protecting Wild Fowl during the breeding season would secure to them a greater abundance at other times of the year. Whilst considering the protection of small birds as of minor importance, the Committee are of opinion that some steps for the regulation of bird-catchers might well be taken.

AT a congregation of Cambridge University on Feb. 3 the following grace passed the senate:—"That a grant of 50*l.* be made from the Worts Travelling Scholars' Fund to William Bridge, B.A., of Trinity College, to enable him to visit Naples, for the purpose of using Dr. Dohrn's Zoological Station, and making researches in Natural History, on the understanding that specimens be sent by him to the University, accompanied by reports which may be hereafter published."

AT the Royal Geographical Society on Monday last, Sir Henry Rawlinson intimated that Lieut. Cameron had solved the difficulty with regard to his followers, by purchasing a vessel at Loando for 1,000*l.*, in which they sailed early in January for the East Coast of Africa. By last accounts the explorer was still at Loando, whence he was to sail by the next steamer for Madeira. At the same meeting the Diary of the late Mr. Margary, from Hankow to Ta-li-fu, was read.

THE Council of the Society of Arts have appointed Mr. H. Trueman Wood as Assistant Secretary, under Mr. P. Le Neve Foster, Secretary of the Society. Mr. Wood has been for the last three years the editor of the Society's journal.

THE Senatus of the University of St. Andrews have conferred the degree of LL.D. on Mr. James Stuart, M.A., Professor of Mechanism and Applied Mechanics in Cambridge University, and on Mr. James Croll, of H.M. Geological Survey.

WE hear that ten days after the attempted ascent of Mont Blanc, noticed in our last number, an American lady ascended not only to the Grand Mulets, but to the summit itself, when

the temperature was $-25°$. She reached the top on Jan. 31 at three o'clock in the afternoon, when the sun lighted up an immense panorama. The thermometer marked at the Grand Mulets $-13°$ and the Grand Plateau $-19°$. The lady had with her several guides, and slept at the Grand Mulets on the evening of Jan. 31, returning by La Vallée on Feb. 1. She was enthusiastically welcomed by the inhabitants of Chamounix.

ONE of the Exhibitions granted to Cambridge University by the Worshipful Company of Clothworkers to be awarded to Non-Collegiate Students for proficiency in Physical Science, has been gained by Alexander Scott, educated at the University of Edinburgh. It is of the annual value of 50*l.*, and is tenable for three years.

AN open scholarship in Natural Science, of the yearly value of 90*l.*, tenable for five years, will be competed for at Queen's College, Oxford, on April 25, and following days. Candidates should signify, as early as may be in March, to the Provost, their intention of standing.

THERE are 616 boys now on the school-list at University College School.

WE are glad to see that an influential movement is on foot to form a Bristol and Gloucestershire Archæological Society. Such a society will have a fertile field for varied work in Gloucestershire, and we have no doubt, from the names which are identified with the movement, that the Society, when formed, will produce valuable results. The inaugural meeting will be held some time during the Easter holidays.

IT is proposed to open a school for field and laboratory instruction in Geology early in July, under the auspices of the Cornell University, at Ithaca, New York. The methods of instruction will be essentially the same as heretofore successfully employed at Penikese, Cleveland, and Peoria in the study of zoology and botany. The first and last quarters of the session will be spent at Ithaca, in laboratory work in connection with frequent lectures. About one-half of the session (second and third quarters) will be devoted to field work, with headquarters in an encampment in a mountainous region chosen for its fitness in illustrating geological structure. Prof. Theo. B. Comstock will have charge of this school. Similar schools with local field work where required are being organised under the direction of the professors in charge of the departments of physics, chemistry, botany, zoology, and free-hand drawing in Cornell University.

THE following College Lectures in the Natural Sciences will be given at Cambridge during the Lent Term:—Gonville and Caius College: On Anatomy and Physiology, by Dr. Bradbury; On Non-Metallic Elements, by Mr. Apjohn.—Christ's College: On the Physiology of the Senses, by Mr. H. N. Martin.—St. John's College: On Elementary Chemistry, by Mr. Main; Instruction in Practical Chemistry will also be given; on Palæontology (the Annuloida and Annulosa), by Mr. Bonney; on Physical Geology, by Mr. Bonney; on Elementary Geology, by Mr. Bonney.—Trinity College: On Sound and Light, by Mr. Trotter; on Electricity and Magnetism (Elementary Course), by Mr. Trotter; Practical Physiology and Histology, by the Trinity Prælector in Physiology (Dr. Michael Foster).—Sidney Sussex College: On Botany (Vegetable Histology and Physiology), by Mr. Hicks.—Downing College: On Physiology (Papers and Catechetical Lectures, with special reference to the Natural Science Tripos and the Second M.B. Examination), by Dr. Bradbury. On Chemistry (Papers and Catechetical Lectures), by Mr. Lewis.

A LAUDABLE scheme is on foot to unite the local societies of Cumberland into an Association for the Advancement of Science and Literature, having for its objects the spread of culture, mutual assistance in the organising of lecture courses, &c., wholesome emulation among the constitutent societies in the production of original papers, a yearly union in some town of Cumberland for the reading of original papers and discussion of subjects affecting the scientific and literary welfare of the community, and the publication, at the expense of the Association, of those original papers brought before the various societies which may be considered worthy by the Council.

THE *Iowa Weather Review*, No. 3, gives a brief *résumé* of the weather during each of the six decades of October and November last. Among the more interesting points noted are the occurrence of the Indian summer from the 18th to 24th October; the entire absence of snow or rain from the greater part of the State during November, and a rapid fall of temperature with a N.W. wind on the afternoon of the 28th November, amounting to upwards of 40° in twelve hours. The meteorological year, ending with November, was 3°·8 colder than the average, and Dr. Hinrichs, judging from the sequences of the weather during the past thirty-five years, ventured to predict a mild winter in Iowa. It appears from an examination of cyclones traced over Iowa that electrical phenomena manifest themselves at a considerable distance from the centre of the cyclone, a point of some interest to meteorologists, and deserving of further examination. A table showing the rainfall at sixty-five stations in the state, and another table giving the various meteorological averages at Iowa City during the past four years, complete this very interesting number.

IOWA being the only state in the Union having a meteorological system of its own reporting to a central office and furnishing state reports to the press, it has been resolved to exhibit at the Philadelphia Exhibition specimen schedules, books, postal cards, manuscript weather maps, publications, and diagrams of the climate of the State, in order to show the working of the Iowa Volunteer Weather Stations. It being manifestly beyond the resources even of the munificently supported meteorological system of the United States to undertake the investigation of many important inquiries, other states will probably be induced to follow the example of Iowa when the system there pursued is fully brought under their notice at Philadelphia.

IN a report to the Secretary of the Board of Regents, the erection of a physical observatory at the Iowa State University has been recommended. The detailed drawings on which the estimate of the sum required is based, show that the different storeys of the buildings are to be appropriated to a magnetic observatory, optical observatory and laboratory, self-registering meteorological instruments, and the keeping of records of observation, and a meteorological observatory, while on the roof will be placed a wind-vane, an anemometer, rain and snow gauges, and radiation thermometers.

THE Science and Art Department has issued a Catalogue of Apparatus for instruction in Practical Plane and Descriptive Geometry, Machine Construction and Drawing, Building Construction, Theoretical Mechanics, Applied Mechanics, and Steam, to the purchase of which the aid of 50 per cent. is given.

ACCORDING to letters received from Ternate by Prof. Parlatore, dated September last, from Dr. Beccari, we learn from the *Gardener's Chronicle*, that that adventurous traveller had discovered on Mount Arfak, in New Guinea, a Balanophora and an Araucaria, besides species of Vaccinium, Rhododendron, Podocarpus, Umbelliferæ, and a Drimys. We have merely these names to tantalise us, but they suggest a very interesting flora. From the same source we glean the following:—A School of Horticulture has been established at Copenhagen. There will be a national horticultural exhibition at Rome from May 6 to 14, the first of the kind that has taken place in that city.

THE additions to the Zoological Society's Gardens during the past week include three Burrowing Owls (*Pholeoptyrx cunicu-*

laria) from South America, presented by Mr. A. Q. Lumb; two Golden Pheasants (*Thaumalea picta*) from China, received in exchange; a Tuft-headed Deer (*Lophotragus michianus*) from China, the first living specimen sent to this country, a Chinese Water Deer (*Hydropotes inermis*), five Darwin's Pucras Pheasants (*Pucrasia darwini*) from China, deposited; a Blue-cheeked Barbet (*Megalæma asiatica*) from India, purchased.

SCIENTIFIC SERIALS

The *American Journal of Science and Arts*, January.—This number commences with a paper of "Contributions to Meteorology," in which Prof. Loomis gives results derived from an examination of the United States weather maps and from other sources. Among the points observed are: that periods of unusual cold are generally accompanied by descent of air from the upper regions of the atmosphere, and they are almost quite independent of direction of the wind; that both in summer and winter the force of vapour in Philadelphia is greatest with the wind which brings the highest temperature, and conversely; that the rainfall there shows a diurnal maximum about 6 P.M. and a minimum about 3 A.M.; that in the northern hemisphere storms increase in frequency as we proceed northward as far as latitude 60°, and perhaps somewhat further; and that storms travel with less velocity over the Atlantic (19·6 miles an hour) than over the continents of America and Europe (26 miles an hour). The author compares storm-paths in America and Europe.—Mr. Rowland continues his "Studies on Magnetic Distribution," and one result he arrives at is, that hardening is most useful for short magnets; in very long bars it does not increase the total quantity of magnetism, but only changes the distribution. It would seem that almost the only use in hardening magnets at all is to concentrate the magnetism and reduce the weight.—This paper is followed by a useful summary and comparison of recent researches on Sound by Tyndall, Henry, and Duane.—Prof. Draper endeavours to determine the correction to be applied for effect of temperature on the power of solutions of quinine to rotate polarised light. The presence of sulphuric acid changes the rotation power of the alkaloid by 100°. Quinine used to be given in the form of sulphuric acid solution, and in the recently more popular form of pills or the like, its action is much less, and less certain; this difference being doubtless due to the change of molecular arrangement which is revealed in action of sulphate solutions of the alkaloid on light.—Mr. Allen has a note on extinct wolf and deer species from the lead regions of the Upper Mississippi.

Poggendorff's Annalen der Physik und Chemie. Ergänzung. Band vii. Stück 1.—In a paper in this number on the mechanism of magnetic induction, M. Chwolson deals with a phenomenon in production of the magnetic state by external magnetising force, with which theory has seemed to be in discordance. This is the fact, that K, the so-called magnetisation number (or the ratio of magnetic movement produced to the magnetising force), in the case of small increasing forces, increases at the beginning, reaches a maximum, and with further increase of the force, becomes continuously smaller. This initial increase of K seemed to contradict the theory of molecular magnets capable of being turned round. M. Chwolson's object is to show that it not only does not contradict it, but is directly deducible from it, and he arrives at this result from a closer study of the processes which, according to Weber's fundamental hypothesis, must occur in a magnetised body, and from a simple assumption as to the origin of molecule-repelling force.—There are three (largely mathematical) papers in this number relating to the mechanical theory of heat; we merely give the titles:—On temperature and odiabata, by M. von Oettingen; On the specific heat and true heat capacity of bodies, by M. Herrmann; and On the second principle of the mechanical theory of heat deduced from the first, by M. Sjilz.—M. Voigt contributes the first portion of a careful investigation of the constants of elasticity of rock salt; he here treats the case of bending.

Der Naturforscher, Dec. 1875.—In this number we may note some researches by M. Fleck, of Dresden, which appear to damp recent optimism in reference to salicylic acid as a means of disinfection. He finds that carbolic and salicylic acids may, under certain circumstances, even accelerate fermentation. Benzoic acid is more effective against fermentation, and cinnamic acid still better; but their small solubility in water is against their use. The antifermentative action of benzoic, carbolic, and salicylic acids is dependent on the quantity of nitrogenous yeast-food; with increase of this the value of their action diminishes. The acids are not specific yeast poisons. Some experiments by MM. Kolbe and Mayer have a similar bearing.—From observations made during the German North Polar Expedition, it is shown by Dr. Hann that the density of the sea-water increases both at the surface and at 900 feet depth, with the latitude, and is in the Polar seas considerably greater than in the Tropics. Hence Dr. Hann concludes that a temperature-compensation of the water of the ocean by unequal proportions of salt does not exist; the heavy Polar water must therefore have a tendency to flow towards the equator.—In an interesting paper on the rate of propagation of excitation in sensitive nerves, M. Bloch shows that the methods for measuring this, which depend on the will of the experimenter (making a signal), are unreliable. He describes an ingenious new method; and he finds the velocity in the spinal cord 194 metres per second, while in the nerves it is only 132 metres per second.—There is an abstract of recent researches by M. Exner, which go to prove, in opposition to M. Edlund, that the supposition of a special power of expansion by the galvanic current in a metallic wire is unwarranted.—We further note some instructive researches by M. Stefan on the comparative power of heat conduction of different gases.

SOCIETIES AND ACADEMIES

LONDON

Linnean Society, Feb. 3.—Dr. G. J. Allman, F.R.S., president, in the chair.—William Hillhouse, Prof. E. R. Lankester, Daniel Pigeon, and David Robertson were elected Fellows of the Society. The following were proposed as Foreign members: Dr. Nylander, Professor of Botany, Helsingfors, and J. V. Barboza du Bocage, Direc. Roy. Zool. Mus., Lisbon.—Mr. Algernon Peckover exhibited a case of insects from Madagascar, collected by Mr. Kingdon. Among these Mr. Butler pointed out and made remarks on the scarce and remarkable *Actias Idae* of Felder's "Reise der Novara," the new Hawk-Moth, *Diodosida* sp., allied to a Congo species, also *D. fumosa*, Wallace, the *Danais chrysippus*, L., and its mimic, *Diadema misippus*, L., likewise a Homopterous genus allied to *Coomoscarta*, of Stäl.—Mr. Henry Trimen read a note on *Bœa commersonii*, R.Br. He observed that the supposition of Commerson having obtained the type at Magellan Straits is founded on an error; Mr. Rob. Brown regarded it as belonging to the Seychelles. Mr. C. Walter has quite lately discovered specimens growing on coral cliffs in the Duke of York's Island, which, through the Baron von Müeller, of Melbourne, have been forwarded to this country for identification. The probability is that Commerson himself obtained his examples in 1768 from the same locality; its true habitat afterwards having been confounded from the name "Praslin," attached to the original specimen, being given to widely different places.—Mr. Bowdler Sharpe read a paper on the geographical distribution of the vultures (Vulturidæ). These he divides into two sub-families Vulturinæ, with six genera, and Sarcorhamphinæ, with four genera, the distinctive characters and geographical range of which were commented on. The author likewise sketched out the classification of the birds of prey, as proposed by him in recent publications.—A short paper on New British Lichens, by the Rev. W. A. Leighton, was taken as read; in this six new species are described and figured.—The Rev. J. M. Crombie made some observations on two communications laid by him before the Society, viz., (1) *Lichenes capenses*, being an enumeration of the lichens collected at the Cape of Good Hope, by the Rev. A. E. Eaton, during the Venus Transit Expedition in 1874. (2) *Lichenes Kergueleni*, being an enumeration of the lichens collected in Kerguelen Land by the Rev. A. E. Eaton during the Venus Transit Expedition in 1874-5.

Mathematical Society, Feb. 10.—Prof. H. J. S. Smith, F.R.S., president, in the chair.—Messrs. A. Cockshott and R. T. Wright were proposed for election. The Secretary communicated a paper by Prof. Wolstenholme: Loci connected with the rectangular hyperbola, being inverse, with respect to its centres and vertices. Mr. Cotterill spoke upon the subject, referring to authors who had also treated of the loci in question.—Mr. W. Spottiswoode, F.R.S., read a paper on determinants of alternate numbers. The paper was founded on some unpublished notes on determinants and other functions of these numbers, communicated to the author by Prof. Clifford.—Mr.

Glaisher gave a brief sketch of a note by Mr. T. Muir, on the transformation of Gauss' hypergeometric series into a continued fraction.—The Chairman then dwelt in some detail on the partition of geometrical curves, the principal theorem being that, if D is the deficiency, the maximum number of distinct parts of the curve is D + 1. Professors Cayley and Clifford and Mr. S. Roberts took part in the discussion upon the paper.—Mr. J. Hammond gave an account of his paper on the sums of the products of r different terms of a series.—Prof. Clifford made a few remarks on pendular motion, in continuation of his paper read at the preceding meeting of the Society.—The President read part of a one-paged note on the pan-imaginary theory, by the Comte Léopold Hugo.

Royal Astronomical Society.—The Annual General Meeting was held at the Society's Rooms, Burlington House, on the afternoon of Friday, Feb. 11, Prof. Adams, president, in the chair.—Amongst the lives of deceased Fellows given in the Annual Report were those of Mr. Carrington, Prof. Selwyn, Mr. Vignoles, and Sir Edward Ryan; and amongst the deceased Associates were Prof. Argelander, M. D'Arrest, and M. Mathieu. Mr. Carrington has left the Society a legacy of 2,000*l*. He for many years served as secretary, and during that period published two important works, the one upon sunspots, and the other known as the Red-hill Catalogue of Circumpolar Stars. Mr. Carrington was the first to show the existence of the great drifts in the solar photosphere and to determine accurately the position of the sun's axis and the rotation periods of the various heliographic latitudes. After reading the Report of the Society, the President delivered his address upon the presentation of the Gold Medal to M. Leverrier for his investigations with reference to the perturbations of the outer planets.—The Astronomer Royal referred to Prof. Adams' address as one of a most exhaustive character, such as could only have been delivered by the Professor. The meeting then proceeded to the ballot for Officers and Council for the ensuing year, and the following gentlemen were declared to be elected:—President—Dr. Huggins. Vice-Presidents—Prof. J. C. Adams, Sir G. B. Airy, Mr. De la Rue, and Mr. Lassell. Treasurer—Mr. Whitbread. Secretaries—Mr. Dunkin and Mr. Ranyard. Foreign Secretary—Lord Lindsay. Council—Capt. Abney, Mr. Brett, Prof. Cayley, Mr. Christie, Mr. Glaisher, Mr. Knobel, Mr. Knott, Capt. Noble, Rev. S. J. Perry, Prof. Pritchard, Earl of Rosse, and Capt. Tupman.

Anthropological Institute, Feb. 8.—Col. A. Lane Fox, president, in the chair.—The President read his anniversary address, in which the papers read before the Institute during the past year were classified as follows:—Descriptive ethnology, nine papers; archæology, seventeen papers; ethnology, one paper; biology, three papers; comparative anatomy, four papers; psychology, one paper; sociology, two papers; philology, two papers. The remainder of the address was devoted to matters relating to the policy and internal affairs of the Institute. The Rev. W. Wyatt Gill read two papers on some traditions of the Harvey Islands, and demonstrated, by the assistance of genealogical tables of kings and priests, that the islands had not been inhabited more than about six centuries, and gave some instances from his own knowledge of canoes having drifted from very distant islands as a cause for the spread of the Polynesian race throughout the Pacific.—A paper by Mr. W. W. Wood, on some megalithic monuments in the Island of Rotumah was also read.

Physical Society, Feb. 12.—Annual General Meeting.—Prof. Gladstone, F.R.S., president, in the chair.—The following candidates were elected members of the Society:—Mr. W. R. Hodgkinson and Mr. H. M. Hastings.—The President read the report of the Council, of which the following is an abstract:—The Council points with satisfaction to the activity with which the work of the Society has been carried on during the year, as is shown by the number of papers read; and special reference is made to lectures which were delivered by M. Cornu, of Paris, and Mr. J. Norman Lockyer. The election of many distinguished physicists during the past year has given the Council much satisfaction, as it affords undoubted evidence of the progress of the Society and of the position it has now attained. The Society has to regret the loss of two members, Mr. Becker, who died on the 3rd of April, 1875, from bronchitis, in the fifty-fourth year of his age, and Mr. Waugh, who died on the 12th of October, from epilepsy, in his fortieth year. The Society has already published a work by Prof. Everett, on the Centimetre-Gramme-Second System of Units, and the Council is now in communication with the family of the late Sir Charles Wheatstone with a view to the publication of his papers. Attention is drawn to the benefit which the Society derives from the use of the lecture-room, &c., which were generously placed at its service by the Lords of the Committee of Council on Education. It has been considered desirable to arrange that the Council may grant admission to all meetings of a session to approved persons who are not members of the Society. In concluding the Council records its thanks for the services which Dr. Guthrie has rendered in his office of Demonstrator, an office which was formerly an important one in the Royal Society, and the Council believes that much might be gained if arrangements could be made for reproducing before this Society the experiments described in original papers which appear from time to time in this country and abroad. Several alterations in the Bye Laws were then discussed and adopted, and the following Officers and Council were elected for the ensuing year:—President, Prof. G. C. Foster, F.R.S. Vice-Presidents: Prof. W. G. Adams, F.R.S., and W. Spottiswoode, LL.D., F.R.S. Secretaries: A. W. Reinold, M.A., W. C. Roberts, F.R.S. Treasurer, Dr. E. Atkinson. Demonstrator, Dr. F. Guthrie, F.R.S. Other Members of Council: Latimer Clark, C.E., Prof. A. Dupré, F.R.S., W. Huggins, D.C.L., F.R.S., Prof. H. M'Leod, Dr. C. W. Siemens, D.C.L., F.R.S., Dr. H. Sprengel, Dr. W. H. Stone, Sir William Thomson, LL.D., F.R.S., Prof. W. C. Unwin, B.Sc., and E. O. W. Whitehouse. The proceedings then terminated with votes of thanks to the President, the Lords of the Committee of Council on Education, the Demonstrator, Secretaries, and Treasurer.

Geologists' Association, Feb. 4.—Mr. William Carruthers, F.R.S., president, in the chair.—On the drift of the North Wales border, by D. C. Davies, F.G.S.—The covering of drift is most complete on the eastern slopes of the border down to the plain of Cheshire and Salop. The greatest thickness is on a north and south line between Wrexham and Oswestry, the maximum of 150 feet being attained between Ruabon and Wrexham. The exceptions to this rule occur in certain hollows and valleys of the hilly region. The best exposures are at old Oswestry gravel-pit, 500 feet above level of sea, and the gravel ridge of Gresford. The author also gave a line of pit sections ranging from north to south. Five groups were described:—1. Deposits of the Pre-Glacial period, due principally to meteoric action upon adjacent rocks. 2. Stiff clay with boulders of local and northern origin, Lower Boulder clay. 3. Sands and gravels, with beds of mud and clay, Middle Glacial. 4. Stiff clay with boulders of local and northern origin, Upper Boulder clay. 5. Peat deposits, freshwater shell-beds, redistributed gravels, &c., Post-Glacial. The Upper Boulder clay (group 4) fills up inequalities in the preceding beds; it varies in thickness from 1 to 20 feet, in places thinning out altogether; the immense boulders which strew the surface come from this rather than from the Lower Boulder clay. Referring to these boulders generally, besides representatives of most of the Welsh rocks, and notably of the ashes, traps, and greenstones of Glyn Ceiriog, there are three principal varieties of "Scotch granite." The first deep red, with large crystals of red felspar; the second, pinkish, from an admixture of white quartz and red felspar, fine in the grain; the third is a greenish-grey rock, resembling specimens from Sutherland, Kirkcudbright, &c. A consideration of the phenomena presented by the three groups of the Glacial period leads the author to the following inferences:—1. The majority of the deposits are of local origin, being derived from the mountainous region of North Wales, then an archipelago of islands. 2. But, from the plentiful admixture of foreign matter, he infers a sea open to the north. 3. He insists upon the necessity of aqueous conditions: the coast would be partly ice-bound, but there was no general ice-cap. Besides the general alterations of level there were local alterations of level; proofs of this were to be seen in the neighbourhood of Oswestry, beyond which town the Scotch granites do not seem to pass. This the author considered due to currents deflecting the ice-rafts, &c. He concluded with an account of the redistribution of Glacial material in Post-Glacial time.—On the first Irish cave exploration, by G. S. Boulger, F.G.S. The author showed how the direction of the chambers of caves is influenced by joints, and drew attention to the distinction between caves and rock fissures as influencing their fauna. Unnecessary to assume that there was more carbonic acid in the air during the quaternary period, as water containing ·01 per cent. is the most efficient solvent of limestone, suggested that allowance might be made

for a fluvial period in considering the rate of deposition of stalagmite, and also for the influence of herbage in reducing the present amount of water percolating the rocks. The habits of beasts of prey and of aged animals frequenting caves was next considered. Shandon Cave, near Dungarven, was then described, and an account given of its excavation by Prof. Leith Adams and the author, during which remains of mammoth, reindeer, red-deer, wolf, fox, hare, goat, and various birds were found. The author concluded with some suggestions as to the state of Ireland and of its fauna during the period when these deposits took place.

Institution of Civil Engineers, Feb. 8.—Mr. Geo. Robt. Stephenson, president, in the chair.—The paper read was on Carlingford Lough and Greenore, by Mr. James Barton, M. Inst. C.E.

WATFORD

Natural History Society, Feb. 10.—Anniversary Meeting.—Mr. John Evans, F.R.S., president, in the chair.—The report of the Council and the Treasurer's account for 1875, showing that the Society was in a prosperous condition, were submitted to the members, and the President delivered an address on the work which had been done by the Society in the investigation of the natural history of Hertfordshire, and on the field of investigation open to the members.—Mr. John Evans, F.R.S., was elected president for the ensuing year.

VIENNA

Geological Society, Jan. 4.—The director, M. v. Hauer, read the anniversary report, describing the work of the Society in its various departments. During the last two years geological surveys have been continued in the Tyrol, in Galicia, and the Bukovina. In the Tyrol, Dr. Stache, with the assistance of M. Koch, and of two volunteers, M. Schranz and Dr. Posewitz, mapped the principal part of the Oetzthaler Mountains, and the Mountains of Tirol-Vorarlberg, forming the boundary of Switzerland, northward from the Ortler to the region of Balzers. At the same time M. Mojsisovics, with Dr. Hörnes and the volunteers, Dr. Reyer and Dr. Kotschy, completed the mapping of the region eastward from the porphyric massives near Botzen; northward to the Sexten and Puster valley; southward, including considerable parts of the Venetian Alps—as far as the line of dislocation near Primiero-Agordo-Zoldo ;] and in the east as far as the Piave; whilst M. Dölter made special investigations of the various eruptive rocks of the same region.—K. M. Paul, assisted by the Roumanian engineers, Const. Pilide and Const. Bottea, finished the detailed geological maps of the Bukovina, and in Galicia M. H. Wolf began the mapping on the eastern frontier of the country, between the Dniester southward, the line Siderow-Petlikowce northward, and the river Stry westward. On the whole 250 Austrian square miles have been mapped. Many other researches were carried on in almost all parts of the Empire. Among these are the following:—M. Stur examined the coal-mines of Bohemia, Moravia, and Silesia, for the purpose of making a detailed classification of their strata. By means of a grant that he obtained from the Urban-Schlönbach legacy, he was enabled to investigate and compare the large phyto-palæontological collections in Dresden, Halle, Berlin, and Breslau. Moreover, he visited chiefly on behalf of the museum of the Geological Society, some of the most important beds of Lias and Jura fossils in Salzburg and the Salz-Kamergut. The Ministry of Commerce, intending to establish a special school for workers in stone, commissioned the vice-director, M. F. Fötterle, to examine such rocks near Predazzo as might be used for technical purposes; this he did, and the school was opened on December 15, 1875. At the request of the same Ministry, M. H. Wolf made geological researches along the line of some railroads, and M. G. A. Koch along the recently planned Arlberg tunnel, &c. After a summary report of the labours performed by the committee for the geological investigation of Bohemia, and the Geological Society in Hungary, which had mapped 150 square miles of the south-western part of Hungary, in the last two years, M. v. Hauer proceeded to speak of the travels of members of the Geological Society and other Austrian geologists in foreign countries. He mentioned the labours of M. Stache in Tunis, of M. Tietze, lately returned from Persia, and of M. Lenz in the western part of Africa; from the last, a letter dated Lope in the Okando, July 28, 1875, arrived some days ago. To this place he had been conducted from Elimbareni by the old King Renoki, and he was going to pass through the dreaded regions of Oschebo (Mpangwe) in order to reach the Umbeke, and if possible the Mikaueke. "I shall try," Lenz writes, "to follow as far as possible a north-east direction; perhaps I shall succeed in reaching the upper course of the River Schari." Further, M. v. Hauer referred to Dr. Drasche, who intended to spend the winter on the Philippine Islands, and then to extend his investigations as far as Japan and Kamtschatka; also to the researches of Dr. Feistmantel in India. Finally, he gave a report of some expeditions sent from Vienna in the last two years to examine European Turkey and Greece. The work performed in the museum, the laboratory, and the study were not less successful than those in the field. In the museum have been newly arranged and classified according to their different zones, by M. D. Stur, the fossils of the Lias, Jura, and Tithon formations of the Northern Alps. This collection consists of 6,000 specimens under 1,214 numbers, found in 444 different localities; by M. Vacek have been arranged the neocomian fossils of the Northern Alps; by M. Hörnes, those of the tertiary from the Upper Danube and Vicenza. M. Stache completed the arrangement of the palæontological collections from Istria. In the course of the last two years the museum has received valuable presents in minerals, fossils, species of rock or worked stones from more than ninety institutions, offices, friends, and protectors of the Geological Society. The library has been augmented by 1,735 volumes and sheets. It contained, at the end of 1875, 20,971 volumes and sheets; 161 new folios were added to the collection of maps. In the laboratory there worked, besides the chief, M. v. Hauer, and the assistant, M. C. John, the volunteers Baron Jüptner, M. Schönfeld, and M. Mattesdorf. Many analyses were performed, especially of iron-stones, coals, cokes, &c., also of rocks. The collection of artificial crystals, a scientific treasure that no other museum or laboratory can show in nearly such abundance, has been again augmented materially, and comprises now more than 2,000 specimens. As to the publications of the Society, the *Verhandlungen* and the *Jahrbuch* appeared in regular course; from the Memoirs in quarto, five sheets, including fifty-nine single and sixteen double plates, were published. M. v. Hauer expresses his gratitude, in the name of the Geological Society, to the Minister, Dr. Stremayer, for the liberality and protection he always showed to it He also refers to the many kindnesses bestowed on the Society and its members in the course of the past year, and concludes by expressing his lively gratification at the resolution taken by Government to establish new professorships for geology in the Universities of Prague, Graz, and Innsbruck.—Papers were then read by Dr. Stache on the geology of the environs of Tunis; by Dr. R. Hörnes on the recently-discovered horizon with *Bellerophon peregrinus* at the base of the triassic beds in the Alps of South Tyrol; and by Dr. Dölter on some minerals of South Tyrol.

BERLIN

German Chemical Society, Jan. 24.—A. W. Hofmann, president, in the chair.—R. Fittig has found amongst the products of distillation of citric acid an anhydride $C_8H_{10}O_3$ (boiling-point 242°) of a bibasic acid $C_8H_{12}O_4$, a polymeride of crotonic acid, to which he gives the name xeronic acid. This acid yields well-defined salts, but passes at once into its anhydride when liberated. The same chemist is investigating the question if non-saturated compounds have free affinities. He is inclined to answer this question affirmatively for the following reasons. Hydrosorbic acid $C_6H_{10}O_2$ absorbs easily HBr, yielding $C_6H_{11}BrO_2$ monobromo-capronic acid; pyroterebinic acid $C_6H_{10}O_2$ does not. Sorbic acid $C_9H_8O_2$ forms $C_6H_{10}Br_2O_2$ dibromocapronic acid. Fumaric acid $C_4H_4O_4$ absorbs HBr yielding monobromo-succinic acid at 100°; malsic acid $C_4H_4O_4$ is simply transferred into fumaric acid at ordinary temperatures by the action of HBr.—E. Fisher explains the action of nitrous acid on diethylurea, and described the first hydrazine of the fatty series obtained as follows:—

$$\begin{array}{ccccc} C_2H_5\text{—}NH & & & & C_2H_5\text{—}N\text{—}NO \\ | & & & & | \\ CO & + \; HNO_2 & = & H_2O \; + & CO \\ | & & & & | \\ C_2H_5\text{—}NH & & & & C_2H_5\text{—}NH \\ \text{diethylurea} & \text{nitrous acid} & & & \text{nitroso-diethylurea.} \end{array}$$

The latter body diethyl-nitrox-urea, with iron and acetic acid

$$\text{yields—} \quad \begin{array}{c} C_2H_5N\text{—}NH_2HCl \\ | \\ CO \\ | \\ C_3H_4N\text{—}NH \end{array} \quad \text{which with HCl and water}$$

yields ethylamine-chlorhydrate, carbonic-anhydride and ethyl-

hydrazine combined with two HCl : $C_2H_5NH—NH_2.2HCl$.—R. Benedich has introduced into pyrogallol both one and two molecules of ethyl, obtaining pyrogallic ethers by heating pyrogallol with ethyl-sulphate of potassium and caustic potash in closed vessels.—P. Marquart proves that commercial nitric acid contains iodine, and thinks that the violet reaction of sulphuret of carbon observed by Dr. Friedburg may be owing to this element. The latter chemist contradicts this supposition.—O. Döbner has transformed diphenyl-sulphurous acid $(C_6H_4)_2SO_3H$ into a piphenol $(C_6H_4)_2(OH)_2$, a dicarbonic acid $(C_6H_4)_2(CO_2H)_2$, and a dichloride $(C_6H_4)_2Cl_2$. The latter by oxidation passes into dichlorobenzoic acid, thus proving that the two atoms of chlorine, &c., are contained in the same C_6H_4 group.—R. Meyer has transformed aniline-salts into aniline-black by treating them with permanganate of potassium.—P. Claessen recommends hydrate of baryta, prepared in a peculiar manner, for absorbing carbonic anhydride in quantitative analysis; separated by cotton-wool, some chloride of calcium is put into the tube to keep back the water discharged in the process. Numerous analyses prove its exactness.—T. Griess has treated nitrate of diazobenzol with ferrocyanide of potassium, transforming it thereby by reduction into a new substance, $C_{18}H_{14}N_2 = (C_6H_5N)_2C_6H_4$, and into azobenzol. This interesting discovery is most likely already known to English chemists.

STOCKHOLM

Academy of Sciences, Jan. 12.—The Academy approved a report by a Committee, consisting of Herr Edlund and Rubenson, appointed to consider a proposal by the Board of Woods for establishing meteorological stations for the purpose of scientific arboriculture.—Herr Nordenskjöld gave a sketch of the scientific results of last summer's expedition to the Jenesei.—Herr Edlund communicated a paper entitled "Some Remarks on Galvanic Expansion," in which he gave a theoretical explanation of the fact discovered by him some years ago, that a metal wire, through which a galvanic current passes, expands to a greater extent than corresponds to the heating caused by the current. He then exhibited a specimen of the newly-published Tables of Logarithms, which had been calculated and printed by the calculating machine invented by Dr. Wiberg.—Herr Andersson gave an account of the contents of a report by Herr J. E. Zetterstedt, of a journey he had undertaken last summer, with a grant from the Academy, for the purpose of examining the flora, and especially the mosses, of the Silurian formation of Wester Götland.—The following papers were given in for insertion in the Academy's publications:—Contributions to the actinology of the Atlantic Ocean, by Dr. G. Lindström; Examinations of the nucleus, and the parts nearest to it, of the Comet of 1874, by Dr. N. C. Dunér, of the University of Lund; On Arionids and Limacinids in the zoological department of Riks Museum, by the Intendent A. W. Malm; Remarks on the fossil flora of Bjuf, in Scania, by Dr. A. G. Nathorst. From the results of preliminary researches, the author concludes that the deposit must belong to the Rhætic formation, as it contains *Palissya Braunii*, Endl., *Tæniopteris tenuinervis*, Brauns., *Pterophyllum acuminatum*, &c. He gives short notes on most of the species found, of which some have not hitherto been described. The locality has only two or three species in common with the flora at Polsjö, formerly described by the author, and he thinks that the fossiliferous beds at Bjuf represent a lower level, and most closely resemble those of Seinstedt.—On the reciprocal lines of force, by Dr. C. F. E. Björling, of Lund University.

PARIS

Academy of Sciences, Feb. 7.—M. Peligot in the chair.—The following papers were read:—On the chemical action produced by means of the discharges of an induction apparatus, by M. Becquerel. The effects are more marked than with the ordinary machine. With only two or four chromic acid couples, M. Becquerel obtained the reduction of copper, nickel, cobalt, &c., from paper moistened with their solutions. He also forms amalgams, following Davy's method.—Note on the metallic reductions produced in capillary spaces, by M. Becquerel. In organic nature, electro-capillary effects doubtless occur on rupture of vessels, *e.g.* of a vessel traversing a muscle. Here the blood is diffused and a coagulum is formed, which is in contact, on the one hand, with the blood; on the other, with the liquid moistening the muscle; hence a reducing or oxidising action, and the products formed may concur in closing of the aperture. M. Becquerel also explains the chemical reactions in capillary spaces when a voltaic couple is added.—On the formation of ethers, by M. Berthelot. He here studies ethyloxalic, methyloxalic, acetic, and nitric ethers.—Report on a memoir of M. Peaucellier relating to the conditions of stability of arches.—Memoir on approximation of the functions of very large numbers, and on an extensive class of developments in series (first part), by M. Darboux.—New geometrical properties of the surface of the wave, which are interpreted by optics, by M. Mannheim.—On left curves of the fourth order, by M. Serret.—On the tunnelling operations in Mount Saint Gothard (continued), by M. Colladon. The compressing pumps employed give double the effect of those used in Cenis, and are only half the cost, while they occupy, with their motors, six or seven times less space. Four turbines at Goschenen and Airolo work twelve pumps, and the air obtained at pressure of eight atmospheres is 1,000 cubic metres per hour. The pumps give 200 strokes per minute, night and day. The boring machines used are those of Dubois and François, Feroux, MacKean, and Turrettini.—On the repartition of solar radiation at Montpellier during the year 1875, by M. Crova. The intensity of radiation is shown to reach maxima in spring and winter, and the coefficient of transmissibility in Herault, is found very considerable, exceeding sometimes 0·80 when the thickness already traversed is equal to 2.—On a new chloruretted propylene, by M. Reboul.—On difficulties connected with the preparation of pure aniline, by M. Rozenstiehl.—On the products of the action of chloride of lime on amines, by M. Tscherniak.—On granular conjunctivitis; *résumé* of two missions having for object the study of diseases of the eye in Algeria, by M. Gayal. The disease named is endemic in the region of the Tell and of Sahara. It is often developed through contagion with the secretion; and among local causes are the hot winds charged with sand, the solar reverberation, and the difference of temperature between day and night.—Crystallisation of meteoric waters, by M. Tissandier. In a drop of snow-water evaporated, a number of cross or dagger-shaped crystals are had; the form often taken by nitrate of ammonia in meteoric water. M. Tissandier tried in vain to reproduce such crystallisation artificially from dilute solutions of nitrate of ammonia; he always got crystals ramifying about a median line. He attributes the other form to presence of organic matters.—On the traces of dislocation presented by the tertiary formation in the valley of the Oise.

THURSDAY, FEBRUARY 24, 1876

REPORT OF THE VIVISECTION COMMISSION

NO one who examines this voluminous Report of the Commission appointed some months ago to inquire into "the practice of subjecting live animals to experiments for scientific purposes," can deny that the Commissioners have done their work thoroughly, as they have done it without delay. The Commissioners evidently entered upon their important inquiry with the determination of discovering the whole truth as to the practice of vivisection, and of eliciting the opinions and reasons not only of its advocates but of its most determined opponents. A mere glance at the long list of names of the witnesses will serve to assure anyone that the evidence which has been obtained is the expression of the most weighty and trustworthy opinion on both sides, and both the advocates and opponents of the practice must feel relieved that the Commission was appointed and has done its work: the former will be glad that the true condition of things is now before the public, that the worst, so to speak, is known, and the latter that they now know definitely what they have to contend against.

The bulk of the blue-book is of course occupied by the evidence. Prefixed to this is the Report and recommendations of the Commissioners, and in the Appendices are contained various documents which throw light upon the inquiry and enable the reader to learn exactly what has been done in the matter up to the present time, and what will be the starting-point of Parliament in discussing the Report. We need do little more here than lay the Commissioners' recommendations before our readers. In their Report they candidly discuss the varied methods and uses of experimenting on living animals, the bearings of the evidence elicited during the inquiry, as well as every possible suggestion as to what legislative action ought to be taken in reference to the matter. As might be expected from the character of the men who compose the Commission, every point of importance is brought prominently out, the subject is looked at all round, and from every point of view. Their recommendations, therefore, which they give after briefly referring to the two Bills of last session, will without doubt have great weight with all who take an interest in the matter. They are as follows:—

"What we should humbly recommend to Your Majesty would be the enactment of a law by which experiments upon living animals, whether for original research or for demonstration, should be placed under the control of the Secretary of State, who should have power to grant licences to persons, and, when satisfied of the propriety of doing so, to withdraw them. No other persons should be permitted to perform experiments. The holders of licences should be bound by conditions, and breach of the conditions should entail the liability to forfeiture of the licence; the object of the conditions should be to ensure that suffering should never be inflicted in any case in which it could be avoided, and should be reduced to a minimum where it could not be altogether avoided. This should be the general scope of the conditions; but their detailed application should be left to be modified from time to time by the minister responsible according to the dictates of experience. In the administration of the system generally, the responsible minister would of course be guided by the opinion of advisers of competent knowledge and experience. Dr. Playfair's bill provided a machinery for the purpose, and some arrangements of the kind proposed in that measure would be necessary. But we think it is inexpedient to divide the responsibility of the Secretary of State with that of any other persons by statutory enactment, and we recommend that his advisers should be from time to time selected and nominated by himself. Their names should be made known to the profession and the public. It may be found desirable that one of the conditions to be attached to a licence should be that the experiments should be performed in some particular place; but this is a detail which may vary with circumstances, and we think it ought not to be stereotyped by statute.

"The Secretary of State must have the most complete power of efficient inspection and of obtaining full returns and accurate records of all experiments made. Any place in which experiments are performed must be registered and open to efficient inspection. The appointment of an inspector or inspectors will be necessary, and we have seen that the analogy of the Anatomy Act has been appealed to by many high authorities. It is to be observed that the duties under that Act are of a nature much more mechanical than those which will be required in the present instance. The inspectors must be persons of such character and position as to command the confidence of the public no less than that of men of science.

"Abuse of the power conferred by the licence must, of course, render the holder liable to its withdrawal; but this will involve great disgrace; and the withdrawal of the licence of an eminent man without real cause might be a serious public mischief. We have felt it necessary, therefore, to consider what steps should be taken when the question of such withdrawal may arise. We think that the holder of a licence, when he shall receive notice that the Secretary of State intends to withdraw it during the period for which it has been granted, should be at liberty to demand a public inquiry; that this inquiry should be held before one of the Judges of the Supreme Court, with two competent assessors to be appointed by the Secretary of State, the Court having the full power of conducting it as a legal investigation by summoning and swearing witnesses, issuing commissions, and so forth:—that on the result of this inquiry, the Secretary of State should determine whether the licence ought to be withdrawn, and when he decides in the negative, should have the power of giving the holder of the licence the reasonable costs of his defence.

"Magistrates ought to be empowered, on cause shown, to authorise the police to enter and search the premises of persons suspected of performing experiments without a licence, and the performance of such experiments without a licence should be penal.

"It has been suggested that cases may occur in which an urgent necessity may have occasioned an experiment when there has been no licensed person within reach, and it has not been possible to apply for a licence; such as a sudden case of suspected poisoning, arising, perhaps, in a remote place, when the experiment has been reasonably considered indispensable, for the purpose either of cure or of medico-legal investigation. *Bonâ fide* cases of this kind ought evidently to be free from the risk of vexatious prosecution, and this can be secured by vesting in the Secretary of State the power of putting a veto on a prosecution.

"We believe that by such a measure as we have now proposed the progress of medical knowledge may be made compatible with the just requirements of humanity. In zeal for physiology, the country of Harvey, Hunter, Bell, and Darwin may well endure the test of comparison. We trust that Your Majesty's Government and the Parliament of this kingdom will recognise the claim of the lower animals to be treated with humane consideration—and will establish the right of the community to be

assured that this claim shall not be forgotten amid the triumphs of advancing science."

The recommendations, we are confident, will meet with the approval of all moderate persons on both sides. Indeed, some may be inclined to think that Science has made too great concessions to popular feeling; that she has made concessions all who take the trouble to read the Report and evidence will allow. The reasonable opponents of vivisection will no doubt also be prepared to make concessions, as they must admit that, after the evidence adduced in this inquiry, its uncompromising suppression would be a calamity to humanity; and they must also admit that the outcry of "cruelty to animals" has had a very slender justification. We hope the Report will speedily be brought before Parliament, and the recommendations essentially adopted, so that both for the credit of science and for the satisfaction of popular feeling the practice may be carried on under well-defined and universally understood regulations.

"THE GEOLOGICAL RECORD"

The Geological Record for 1874. An Account of Works on Geology, Mineralogy, and Palæontology, published during the year. Edited by William Whitaker B.A., F.G.S., of the Geological Survey of England. (London: Taylor and Francis, 1875.)

THE late Sir Charles Lyell used to relate how, on the occasion of a visit which he paid to M. Deslongchamps at Caen, the eminent French palæontologist rose from the piles of books amid which he was working, and exclaimed, with a sigh of relief, "Let us devoutly thank Heaven that our lot is not cast with the next generation of geological workers!—for how they will manage to grapple with the ever-increasing literature of the science I am at a loss to conceive." The difficulty which Deslongchamps thus playfully anticipated is now a present and pressing one, which, it is not too much to assert, is almost painfully felt by every scientific student and worker. While, on the one hand, it is absolutely impossible that any man can read everything that issues from the press relating even to his own department of science, yet, on the other, no one can afford to neglect the results which are being obtained by his contemporaries. It is sad to remember that a large part of the energy of the illustrious Dalton was wasted—owing to his not being able to make himself acquainted with what other chemists of his day were accomplishing—in solving problems which had been already completely disposed of. And we are persuaded that the painful questions of priority in discovery which frequently arise between the workers in the same branch of science ought to be referred, not to the existence of petty jealousies or of a disposition to take unworthy advantages, but to the difficulty which each investigator finds in consulting the latest published results of his fellow-workers in the same paths of inquiry.

So far as relates to the scientific memoirs of past years, the Royal Society has conferred an inestimable boon on the labourers in every department of science by the publication of its admirable "Catalogue," for the appearance of the first supplement to which we are now anxiously looking forward. Aided by a grant from the British Association, too, the "Zoological Record" gives a yearly summary of the work which is being accomplished in that department of science. It has long been felt as a serious and yearly increasing want—though one which has been already to some extent met by publications in France, Germany, and Switzerland—that no similar work of reference for the geological sciences has hitherto appeared in this country. We are now happy to inform the readers of NATURE that this want has been very admirably supplied by the volume, of which the title appears at the head of the present article.

In the preface to this work the editor gracefully notices the important services rendered by his fellow-workers, but he has not referred to the great difficulties which attended the first establishment of this important year-book of reference; for the overcoming of which difficulties we are mainly indebted to his own energy and perseverance. When the proposal for this work was first drawn up by Mr. Whitaker—whose well-known works on Tertiary Geology, and especially those relating to the vicinity of the metropolis, gave him such claims on the confidence of geologists—the Council of the British Association did not find itself in a position to accord to it immediately the same assistance as it annually gives to the "Zoological Record." Undeterred by this preliminary difficulty, however, Mr. Whitaker determined to proceed with his task unaided. A list of guarantors was formed, who agreed to indemnify the editor against pecuniary loss; and among those who thus signified their sense of the importance of the work, we find the names of Lyell, Poulett-Scrope, and Logan, who have not lived to witness its publication, together with those of almost all the leaders of geological science in this country. Happily, the sale of the work has sufficed, even during this its first year of publication, to cover all expenses; and a grant from the British Association will serve to remove any anxieties which the editor might have felt as to its future.

In the plan of the work we think that Mr. Whitaker has exercised a very wise discretion. He has not attempted anything like reviews or critical notices of the various books and memoirs which he catalogues. In the publications in which this has been done, like the "Die Fortschritte auf dem Gebiete der Geologie, 1872," edited by Dr. Hermann J. Klein, or the "Revue Géologique Suisse pour l'Année 1874" of Ernest Favre, we have nothing like the complete work of reference supplied by the publication of the "Geological Record." In the latter, the notices of the various contributions to geological science are confined to terse statements of the subjects treated in them, with an enumeration of the plates and maps by which they are illustrated. Where, however, a short account of recent discovery or a summary of a new classification could be given in a few lines, or the bearing of a memoir on the progress of science briefly indicated, this has been often well done in the work before us.

The difficult task of classifying the memoirs according to the various subjects of which they treat has been, on the whole, very successfully accomplished; and for the general superintendence of the work, Mr. Whitaker has secured the aid of a number of well-known cultivators of different departments of the science to act as sub-editors. Mr. Topley takes the departments of British and Economic Geology; Mr. Labour deals with the works relating to Europe, the Arctic Regions, and America; Mr. Drew with those on Asia; and Mr. Robert

Etheridge, jun., with those referring to Australasia. The important department of Physical Geology has been undertaken by Prof. Green, and those of Mineralogy and Petrology by Prof. Rudler; while the science of Palæontology has been equally well cared for—Mr. Miall taking the papers referring to the Vertebrata, Prof. Nicholson those relating to the Invertebrata, and Mr. Carruthers those on Fossil Plants. Besides the sub-editors, a number of other contributors have given their assistance in connection with this important work.

When we reflect on the immense body of literature on the different branches of the natural sciences which is yearly published, we shall find good reason to be satisfied with the approximately complete character already attained by this, the first volume of the "Geological Record." It is only necessary to refer to the yearly increasing activity of our great scientific societies, the continual formation of new local associations and field-clubs (whether connected with particular districts or with our Universities and public schools), most of which publish their own transactions, to show the difficulty of making a complete catalogue even of the scientific publications which appear yearly in the British Islands alone. But when we add to these the prolific publications of the different State surveys and the numerous scientific institutions of the United States and of our own colonies and dependencies; when we bear in mind the scientific activity exhibited by the French, German, and Italian speaking populations of Europe, and the books and journals written in languages, which of course few scientific men are able to read, such as the Russian, Danish, Dutch, Scandinavian, Hungarian, Bohemian, Serbian, &c.; and when we recollect that geological memoirs are published even in Japan and Tahiti!—we may have some idea of the magnitude and difficulty of the task with which the conductors of the "Geological Record" have to grapple.

In illustration of the energy which has been brought to bear upon this task, we may mention that the first volume of the "Geological Record" extends to nearly 400 pages; that the journals of which the contents, so far as they relate to geology, have been given in abstract, number nearly 200; and that the separate entries of books, memoirs, and maps exceed 2,000.

Henceforward, the yearly volumes of the "Geological Record" must find a place on the shelves of every scientific library; and in congratulating the editor on the manner in which he has surmounted the first and greatest difficulties of his arduous undertaking, we find only one cause for complaint. So far as the title-page shows, no arrangements have been made with agents residing abroad for the circulation of the work in America, the colonies, and on the Continent. We are persuaded, so very general is the use of the English language among the scientific men of all parts of the world, that so soon as this omission is remedied, the foreign circulation of the "Geological Record" will equal or even exceed that which it already has at home; while most valuable aid will be given in the preparation of the future volumes of the work by the secretaries of foreign societies and the editors of Continental and American journals sending copies of their publications, immediately that they appear, to the conductors of this important work of reference.

J. W. J.

OUR BOOK SHELF

Lessons on Rigid Dynamics. By the Rev. G. Pirie, M.A. (London: Macmillan and Co., 1875.)

THIS work treats of the geometry of motion, D'Alembert's principle, reduction of the expressions for the effective forces, moments and products of inertia, energy, precessional motion, and certain differential equations which occur in treating of the subject of Rigid Dynamics. There is an excellent selection of exercises, many of which are worked out, and the answers are in many cases accompanied by useful hints. The book appears to us to be in every respect an admirable one, and to be a good introduction to the study of this difficult branch of natural philosophy. We agree with Mr. Pirie in thinking that much of the difficulty students find in this subject arises from the explanations which are given in the ordinary text-books being for the most part brief and often, in consequence, obscure. We believe the author's hope that his book may be useful not only to students of natural philosophy, but also to engineers, is likely to be realised. We cordially recommend the book.

The Secret of the Circle, its Area Ascertained. By Alick Carrick. (London: H. Sotheran and Co. Chiswick Press, 1876.)

ONE more contribution to the long list of works on the Circle, put forth with the usual assurance that now the question must be set at rest. "Dedicated with great deference to the different schools of learning and to the intelligence of the public generally in this and other countries, in the confident hope and full belief that the truth pointed out in these pages will soon be acknowledged." There is a prefatory notice taking us down to page 16 (there are 48 pages in the pamphlet), from which we learn that the author's name is an assumed one, and that he is now dead. "Introductory" takes us to page 39. "The Secret of the Circle, its Area Ascertained," occupies the rest of the book. The Rule given is, "Diameter $\times$ radius $+$ four-sevenths" (*sic*), hence our friend π is equated to $\frac{22}{7}$. There are ten figures, some pretty to look at, but there is a dearth of letters, and it is often hard to make out what parts are intended in the demonstration. There is much that is true and not new; for instance, that the inscribed dodecagon is equal to the inscribed square and half that square; what is new is not proved to be true. Thus to get the result, the circular segment bounded by the side of the dodecagon ought to be for his purpose $\frac{1}{84}$ (radius)^2, and this is not shown on pp. 44, 45, for it is not proved there that Q contains the nine segments which it is said to contain. Hence we are led to say that the truth about the Circle is *not* to be found *here*.

Australian Heroes. By Charles H. Eden. (Society for Promoting Christian Knowledge).

MR. EDEN has written a very interesting book. As might be surmised from the title, he has brought into prominence the adventures of the explorers of Australia rather than the results of their explorations. Australia is unlike almost any other country which has been the field of exploration; its sameness, the dreary tameness of the bulk of the continent, the comparative paucity and low state of the aborigines, deprive an explorer's narrative of many of the points of interest to be met with in the case of other countries—Africa, for example, South America, or even the Arctic regions. Still this little book shows that during the comparatively brief period that Australia has been a field for exploration, there have been plenty of deeds of daring and determination and self-sacrifice in the cause of scientific knowledge, to render any skilfully

written narrative of Australian discovery interesting. Mr. Eden has told the story attractively, and the reader will not only be greatly interested, but will have a fair idea of what has been done to extend our knowledge of the "fifth continent" from its first discovery down to the trans-continental journeys of Warburton and Forrest—the latter, however, being referred to in a sentence or two.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Dr. Bastian and Prof. Tyndall on Spontaneous Generation

I BEG you to allow me a few lines to protest, as Prof. Tyndall has done elsewhere, against Dr. Bastian's proceeding, in citing a number of observers *in support* of his views (NATURE, vol. xiii. p. 284), whose researches taken in each case—as a whole—furnish conclusive arguments *against* his views.

It is only by an inadequate statement that the observations of Dr. Pode and myself—which appear in Dr. Bastian's list—can have this signification attached to them. Where we obtained the result which Dr. Bastian obtained, we were able to trace it to a vitiation of the experimental conditions. Our results conclusively and categorically contradicted the particular assertions contained in Dr. Bastian's book, the "Beginnings of Life," into the truth of which we set ourselves to inquire.

Radiometers and Radiometers

I HAVE recently been trying some experiments with a radiometer, obtained from Mr. Browning, and as some of my results are different from what I was led to anticipate, I should like to know whether there is anything special in my particular instrument, or whether other people have noticed the same things.

In Mr. Crookes' paper on "The Mechanical Action of Light," *Quarterly Journal of Science*, No. xlvii. p. 348, he states that "when only dark heat is allowed to fall on the arms [of the radiometer], as from a vessel of boiling water, *no rotation whatever is produced*." (The italics are mine)

Now I find that my radiometer is particularly sensitive to dark heat, the presence of a heated copper wire, or still more that of an iron poker when only slightly warmed, instantly accelerating the number of revolutions.

But more than this: when exposed in a room to diffused daylight, the velocity of rotation is greatly influenced by the temperature of the room, and is by no means an indicator of the amount of light only.

One morning this week during the frost, upon looking at my radiometer, it appeared to be motionless, although standing not far from my study window. When placed nearer to the light it revolved, but so slowly that I thought the instrument must have received an injury. The room at the time was very cold, as the fire had not been lighted. After the fire had been lighted and the temperature of the room raised, the velocity of rotation increased, and upon observing the instrument just before dark, when the room was very warm, the rotation was considerably greater than it had been in the window in the middle of the day, although at the time there was only just enough light in the room to enable me to see the instrument at all. When I brought the radiometer near to the fire, which consisted only of dull hardly glowing coals, the rotation of the arms became so rapid as to render them almost invisible.

Upon taking the instrument out of doors between five and six o'clock in the afternoon, the thermometer a few degrees below freezing-point, the arms revolved slowly from right to left as usual, but upon bringing it near to a mass of snow, and shading the light off by some pieces of wood, I could see that the arms revolved slowly in the opposite direction, that is, in the same direction as the hands of a watch. Later in the evening I held the instrument in the open air in bright moonlight, the thermometer being at 24° F., and the rotation was again in the same direction as the hands of a watch. The next morning, when the temperature was nearly the same, but the air foggy with only feeble light, the arms revolved at about the same rate but in the usual direction, from right to left. In the evening I again held the radiometer in the moonlight in the cold frosty air; the rotation was as before, from left to right. Carrying the instrument in my hand I approached the house, the hall door of which stood open. As I came within reach of the light and heat the rotation diminished, and at length ceased, but upon entering the hall it commenced again, only in the opposite direction. In fact, I could stand in such a position that upon moving a few feet either way, I reversed the direction of rotation, while between the two there was no motion at all.

I afterwards repeated the experiment in a different form. I placed the instrument in a cupboard in a very cold room, with a considerable quantity of ice. Upon just opening the cupboard door and peeping in, I could see that the arms were revolving very slowly, but distinctly, from left to right. Upon opening the door a little wider the motion ceased, and when still more light was admitted the motion was reversed. I then removed the ice and nearly closed the door—the rotation ceased entirely; but upon introducing a piece of heated iron the arms spun round as fast as they usually do in full sunlight, and this, be it remembered, when the cupboard was almost dark, the door being only just sufficiently open for me to see the instrument, certainly not more than a quarter of an inch. T. N. HUTCHINSON

Rugby, Feb. 12

Since writing the above, I have been favoured with a note from Mr. Crookes, in which he points out to me that his results have been obtained by means of radiometers constructed with *pith* discs, and having no metal at all in the moving parts. In the little instrument that I have used the discs are of mica, blackened, of course, on the alternate faces, but mounted upon four metallic arms, apparently aluminium foil. Mr. Crookes observes: "I long ago gave up metallic instruments owing to their erratic movements while radiating or absorbing heat. I have mentioned this peculiarity of metallic radiometers in my papers for the Royal Society."

As this difference between the instruments used accounted, to some extent, for my obtaining results so different from those described by Mr. Crookes in the paper referred to, I felt at first that there was no further need to trouble you with these remarks, and that they had better be consigned to the waste paper basket. Upon second thoughts, however, it seems to me that there is still something that requires explanation, or, at all events, that I do not understand, in the different action of dark heat on pith only, and on mica mounted on thin metallic arms. The four arms are very fine, equally bright, and similar in all respects, hence it is difficult to see how rotation should be produced by the action of heat on the metallic parts of the apparatus. The vacuum, no doubt, is not so perfect as that obtained by Mr. Crookes with his exquisite Sprengel pump, but even this would hardly account for the "erratic movements" that I have observed.

I may add that since performing my experiments I have learnt that one of my pupils in Rugby School, Mr. H. F. Newall, has observed very similar results with a radiometer in his possession. T. N. H.

The Sailing Flight of Birds

HAVING had during several long voyages in the Pacific considerable opportunities for observing closely the flight of sailing birds, and especially of *Diomedea Melanophrys*, or "Mutton Bird," as I believe it is called by the Australians, a few suggestions on the subject may perhaps not be uninteresting to your readers.

This bird differs considerably in size from the albatross of the Cape, but as the principles of its flight are the same, the few suggestions I wish to make will apply with equal force to both species, and indeed to all sailing birds.

The *Diomedea* of the Cape it is well known can support itself in the air for a very long time without flapping its wings, and in "The Reign of Law" it is stated that "sometimes for a whole hour together this splendid bird will sail or wheel round a ship in every possible variety of direction, without requiring a single stroke of its pinions." This *may* be accurately true, but in the case of the smaller albatross I refer to, between one and two minutes, or perhaps 1,000 or 2,000 yards in space, is more approximately the limit to which the bird's power of sailing is exercised. When the flight begins after rest the bird appears to feel very considerable difficulty in rising from the sea. It runs along the surface for some distance, flaps its wings very vigorously, and continues to do this after it has left the water, until it acquires a

satisfactory velocity. Its subsequent sailing flight until it again increases its rate of speed by flapping, I would suggest to be merely a utilisation of this original *vis viva* to the utmost possible advantage, the ascending and descending movements of the bird being nothing more than a change from actual to potential energy, and *vice versâ*. Suppose, for the sake of simplicity, that the wind is dead ahead, and that the bird commences sailing horizontally with a certain *vis viva*. With this, by fixing its wings so as to present inclined planes to the direction of the wind, it is able to rise to a certain height, the velocity decreasing in some ratio to the ascent, and if the highest point capable of being reached is attained, the bird for the instant comes to rest; up to this moment the actual energy has been gradually changing into potential, and the bird gaining thereby a position of advantage. It is, however, extremely rare that this position is attained—most frequently the horizontal velocity is only partially destroyed. The planes of the wings being now changed with reference to the direction of the wind, the bird begins to descend; the potential energy is transformed into actual, and velocity is acquired, to be again changed into potential, and so on until it becomes necessary to renew it. The line of flight, therefore, of an albatross going directly against the wind consists of a series of undulations, the summits of which correspond to the instants of least relative velocities, or positions of greatest potential advantage; whilst the lowest points correspond to the instants of greatest relative velocity and least potential advantage.

During all this time *vis viva* is of course being extracted by the resistance of the wind, and the velocity after a while is so diminished that the bird loses its power of rising to a satisfactory position of advantage. It is then that flapping recommences and new power of flight is acquired. When it is remembered that the weight of a Cape albatross varies from 16 lb. to 20 lb., and the stretch of wings from 10 to 12 feet, it will be evident how great is the potential energy of such a bird at the height say of 100 feet, and also how complete is its power of utilising that energy. The question may be asked, how long will it be before 2,000 foot-pounds of work have been extracted by air moving at the rate of sixty miles an hour? for until it has been extracted, or nearly so, the sailing flight of the albatross need not cease. By means of a suitable mechanism for changing the inclination of the wing planes every few seconds, the sailing of the albatross, I believe, might be simulated without great difficulty. It is generally supposed that the stronger the wind the greater is the power of sailing-flight. In the special instance referred to, viz., that of sailing directly in the teeth of the wind, this is not the case. A good breeze is evidently better than either a very strong wind or a calm. In the one case, a too great resistance destroys the *vis viva* too rapidly; in the other, the bird suffers from a want of sufficient resistance, very much as a kite does during a calm.

In sailing in any other direction a violent wind may more or less aid the flight, and the velocity attained in some instances be enormous and very deceptive. It is this element, viz., the velocity acquired by sailing obliquely with the wind, that is so difficult for the eye to eliminate in estimating the actual power of the bird to sail against the wind. In flying with the wind, the resistance to the stroke being greater, the necessary speed may be more rapidly acquired and with fewer strokes, provided the bird has the requisite strength. But, as might naturally be supposed, sailing directly with the wind for any considerable distance is rarely or never seen, the bird not finding sufficient resistance in the air for its support.

From what has been said it will appear that the superior sailing power of the albatross, in comparison with other birds, is due—

(1) To its ability to acquire readily very great *vis viva* by means of its extremely powerful wings.

(2) To its almost perfect power of utilising this *vis viva* for the purpose of ascending or descending, *i.e.* of changing from a position of greatest actual to greatest potential energy and *vice versâ*, with least loss of power through resistance of the air.

The above implies an extraordinary rigidity as well as absence of concavity of the wings, by which the bird is enabled to hold them in their place like two rigid planes, and thereby present their surface to the wind under the most favourable circumstances possible. The tremulous movement seen at the tips appears to be nothing more than vibrations due to the want of absolute rigidity in the pinions. The above suggestions, if tenable, furnish an explanation also of the flight of the flying fish—the undulatory motion, or rising over the crest of a wave, which has puzzled so many casual observers, being merely a change of some of the *vis viva* of its flight into potential energy. This means necessarily a loss of velocity depending on the amount of rise, and implies the power of the fish to change its wing planes so as to ascend or descend. The original *vis viva* has of course been created by a preliminary rush through the water before emerging.

It will be seen from what has been said that the principle suggested, rightly or wrongly, as fully explaining the flight of the albatross, is that of a body—gifted with the most perfect power of placing itself in a position of advantage—sliding up and down inclined planes under the most perfect conditions possible.

R. A.

The Use of the Words "Weight" and "Mass"

In the review of Dr. Guthrie's "Electricity and Magnetism" (NATURE, vol. xiii. p. 263) the following words occur in reference to Dr. Guthrie's definition of the absolute unit of electric resistance: "Here, irrespective of other considerations, there is the fundamental error of using the term *weight* instead of *mass*."

It is very unfortunate that the word "weight" is ambiguous; and that the ambiguity is actually so great as to lead to all but universal confusion of ideas. It is *not* really improper to use *weight* as synonymous with *mass*, and, had Dr. Guthrie meant to refer to *mass*, his using the term weight would not have constituted any fundamental error. He would only have been using an old ambiguous word in the more authoritatively established of its two common meanings. By an Act of Parliament (18th and 19th of Victoria, Chapter 72, July 30, 1855) for the special purpose of establishing standard weights and measures, it is enacted that a certain piece of platinum referred to as a "weight of platinum" shall be denominated the Imperial Standard Pound Avoirdupois, and shall be deemed to be the only standard of weight from which all other weights and other measures having reference to weight shall be derived, computed, and ascertained. The gravity of a mass, or of a piece of matter, is not once named, or in any way referred to, in the Act as a thing for which a standard is meant to be established by that Act, nor is the word *force* or the notion of force put forward in any way in the Act. Thus the meaning attributed in the Act to the word *weight* is the same as is distinctly expressed in scientific language by *mass*.

However, on turning to Dr. Guthrie's book itself, I found a striking example of the troublesome perplexity which is involved in the ambiguity of the language in common use. A few lines below the passage touched on by the reviewer, the following sentence and appended note occur. (Text), "From the work done by the current in the experimental wire, the resistance in that wire is found, and this resistance is considered unity when the above measures are units, namely, 1 second time, 1 meter space, and 1 gram weight or force." (Note appended), "The force actually taken as unity is $\frac{1}{9{\cdot}81}$ gram, for this force acting on 1 gram for 1 second will give it a velocity of 1 meter a second." The text and the note are utterly irreconcilable. The confusion is complete.

I do not say that no one can possibly understand the subject with the common nomenclature; but I do say, from considerable experience in Glasgow University, where we are in the habit of using the absolute or kinetic system of force-measurement in *all* our calculations with the students of the Natural Philosophy Class, that it is extremely difficult to explain, with the old nomenclature, the beautiful, and in itself simple, kinetic system of Gauss, together with its connection with the gravitation system of force-measurement.

This session, however, I have found a very great simplification in adopting a suggestion of Prof. James Thomson to do away with the word *weight* altogether in cases in which its employment would involve ambiguity. He would still readily use the name, a pound weight, for the standard piece of iron or brass used in weighing; and would continue, so long as our present non-decimal system is maintained, to use the commercial term, a hundredweight of iron, meaning a certain quantity or mass of iron. But he has proposed that when we mean *mass* we should avoid the word weight as far as possible and use the word mass, and that where we mean downward force due to gravitation, called by Dr. Guthrie and his reviewer, *weight*, we should use the word *gravity*. Thus we may speak of a one pound force, or we may say "the gravity of a pound," but never "the weight of a pound." We can scarcely get rid altogether of connecting the idea of heaviness with the word weight, nor would our dictionaries at present allow us to do so; but it is quite proper to feel that, in speaking of a certain weight as being too great to

be resisted by a certain chain, we are using a colloquial and inaccurate expression, like calling a door *heavy* when we are not attempting the feat of Samson, but merely opening or shutting it, turning it on its well-oiled hinges.

During the present session we have aided ourselves in Glasgow with four very important helps to the teaching of the kinetic system of force-measurement. One is the improvement in nomenclature just referred to. The second is the use of names for the kinetic units of force. The British Association has sanctioned the use of the name *Dyne* for the kinetic unit of force founded on the centimetre, gramme, and second, as units of length, mass, and time respectively. Prof. James Thomson has given the name *Poundal* for the British kinetic unit of force founded on the foot, pound, and second. The third help is the construction by Prof. Thomson, for the first time, so far as I know, of spring balances for indicating poundals and kilodynes. The fourth aid is Dr. Everett's admirable book on the C. G. S. system of units. J. T. BOTTOMLEY

Seasonal Order of Colour in Flowers

I AM very much obliged to Mr. Buchan for his elaborate paper in NATURE, vol. xiii. p. 249, on the Flowering of Spring Plants (see my query, NATURE, vol. xiii. p. 129). Although agreeing with Mr. Pryor that the blue is anticipated by various other colours, yet I think that the method of inquiry by averages is the only basis we can go upon; and that is the plan I have adopted for some time. I have now a carefully-assorted collection of hyacinths, and I see that the blue and white are coming out nearly together, the red showing as yet no colour whatever. What would be the action of light upon blue or red flowers, if the blue or red ray was carefully excluded, if this could be done? Would the flower thrive, and if so, would its colour be much altered? C. E. HERON ROGERS

Retford, Notts, Feb. 7

OUR ASTRONOMICAL COLUMN

VARIABLE STARS.—Herr Julius Schmidt publishes (in *Astron. Nach.*, No. 2,074) the results of observations of variable stars made at Athens in 1875, amongst which the following may be noted:—

1. 34 Bootis, a star to which he had directed attention some years since, as certainly variable though observed with difficulty on account of proximity to ϵ, was found to be at a maximum on April 26—a good determination. In 1872 he assigned a period of 369 days from six observed maxima, commencing 1867, July 31, and as many minima, the first, 1867, November 18. Between the maxima of 1867 and 1875, we should have eight periods of about 353 days. The mean place of this star for the beginning of the present year is in R.A. 14h. 37m. 32s., N.P.D., 62° 54′·1.

2. Mira Ceti. Three curves drawn from comparisons of this star with α and γ Ceti and α Piscium gave the date of maximum, February 27·5, March 1 and 3 respectively, of which the latter is preferred. Calculating from the formula of sines in Schönfeld's second catalogue, the maximum of 1875 is fixed to February 24·2. Observed minimum, October 30.

3. η Geminorum.—The variability of this star was detected by Schmidt in 1865, and has since been confirmed by Schönfeld, who found for the brighter phase small and not very regular fluctuations, but for the minima a regular diminution and increase, the first continuing about six weeks, and the last perhaps rather longer. This is in near agreement with Schmidt's previous deductions. He had found by comparison with μ Geminorum that η at times remained constant for several months about the maxima, of which, writing in 1869, he states he had been unable to assign the dates. In 1875, however, two maxima were noted, Feb. 25 and Sept. 23; showing an interval of 210 days. The period assigned in the last Manheim catalogue is 229·1 days. This star is of a deep yellow colour. Variation between extremes of 3·2 and 4·2.

4. ϵ Aurigæ.—Schmidt collects the results of his comparisons of the relative brightness of ϵ and η Aurigæ, between the years 1843-1875. The star is irregularly variable within somewhat narrow limits.

5. u Herculis.—The principal period appears to be about 38·7 days, but according to Schmidt (A. N. 2,075) the curve exhibits waves of about twelve hours' duration, which are of the greatest depth at the principal minimum, and comparatively shallow at the maximum, and he has given a figure explanatory of what he considers to have been the law of variation between 1875, July 4, and Aug. 29. So unique a case appears to require further investigation.

6. g Herculis.—This reddish-yellow variable was discovered by Mr. Baxendell in 1857, and has been carefully observed by Schmidt. The period, according to Schönfeld, has varied between 40 and 125 days, the star thus resembling in the great irregularity of period the well-known R Scuti, which was discovered by Pigott in 1795. Last year Schmidt's comparisons showed three maxima and two minima, indicating periods 77, 73, and 77 days. The variation extends through little over one magnitude.

7. α Cassiopeæ.—Of this star Schmidt remarks that the fluctuations of brightness in 1875 were not greater than in the cases of other stars, which are not yet placed upon the variable list.

8. T Coronæ Borealis (Nova 1866).—Mostly ninth magnitude, or rather fainter; exhibiting sensible variation, but to very small amount.

9. R Scuti.—Observed maxima on October 12 and December 8 give the short period of 57 days. The period entered in Schönfeld's second catalogue is 71·1 days. There are great irregularities in the case of this star, not only in the period but in the degree of brightness at both maximum and minimum; the former has been noted between 4·7 and 5·7, and the latter between 6·0 and 8·5.

MINOR PLANETS.—No. 131, *Vala*, discovered by Prof. Peters at Clinton, U.S., 1873, May 24, has so far been unsuccessfully sought at Pola and Berlin between limits of − 30m. and + 15m. in respect to the place of the ephemeris apparently founded on Stockwell's elements; the longitude of perihelion in this orbit differs materially from that given by Knorre's earlier calculation, and possibly a misprint or error of transcription may be the cause of the difficulty.—Prof. Tietjen notifies that the ephemeris of No. 141, *Lumen*, in the *Berliner Jahrbuch* for 1878, is vitiated by an error in *Astr. Nach.*, No. 2,030, where ω is substituted for π; the habit of some computers of giving the orbital angle between perihelion and node, instead of the longitude of perihelion itself, is certainly not without its inconvenience, and this is more particularly the case with early orbits of comets.—No. 156, discovered by Palisa, 1875, Nov. 22, has been named *Xanthippe*.—New elements of No. 158 give a period of 1,889 days, or 5·17 years.

THE SATURNIAN SATELLITE, HYPERION.—Observations of this faint object made with the 26-inch refractor of the U.S. Naval Observatory on forty nights between 1875, June 16 and Nov. 25, appear in No. 2,076 of the *Astron. Nach.* It is stated that the observations were generally made with difficulty. Prof. Asaph Hall acknowledges his obligations to Mr. Marth for his ephemerides of the satellites of Saturn, by which he has endeavoured to facilitate identification of these objects, and which could only have been prepared at an expenditure of much time and trouble.

THE DATE OF EASTER

WE revert to this subject with the view to reproduce the arithmetical rule to find Easter Sunday in the Gregorian Calendar, which was first given by the

eminent German mathematician and astronomer Gauss, in Zach's *Monatliche Correspondenz*, 1800.

1. From 1800 to 1899 put $m = 23$, $n = 4$.
   „ 1900 to 2099 „ $m = 24$, $n = 5$.
2. Divide the given year by 19, and call the remainder a.
3. „ „ by 4, „ „ b.
4. „ „ by 7, „ „ c.
5. Add m to 19 times a, divide the sum by 30, and call the remainder ... ... d.
6. Add together n, twice b, four times c, and six times d, divide the sum by 7, and call the remainder e.

Then Easter Sunday is March $22 + d + e$, or
$d + e - 9$ of April.

To apply this rule to the present year, we have—

1. $m = 23 \quad n = 4$
2. For $\frac{1876}{19}$ remainder is 14 . . . . a.
3. For $\frac{1876}{4}$ remainder is 0 . . . . b.
4. For $\frac{1876}{7}$ remainder is 0 . . . . c.
5. For $\frac{23 + 19 \times 14}{30}$ remainder is 19 . . . . . . d.
6. For $\frac{4 + 0 + 0 + 6 \times 19}{7}$ remainder is 6 . . . . e.

And Easter Sunday is March $22 + 19 + 6 =$ March 47 or April 16; or $19 + 6 - 9$ of April = April 16.

NOTE.—The following are the two exceptions to the above rule:—

1. If Easter Sunday is brought out April 26, we must take April 19.
2. If Easter Sunday results on April 25 by the rule, the 18th must be substituted when the given year, increased by one, and then divided by 19, leaves a remainder greater than 11.

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA [1]

II.

THE extinct *Marsupialia*, *Edentata*, and *Ungulata* were treated of fully in the previous course.[2] It is only proposed now briefly to recapitulate the principal results as bearing on the derivative hypothesis, and to call attention to some recent additions to our knowledge of the past history of these groups.

The *Monotremata*, represented only by the *Ornithorhyncus* and *Echidna* of Australia, the lowest and most reptilian of mammals, seem to be the survivors of a group of animals of intermediate structure through which the passage from the lower to the higher vertebrates was made. But of this palæontology has hitherto afforded not the slightest proof. Except some Pleistocene remains of one of the existing genera, no trace of any extinct animal allied to the Monotremata, or showing any decidedly intermediate characters between Mammals and the Sauropsida, has ever been found. The earliest known remains of mammals—in fact, all those of the Mesozoic period—appear to belong to the Marsupialia, although too little is yet known of their general organisation to pronounce definitely on their affinities. As early as the time of deposition of the Purbeck beds, below the Wealden, two very distinct types of dentition prevailed, bearing some resemblance to those characterising the modern polyprotodont and diprotodont types, the one being mainly carnivorous or insectivorous, and the other frugivorous or herbivorous. True Marsupials, allied to the American Opossums, have been found in the Eocene and Lower Miocene formations of Europe, but not later. Many of the recently discovered insectivorous and carnivorous mammals of the North American Eocenes also appear to have been Marsupials, but the Tertiaries of no part of the world, except the Australian Pleistocenes, have yielded forms allied to the Wombats, Kangaroos, and Phalangers, now so characteristic of the fauna of that land.

Palæontology teaches scarcely anything of the past history of the Edentata, an order which might be supposed from the diversity in structure and geographical distribution of the animals now included in it to have occupied a conspicuous position formerly in the fauna of the world. The American gigantic Pleistocene forms, the *Megatherium*, *Glyptodon*, and their allies, are of great interest, but they are all closely related to the existing species of the same countries, and their progenitors have hitherto been sought in vain in the earlier formations of the country. Apparently they formed no part of the Eocene or Miocene fauna of the northern part of the Continent. The European Miocene Edentates, *Macrotherium* and *Ancylotherium*, appear to be more related to the existing Old World forms, but their structure is as yet very imperfectly known.

The difference between the Perissodactyle and Artiodactyle Ungulates was fully established in the earliest tertiaries, beyond which we are not able to trace their history. Recent researches of Leidy, Cope, and Marsh have enabled us to form a tolerably connected idea of the history of both these groups in North America. Before 1869 not a single Eocene Perissodactyle had been discovered in that country; it is now known that while the *Lophiodons* and *Palæotheriums* flourished in the Old World, similar forms ranged through the sub-tropical forests of the regions in which the stupendous mountain ranges of Western North America have since been elevated. None of these appear to be identical specifically with the European forms, and even the generic indications, being often founded only on very limited portions of the organisation, as a few teeth, must be regarded as provisional. The best known forms, *Hyrachyus* and *Palæosyops*, are respectively Lophiodontoid and Palæotheroid. Some are allied to the *Hyracotherium*, one of which, *Orohippus*, seems to connect that form directly with *Anchitherium*. One form only, *Diceratherium*, is Rhinocerotic; it is found in the uppermost Eocene strata of Utah, and gives the earliest indications of this group yet known. It seems to be connected with the lower Eocene *Hyrachyus* on the one hand, and the Miocene *Hyracodon* on the other. In the Miocene period, the Perissodactyles attained a great development of form and size, and the groups became more differentiated, and some of them highly specialised. True tapirs do not seem yet to have been met with. The Palæotheroid and Lophiodont forms had nearly, if not quite, died out, but the more horse-like *Anchitherium* was abundant, and appears to have continued the line from the Eocene *Orohippus* (which had four toes on the fore foot) to the true horses of the Pliocene period. Rhinocerotic forms now became ascendant, being represented by *Dicerotherium* with a pair of lateral horns on the nasal bones, *Hyracodon*, a very generalised hornless Rhinoceros, with the complete number of incisor and canine teeth, and several species assigned to the European genus *Aceratherium*. But the most remarkable of the Miocene Perissodactyles of North America are a number of species of gigantic size, to the first known of which Leidy, in 1853, gave the name of *Titanotherium*, and of which other, or perhaps the same, forms have been named by Marsh *Brontotherium*, and by Cope *Symborodon*. Their head was large and much elongated, as in the rhinoceros; but they had a pair of stout diverging osseous protuberances like horn cores on the nasals or anterior part of

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.) Continued from p. 308.
[2] See Abstracts in NATURE, 1873.

the maxillaries in front of the orbits. Their molar teeth were of a simple Palæotheroid type, and the incisors and canines were very much reduced. Their fore feet had four and the hind feet three short stout toes. These animals which, according to the correct rules of nomenclature, should constitute the family *Titanotheridæ*, became extinct, apparently without successors, in the Miocene age.

In the Pliocene period, *Rhinocerotidæ*, in the form of *Aceratherium* and *Aphelops*, were still abundant, though towards the end of the period they became entirely extinct. True rhinoceroses, like those of the Old World with median horns, have never been met with in America. Remains of tapirs are also found but sparingly, and a great development took place in the various forms of three-toed horses, *Protohippus* and *Hipparion*, which replaced the *Anchitherium* of the Miocene. These in their turn gave way to true horses, of which remains of several species have been found in Pleistocene deposits, and scattered throughout almost every region of the Continent from north to south. These also became entirely extinct before the discovery of America by the Spaniards, a most remarkable circumstance when the fitness of the country for their maintenance, proved by the facility with which the descendants of horses introduced by the invaders have multiplied in a feral state, is considered. The tapir, in several modifications, still lingers in some districts of South and Central America, the sole direct representative of the vast and varied perissodactyle fauna of ages long gone by.

The remains of Artiodactyles in the hitherto explored American Eocenes are very scanty and unsatisfactory as affording indications of their characters. Towards the close of the period only do we find evidences of well-defined selenodont (*Agriochœrus*) and bunodont (*Elotherium* and *Platygonus*) forms. No species corresponding to the European *Anoplotherium*, *Dichodon*, or *Xipodon*, have been discovered. During the Miocene period, however, Artiodactyles of both types abounded in North America. The selenodonts were chiefly represented by *Oreodon*, and the allied earlier and more generalised *Agriochœrus*. These were numerous in species and individuals, but they became nearly extinct by the end of the Miocene, only surviving in the form of *Merychyus*, the most modified form of the group, into the Pliocene. The first indication of the camel-like animals appears in this period in the form of *Poëbrotherium*; also a few of the generalised Pecora are now met with, allied somewhat to *Tragulina*, as *Leptomeryx*, *Hypisodus*, and *Hypertragulus*, the latter a very minute species, but no true deer, *Bovidæ* or even *Traguli*, and no giraffes, *Helladotheria* or *Sivatheria*. The bunodonts were chiefly species of *Elotherium*, and an allied four-toed form, *Pelonax*, remarkable for horn-like lateral processes on its lower jaw, near the symphysis. Peccary-like forms also are now met with. In the Pliocene or Pleistocene periods, except the somewhat problematical *Cosoryx*, founded on some branched horn cores or antlers of a form perhaps allied to *Antilocapra* from the Niobrara Pliocene, all the animals can be assigned to existing families. Of the Suina, all belong to *Dicotyles*, or Peccary (which had formerly a more northern range than at present), or to the allied genus *Platygonus*, no true *Sus*, or *Phacochœrus*, *Babirussa*, or *Hippopotamus*, having been found. Thus the American bunodont Artiodactyles, instead of undergoing great and diverse modifications as did the corresponding animals of the Old World, have been gradually dwindling and contracting to the two closely allied species of Peccary, amongst the smallest and most insignificant of all the pigs, and a very old form, having existed (if teeth alone are sufficient evidence) since the Miocene age. The *Camelidæ*, on the other hand, appear to have flourished, the species being numerous, and the individuals attaining very large dimensions. It is probable, in fact, that the family may have originated here, as a tolerably complete series of transitions have been traced from the Miocene *Poëbrotherium*, through *Procamelus* and *Pliauchenia*, to the modern Llamas, which, though now confined to the south, once overran the North American Continent. If this view is correct, the Asiatic camels must have come into that country by immigration. A few traces of *Cervidæ* have been found in American Pliocenes, but their paucity, compared with the Old World, until the Pleistocene epoch, would lead to the belief that they cannot have originated there, but must have been imported from other lands. The same applies to the hollow-horned ruminants, of which no forms different from those now existing have been found in the fossil state.

(*To be continued.*)

THE EFFECTS OF THE SUN'S ROTATION AND THE MOON'S REVOLUTION ON THE EARTH'S MAGNETISM

WHEN the mean horizontal force of the earth's magnetism for each day of the year has been deduced from well-corrected observations of the bifilar magnetometer, and the results have been projected in the usual way, the curves thus obtained show successions of maxima and minima occurring in some instances at nearly equal intervals and in others abruptly and apparently without law. It has been found that these changes are experienced similarly at all stations where observatories have been placed on the earth's surface; they are therefore variations of the magnetic force of the whole earth. The results now considered, though derived from the observations at a single station, may thus be accepted as true generally for all places.

In the projection of the daily mean forces observed at Makerstoun in 1844, the first and last quarters of the year showed large oscillations of the earth's magnetic force, the maxima occurring near the times of new moon and the minima near those of full moon; the ranges of the oscillations were not equally great, and the oscillation disappeared in the months near midsummer. The mean result for the whole year seemed to show that great changes of the earth's magnetic force were due to the moon's position relatively to the earth and sun; but no explanation could be offered for the apparent irregularities in the lunar action. Eleven years later (in 1857), while discussing observations made near the equator, I became persuaded that the variations in question were really due to the sun's rotation on his axis. The result of a re-examination of the Makerstoun observations gave a mean period of nearly twenty-six days for the most probable duration of the magnetic oscillation.

Astronomers who till then had occupied themselves with the determination of the time of the solar rotation had found for it from 27·3 to 27·7 days. It was difficult, in the face of this result, to suppose that the magnets were better acquainted with the true time of the sun's rotation than the eminent observers, who, with the best telescopes, had watched the movement of the solar spots; and it was suggested that a movement of the sun's magnetic poles might explain the difference of the periods obtained. More recently, however, it has been found that the spots give considerably different times for the sun's rotation, and especially that those nearest the solar equator indicate, as Spoerer has shown, a period of 26·3 days, thus approaching nearly to that obtained previously from the magnetic observations. Dr. Hornstein, director of the Prague Observatory, discovered, independently, nearly the same period from his observations in 1870.

There still remained for explanation the irregularities already noticed in the lengths and ranges of single oscillations. I, on a reconsideration of all the discussions previously made by him, arrived some time ago

at the conclusion that the results obtained for the solar and lunar actions did not exclude each other, but that both sun and moon were concerned in the changes of the earth's magnetic intensity; and that possibly the variations in the character of the single oscillations were due to the sun and moon sometimes acting in the same and sometimes in opposite directions; just as in the case of the oceanic tides, for which the differences would be even greater were the solar more nearly equal to the lunar action.

This conclusion is put to the test; the mean variations derived from the observations for each of two successive years are calculated for periods of 26, of 27·3, and of 29·53 days, the two latter being the times of the lunar, tropical, and synodical revolutions respectively. The variations for each of these three periods corresponding to the positions of the moon and of a given solar meridian for each day of the year are then added together; the sums should represent the total actions of the two bodies for each day, and if no other causes are in question, they should agree with the observed variations.

I have shown that when the calculated results are projected so as to form a red curve, on the same mean line as a black curve representing the observations, the two agree very nearly with each other throughout the two years. The different durations and ranges of single oscillations, and the total disappearance of the latter in certain months, are found to be produced, as was supposed, by the greater or lesser agreement or opposition of the three actions.

These results demonstrate, I think, not only that the sun's rotation and the moon's revolutions produce variations of the earth's magnetic force, but that all the marked variations are really due to these causes.

There appears to be one exception to the generality of this conclusion, in sudden great changes, generally diminutions, of the earth's magnetism, which appear of variable magnitude and apparently at irregular intervals. I have examined these cases, and find that if a considerable diminution of intensity happen suddenly when a given solar meridian is in the same plane with the earth, that a similar sudden diminution generally occurs twenty-six days or some multiple of twenty-six days after, when the same solar meridian and the earth are again in the same plane. In one case the sudden loss of force begins five times in succession at the exact interval of twenty-six days.

If we examine these cases of successive disturbance when a given solar meridian arrives opposite the earth, we are induced to conclude either that the solar action exists only for this position, that is to say, that the earth is its cause; or that the action is continuous, but, unlike light and heat, is propagated only in one direction (or plane); or, which seems more probable, that the medium through which these actions are transmitted proceeds from the sun, is not uniformly distributed around it, nor always distributed in the same way. This idea may aid in explaining many facts in terrestrial magnetism for which hitherto no clue has existed.

We arrive then at the conclusions that the variations of the daily mean magnetic force are due to causes external to the earth, depending on the sun's and moon's motions; that all the principal variations of this force can be calculated approximately for each day in twelve months, on the hypothesis that the actions of these bodies are constant throughout the year for the same positions relative to the earth; and that the great magnetic disturbances (accompanied by the aurora borealis) are due to actions proceeding from certain parts of the sun's surface, since so many of them repeat themselves at intervals of twenty-six days, when the same solar point returns opposite the earth. It appears from other investigations that the sun's rotation produces marked effects on our atmosphere.

J. ALLAN BROUN

PHYSICAL SCIENCE IN SCHOOLS

WE have received the following important communications on this subject:—

Dr. Watts has shown in last week's NATURE, p. 311, how the Regulations of the Oxford and Cambridge Schools Examination Board affect injuriously the interests of science in certain schools, viz., those in which boys have "studied science *instead of* the older well-established subjects of classics and mathematics."

But it is fair to say that these are not the schools which are common in the country, even if they are to be found at all; and the business of the Board was rather to examine effectively what schools profess to teach, than to direct their studies into a new line.

I do not think, or mean to say, that the Board and the headmasters, who are believed to have influenced its regulations, have acted in the interests of science altogether; but the way they have damaged its interests in all the principal schools of the country is not by making it "a refuge of fools," as Dr. Watts suggests.

I will, with your permission, point out how the Regulations affect the position of science at Rugby and similar schools.

The main inducement a boy has to go in for a certificate is to be excused the "Little go," if he is going to Cambridge; or "Responsions," if he is going to Oxford. To be excused any part of the Little go he must pass in Latin, Greek, Elementary Mathematics, and Scripture Knowledge; to be excused the whole of it, he must also pass in Additional Mathematics. And since four subjects are all that is required, these four or five are all that he will take up. To be excused Responsions, he must pass in Latin, Greek, and Elementary Mathematics, and in some one other subject. Naturally, he selects the easiest. This will be French, or Scripture Knowledge, or History, or English, according to his tastes. That the three last of these subjects are easier than any Natural Science is certain. All boys know something of them; they are not wholly new to any boy, and it is at any rate commonly believed here that boys have passed and obtained distinctions in them with very great ease. And boys have probably learned French for the last eight years of their lives.

It follows that boys destined for Oxford who know something of science do not take it up, as it would be profitless to do so, unless it is distinctly easier to them than any other subject they could select as a fourth subject; and boys destined for Cambridge do not take it at all.

It should also be observed that though the examination papers last year were very easy, yet the range they cover is rather large. What does "the Elementary Parts of Inorganic Chemistry" mean? This can only be discovered by a study of the examination papers. And certainly the wording is loose enough to enable the examiners to set harder papers, if it is found that the boys can do them.

The only important alteration in the description of the examination in Natural Science that I would make is a very obvious one, and one that might at once be made if any of the headmasters on the Committee would care to ascertain and represent to the University Board the interests of science at schools. It is to divide Group IV. like Group II., making the present part the elementary subjects, and adding to it an additional subject, viz., a practical examination in analysis (inorganic, qualitative), as necessary to be passed by those who wish to gain *honours* in science. To make this change would at any rate be a guide to a sound opinion on teaching science, though, while the grouping remains as it is, few boys will trouble the examiners.

The study of science at schools has now, it seems to me, entered on a fresh and not altogether unhealthy phase. Ten or twelve years ago there was an outcry for

it, and it was introduced into public schools, and protected, and nursed, and encouraged by scholarships at the Universities, &c. On the whole it got quite as fair play and more favour than could have been expected. Now it is no longer nursed; it is left to find its level. It is protected by regulations against the extinctive power of headmasters, and that is all. Meantime, the methods of teaching it are improving; the supply of teachers is increasing; the number of scholarships at the Universities is quite adequate to the demand for them; and the examinations for them are very good. With these favourable circumstances, and a slowly maturing opinion in the minds of most people that education in science is valuable as a part of training, I think we can afford not to be very impatient at the Regulations of the Universities Board, or at the strict neutrality of headmasters when the interests of science are concerned.

JAMES M. WILSON

May I be allowed a few words with reference to some criticisms passed in last week's NATURE on the Regulations adopted by the "Oxford and Cambridge Schools Examination Board" in regard to science?

I fully concur with the writer (Mr. N. M. Watts) that these Regulations and the two papers printed point to a low standard of scientific knowledge in our great schools. It must be borne in mind, however, that the Board does not issue these Regulations as an ideal scheme of school work, but merely intend them to answer the existing state of the case. With the curriculum of any school they have nothing to do, their function being to appoint examiners to such schools as apply for them, leaving the schools free, within reasonable limits, to choose their subjects.

Now granting Mr. Watts' premises that certificates can be obtained *very cheaply* by taking up two sciences instead of Latin and Greek, this would give an impetus to the study of those subjects in schools, resulting in a large flock of scientific candidates.

Whether this has been the case, the following abstract from the examiner's report of last July shows:—

Subjects.	Number of Candidates offering the subject.	Number who satisfied Examiners.	Number who obtained distinction.

Botany	6	4	—
Phys. Geography and Elem. Geology ...	15	7	—

These results show that the number of candidates offering any branch of science is comparatively very small, only seventy out of a total of 461, of whom only thirty-seven succeeded in satisfying the examiners out of a total of 232; and of these thirty-seven only six succeeded in gaining distinction. These figures show, I think, that in proportion to the time and attention given to science in the schools examined last July, the papers set were neither unreasonably easy nor difficult. I wish especially to point out that increasing the difficulty of obtaining certificates by help of science would tend as far as possible to exclude science from the school curriculum, while retaining a low standard encourages boys who have gained a certain crude scientific culture in the lower forms, not, as is so often the case, to let it drop entirely on reaching the sixth.

It does seem to me therefore wiser to commend the wisdom than to deplore the ignorance of the compilers of these Regulations, who aimed at testing the soundness of the small modicum of existing knowledge, rather than fixing a standard which would have practically acted as a prohibition of science.

In considering the amount of knowledge to be expected from boys of eighteen, we must remember the time usually devoted to science work. The following will, as far as my experience goes, be not an unfair statement of the case. A boy commences Latin and French at about eight years of age, at the same time imbibing the first ideas of Mathematics in Elementary Arithmetic; Greek (or German when it is substituted) at twelve or thirteen, and probably Euclid about the same age; Science seldom, if ever, before fourteen or fifteen. Thus the candidate offering himself for examination at eighteen has given ten years to Latin, six to Greek, and about three to Science, the number of hours in those three years given to Science being certainly less than that given to Greek. This programme would be true of certainly nine-tenths of our public school-boys who offer themselves for the examination, the remaining tenth consisting of boys who at seventeen show a distinct aptitude for Science or Mathematics, and who then drop a large proportion of their classical work and are enabled to devote one-half of their time, or thereabouts, to their special subjects. The complaint might with more reason be urged by the classical boys proper against these specialised boys, who are allowed to gain their certificates too easily. When the necessity arises, the standard will doubtless be raised, perhaps, by a division (similar to that made in the Mathematical Group) into Elementary and Advanced Science, with a provision that only one elementary science can be taken up.

Mr. Watts, in the article referred to, asks, rather contemptuously, whether "the knowledge of the composition of the air, the reasons for belief in the rotundity of the earth, the meaning of the words watershed, dip, &c., is the utmost that can be demanded of a boy of eighteen who has studied science instead of the older well-established subjects of classics and mathematics." I hope I have shown that the standard of the examination papers was not too low for the candidates who offered themselves. With reference to the desirability of the change in our whole system of education to which Mr. Watts refers, I may be allowed to say that there is by no means at present an agreement even amongst science teachers that such a change is desirable. I refrain from opening up this very wide subject, because I feel that the experiment has not yet had a fair trial.

Rugby LINNÆUS CUMMING

THE ORGANIC IMPURITIES OF DRINKING WATER

On Thursday last Prof. Frankland delivered a discourse to the Fellows of the Chemical Society at Burlington House on the detection and analytical determination of the organic impurities in potable waters. He said that the more his inquiries into the influence of water upon the public health had extended themselves the more had he become convinced of the great importance of this application of chemical analysis to the community at large, contending that, in the interests of the public health, the bringing to perfection of this branch of analysis was worthy of the greatest efforts of chemists.

The two chief objects to be kept in view in the analysis of potable water are, firstly, the discovery of the evidence of *past* pollution by organic matter; and secondly, the

quantitative determination of *present* or *actual* organic impurity.

The past history of a water is made out chiefly through the mineral products of oxidation which the polluting organic matters have yielded, and which are still present in the water. As these products are innocuous, it is obvious that if all kinds of organic matter behaved alike under the influence of oxidising agents, such evidence of previous pollution might be safely disregarded; but it is almost superfluous to point out that there are wide differences between various kinds of organic matter in regard to the rapidity with which they combine with oxygen; and of all kinds, that which is organised and living opposes by far the greatest obstacles to oxidation. Now the researches of Chauveau, Burdon Sanderson, Klein, and others, scarcely leave room for doubt that the specific poisons of the so-called zymotic diseases consist of organised and living organic matter, and it is now certain that water is the medium through which some, at least, of these diseases are propagated. It is evident, therefore, that an amount of exposure to oxidising influences which may resolve the dead organic matters present in water into innocuous mineral compounds, may, and probably will, fail to affect those constituents which are endowed with life, and Dr. Frankland adduced, as a striking instance of the persistency of the typhoid poison when diffused in water, the outbreak of a violent epidemic of typhoid fever in a Swiss village through the use of spring water, which, after contamination with the poison, had filtered through nearly a mile of porous earth, but which had nevertheless lost none of its virulent properties. As the typhoid poison is always liable to be present in sewage, and as there is no test for it, except its effects upon man, the discovery of previous sewage contamination in potable water ought to be one of the chief objects of the analyst.

The *actual*, or present, as distinguished from the *past*, polluting organic matter of potable water can only be ascertained from the amount of carbon and nitrogen found as constituents of the organic matter present in the water at the time when the analysis is made. The method of performing this operation, known to chemists as the "combustion" method, was fully described to the Fellows of the Society by the speaker eight years ago. Improvements since made were mentioned, and the following proofs of the delicacy and accuracy of the analytical method were adduced:—

To 100,000 parts of a sample of water, rendered as nearly chemically pure as possible, 1·5572 parts of sulphate of quinine were added. The water was then submitted to the method for determining organic carbon and nitrogen just mentioned. The following data compare the quantities of organic carbon and organic nitrogen thus actually added to the water, with those afterwards extracted in each of two analyses:—

	Present.	Found. I.	Found. II.
Organic carbon in 100,000 parts of water	0·857 part.	0·912	0·904 part.
Organic nitrogen in ditto	0·100 ,,	0·0996	0·098 ,,

To 100,000 parts of a similar sample of water 0·7786 part of sulphate of quinine was added, and the following results obtained on analysis:—

	Present.	Found. I.	Found. II.	Found. III.
Organic carbon in 100,000 parts of water	0·429 part.	0·435	0·442	0·440 part.
Organic nitrogen in ditto	0·050 ,,	0·047	0·048	0·048 ,,

To 100,000 parts of a third similar sample of pure water 0·07786 part of sulphate of quinine was added. On analysis this water yielded the following numbers:—

	Present.	Found. I.	Found. II.	Found. III.
Organic carbon in 100,000 parts of water	0·043 part.	0·047	0·050	0·055 part.
Organic nitrogen in ditto.	0·005 ,,	0·006	0·005	0·006 ,,

The close approximation of the experimental to the calculated numbers is the more striking when it is remembered that the weight of nitrogen *actually determined* in the litre of water used for analysis was, in the last series of experiments, only $\frac{1}{20000}$th of a gramme.

Applied to actual specimens of potable water, the accuracy of the method was tested by the uniformity of results obtained in the following duplicate analyses of the same samples of water:—

		Results of analyses expressed in parts per 100,000. I.	II.
Thames water as supplied to London ...	Organic carbon	0·280	0·285 part.
	,, nitrogen	0·032	0·035 ,,
River Lea water as supplied to London.	Organic carbon	0·231	0·239 part.
	,, nitrogen	0·042	0·042 ,,
Kent Company's water as delivered in London	Organic carbon	0·054	0·056 part.
	,, nitrogen	0·016	0·017 ,,

But as practical illustrations of the trustworthiness of the process, the speaker relied most upon the results of the monthly analyses of the water delivered by the eight metropolitan companies made for the Registrar-General during the last eight years, and embodied in two large diagrams which exhibited, at a glance, the results of nearly 800 separate analyses. One of these diagrams showed, by means of curves, the mean proportions of organic elements (organic carbon and organic nitrogen) in the waters of the Thames and Lea, and compared them with that found in the deep well-water of the Kent Company. It also showed the rate of flow of the Thames nearly opposite Hampton Court Palace, and consequently near the place where the Thames water companies abstract their supplies. This diagram showed how sharply the distinction between these three waters is drawn by the method of analysis. In no instance did the curve representing the average organic impurity in the Thames approach near to that indicating the like impurity in the deep-well water, whilst the curve of organic contamination in the Lea water intersected the Thames curve but thrice, and the deep-well curve only once in eight years; and even these intersections, when closely studied, were found to be striking illustrations of the delicacy of the analytical method.

The second diagram might be regarded as a magnified representation of the first. In it the curve representing the average organic impurity in Thames water was decomposed into five constituent curves showing the organic impurity in the water delivered by each of the five metropolitan water companies which abstract their supplies from the Thames; whilst the corresponding curve of impurity in the River Lea was split into two, one representing the impurity in the New River Company's water, and the other that in the beverage delivered by the East London Water Company. As deep-well water is delivered to London by one company only, the curve representing the minute impurity in this water was the same in both diagrams.

These diagrams demonstrated how faithfully the analytical results recorded, firstly, the well-known superiority of deep well over river water; secondly, the superiority of the water of the Lea to that of the Thames; thirdly, the variations in the three great conditions which govern the intensity of organic contamination in the river waters, viz., heavy floods, small floods when the river is low, and decay of vegetation in autumn; and lastly, the method has shown itself competent to reveal the finer shades of quality in waters drawn simultaneously from the same source, but treated differently by the various companies who manipulate them.

Against these advantages the process of analysis advocated by the speaker involves more trouble and more careful manipulation than are usually bestowed upon what are called "commercial" analyses, and although these drawbacks ought not to be paramount considerations, where such important issues are involved, yet if any other more simple method existed from which trustworthy quantitative information about the organic matter in water could be obtained, the more troublesome process would cease to have a *raison d'être*.

Such a simple alternative method of determining organic nitrogen, but not organic carbon, is now very extensively used by chemists. It is known as the "albuminoid ammonia" method, and depends upon the fact that, by boiling with an alkaline solution of potassic permanganate, most nitrogenous organic bodies are decomposed with evolution of ammonia. From the amount of ammonia so evolved, the proportion of organic nitrogen is calculated. A critical examination of the results obtained by this method conclusively demonstrates that it is incapable of converting into ammonia either the whole, or any definite proportion, of the organic nitrogen of potable waters. Indeed, this is shown not only by the following instances, but also by numerous others in which known quantities of nitrogenous organic matters of known composition were submitted to the process.

Results of analysis expressed in parts per 100,000:—

Artificial Waters containing Peaty Matter.

It is almost superfluous to say that any opinion as to the quality of a sample of water, based upon the albuminoid ammonia obtained, must be entirely untrustworthy.

Dr. Frankland summed up with the following conclusions, to which he had been led by the experiments of himself and others —

1. That the "albuminoid ammonia" process of analysing water affords no evidence whatever of the absolute quantity, either of organic matter, or of organic nitrogen present in potable water.

2. That it does not indicate, even approximately, the relative quantities either of organic matter or of organic nitrogen in different samples of such water.

3. That it affords no indication, either of the presence or of the proportion, of *albuminoid* as distinguished from other nitrogenous organic compounds.

4. That the "combustion" process, though more troublesome, is the only method at present known which affords any trustworthy information respecting the organic matters present in potable waters.

5. That it is the only method which even professes to determine organic carbon in such waters.

6. That the determinations by it of organic carbon and nitrogen are fairly accurate, notwithstanding the very minute quantities of matter dealt with, and that the errors even of a comparatively inexperienced analyst fall far short of the limits which would affect a verdict upon the quality of the water submitted to investigation.

7. That it is the only process which discloses the proportion of nitrogen to carbon in the organic matter of waters, such information being often of prime importance in reference to the origin of the organic matter.

8. That since the improvements which have been made in the mode of evaporating the water to be analysed, the process can now be conducted in any laboratory and with a moderate expenditure of time and labour.

RELATION BETWEEN THE LIMIT OF THE POWERS OF THE MICROSCOPE AND THE ULTIMATE MOLECULES OF MATTER[1]

THE subject which I have selected for my address is the relation between the limit of the powers of the microscope, and the ultimate molecules of organic and inorganic matter. I think I may at all events claim for this question sufficient novelty. Until the last few years the subject could scarcely have been attempted, and even now so many necessary facts are imperfectly known, that nothing more can be done than to fill the gaps with plausible assumptions. This necessarily imparts more or less of a speculative character to some of my remarks; but it appears to me that in his annual address the president of a society cannot do better than endeavour to point out the general bearings of what is already known on some great question, even if for no other object than to prove the need of further inquiry.

Though fully impressed with the imperfect state of our knowledge, yet, even now, the facts are sufficiently definite to indicate, if not to prove, the existence of as wide a world of structure beyond the limit of the power of the microscope, as what has been revealed to us by it is beyond the powers of the unassisted eye.

I propose to divide my subject into three heads—

1. The limits of the power of the microscope.

2. The size of the ultimate molecules of organic and inorganic matter.

3. Conclusions to be drawn from the general facts.

In considering the limits of the power of the microscope, I shall assume that the instrument itself is perfect, and that the invisibility of the objects examined is in no way dependent on the want of the necessary characters. The point to which I particularly wish to direct attention is the limit of visibility depending on the constitution of light, beyond which light itself is of too coarse a nature to allow of our seeing objects distinctly defined. This question has been treated of in an admirable manner by Helmholtz in the jubilee volume of *Poggendorff's Annalen* (1874, p. 573). The conclusion to which he arrives is that the limit depends on the confusion in the image due to the bright interference fringes overlapping the dark outlines of the object. This limit varies directly as the wave-length of the light, and inversely as the sine of half the angle of the aperture of the object-glass when illuminated by means of a condenser of equal aperture. According to this principle the limit for dry object glasses of 60° aperture is, roughly speaking, about equal to the wave-length of the light, and for the largest possible aperture equal to $\frac{1}{2}$ the wave-length. In the case of immersion object glasses of the same aperture, the limit is about $\frac{3}{4}$ of that for dry.

On comparing this theory with the results of observation, the agreement is very striking. It indicates exactly the same law for the increased defining powers of lenses of large aperture, as has been determined by experiment, and gives for the theoretical limit of distinct visibility $\frac{1}{80000}$th part of an inch, which is exactly the same as the mean of the experimental determination of a number of the most skilful microscopists. It also shows why in the case

[1] Anniversary Address of the President of the Royal Microscopical Society, H. C. Sorby, F.R.S., &c. Abstract by the Author.

of lines at equal intervals, like Nobert's bands or the markings on Diatomaceæ, it is possible so to manage the illumination that the dark fringes of interference may coincide with the true lines of structure, and give rise to good definition, even beyond the normal limit, and also agrees with the fact that lines less than $\frac{1}{100000}$th of an inch apart can be *photographed*, though *seen* with extreme difficulty, if indeed truly resolved, except under very peculiar and exceptional conditions; since the waves of light at the blue end of the spectrum, which are concerned in photography, are short enough to give good definition of lines so near together that the interference fringes due to the longer waves at the red end would give an indistinct image. Taking everything into consideration, the agreement between observation and the theory is so close as to make it extremely probable, and to justify the conclusion that the normal limit of distinct visibility with the most perfect microscope is $\frac{1}{2}$ of the wave-length of the light. If so, we must conclude that, even with the very best lenses, except under special conditions, light itself is of too coarse a nature to enable us to define objects less than $\frac{1}{80000}$th or $\frac{1}{100000}$th of an inch apart, according as a dry o · an immersion lens is used. We must also conclude that, *as far as this question is concerned*, our microscopes have already reached this limit, whatever improvements may remain to be made in other respects.

2. *The Size of the Ultimate Atoms of Matter.*

After discussing the results obtained by Stoney, Thompson, and Clerk-Maxwell, mainly derived from the properties of gases, I come to the conclusion that in the present state of our knowledge the best approximation that we can make to the size of the ultimate atoms of matter is the mean of their determinations. I adopt for simplicity $\frac{1}{1000}$th of an inch as the unit of length, and $\frac{1}{1000}$th of an inch cube, or $\frac{1}{1000000000}$th of a cubic inch, as the unit of volume. In the case of a true gas the number of atoms in the length of $\frac{1}{1000}$th of an inch at 0° C., and a pressure of one atmosphere, would be 21,770, and hence, in $\frac{1}{1000}$th of an inch cube, about 10,320,000,000,000.

If this gas were a mixture of two volumes of hydrogen and one of oxygen, on combining to form water there would be a contraction to $\frac{2}{3}$, and on condensing into liquid water a contraction to $\frac{1}{770}$ of this; but since the molecules of the resulting liquid would contain three atoms of the gases, the total number of molecules of liquid water in a given volume would be $\frac{3}{2} \times 770 \times \frac{1}{3} =$ 385 times the number of atoms of a gas. This gives for the number of molecules of liquid water in $\frac{1}{1000}$th of an inch cube about 3,900,000,000,000,000.

As an illustration of a far more complex substance I take albumen, and calculating as well as one can from its chemical composition, and from the specific gravity of horn, I come to the conclusion that the diameter of the ultimate molecule of dry albumen is about 3·82 that of the molecules of water, and that $\frac{1}{1000}$th of an inch cube would contain about 71,000,000,000,000.

If such be the case, we must conclude that in the length of $\frac{1}{80000}$th of an inch (the smallest interval that could be distinctly seen with the microscope) there would be about 2,000 molecules of liquid water lying end to end, or about 520 of albumen. Hence, in order to see the ultimate constitution of organic bodies, it would be necessary to use a magnifying power of from 500 to 2,000 times greater than those we now possess. These, however, for reasons already given, would be of no use unless the waves of light were some $\frac{1}{2000}$th part of the length they are, and our eyes and instruments correspondingly perfect. It will thus be seen that, even with our highest and best powers, we are about as far from seeing the ultimate structure of organic bodies as the naked eye is from seeing the smallest objects which our microscopes now reveal to us. As an illustration, I have calculated that with our highest powers we are as far from seeing the ultimate molecules of organic substances as we should be from seeing the contents of a newspaper with the naked eye at the distance of a third of a mile; the larger and smaller types corresponding to the larger and smaller molecules of the organic and inorganic constituents.

3. *General Conclusions to be deduced from the above facts.*

When we come to the application of these principles to the study of living matter we are immediately led to feel how very little we know respecting some of the most important questions that could occupy our attention. As illustrations I do not think I can select better than the facts bearing on the size and character of minute germs, and on Darwin's theory of ultimate organised gemmules.

For the sake of simplicity I will take into consideration only the albuminous constituent of animals, using the term *albumen* in a sort of generic sense. Whatever be the special variety of this substance, it is so associated with water in living tissues, that in most, if not all, cases they would cease to live, if thoroughly dried. Much of the water is no doubt present simply as water mechanically mixed with the living particles; but it appears to me that we ought to look upon some portion as being in a state of *molecular combination*. The existence of such a state of union is clearly proved by the optical characters of various solutions of the same coloured substance. These are by no means such as would result from the mere mechanical diffusion of very minute particles of the solid substance in the liquid, and cannot be explained unless we suppose that the coloured substance is to some extent in the state of molecular combination with the solvent. This molecular affinity is also in some cases manifested by a swelling up of a solid substance when placed in certain liquids, even when perfect solution occurs to a very limited extent. Such a condition appears to be very characteristic of the living tissues of animals, and makes it very probable that the ultimate living particles are molecular compounds with water, and not molecules of free dry albuminous substances. So little is known of the true proportion of water thus combined, that the only course now open is to suppose, for illustration, that living albuminous matter contains half its volume of water mechanically mixed, and one-fourth of free albumen, united with one-fourth of molecularly combined water. On this supposition a sphere of such living matter $\frac{1}{1000}$th of an inch in diameter would contain the following number of molecules:—

Albumen	10,000,000,000,000
Water in molecular combination .	520,000,000,000,000
	530,000,000,000,000

The very small relative amount of dry matter in some living animals makes it probable that the molecularly combined water plays such an important part in their ultimate structure, that we may base our provisional conclusions on this total number of molecules.

Theory of Invisible Germs.

Calculating then from the various data given above, we may conclude that a spherical particle one-tenth the diameter of the smallest speck that could be clearly defined with our best and highest powers, might nevertheless contain no less than one million structural molecules. Variations in number, chemical characters, and arrangement would in such a case admit of an almost boundless variety of structural characters. The final velocity with which such particles would subside in air must be so slow that they could penetrate into almost every place to which the atmosphere has access.

Darwin's Theory of Pangenesis.

Full particulars of this theory will be found at p. 374 of vol. ii. of his work on the variation of animals. He nowhere gives any opinion as to the actual size of gem-

mules, or the number present in particular cases, but it appears to me interesting to consider how far the theory will hold good when examined from this more physical point of view.

For the sake of argument, I assume that gemmules on an average contain one million structural molecules of albumen and molecularly combined water. Variations in number, composition, and arrangement would then admit of an almost infinite variety of characters. On this supposition it would require a thousand gemmules to be massed together into a sphere, in order to form a speck just distinctly visible with our highest and best magnifying powers. By calculation I find that a single mammalian spermatozoa might contain so many of such gemmules, that, if one were lost, destroyed, or fully developed in each second, they would not be completely exhausted until after the period of one month. Hence, since probably a number are concerned in producing perfect fertilisation, we can readily understand why the influence of the male parent may be very marked, even after having been, as regards particular characters, apparently dormant for many years.

In a similar manner I calculate that the germinal vesicle of a mammalian ovum might contain enough gemmules for one to be destroyed, lost, or fully developed in each second, and yet the entire number not be exhausted until after a period of seventeen years, and the entire ovum might contain enough to last at the same rate for no less than 5,600 years.

These calculations are made on the supposition that the entire mass is composed of gemmules. Of this there is little probability; but still, even if a considerable portion of the ovum consists of completely formed material and of mere nutritive matter, it might yet contain a sufficient number of gemmules to explain all the facts contemplated by the theory of pangenesis. The presence of any considerable amount of such passive matter in spermatozoa would, however, be a serious difficulty in the way of the theory, unless indeed very many spermatozoa are invariably concerned in producing fertilisation.

Taking everything into consideration, it does not appear to me that any serious objection can be raised against pangenesis when examined from a purely physical point of view, as far as relates to the inheritance of a very complex variety of characters by the first generation, though there would have been may serious difficulties to contend with, if the ultimate atoms of matter had been very much larger than is indicated by the properties of gases.

When we come to apply similar reasonings to the second or following generations, we are compelled, along with Darwin, to conclude that gemmules have the power of producing other gemmules more or less closely resembling themselves, and of being collected together in the sexual elements, since otherwise the number that could be transmitted in a dormant state for several generations would be far too small to meet the requirements of the case.

Conclusion.

In my remarks I have made no endeavour to conceal our present ignorance of many very important questions connected with my subject. Want of the requisite data necessarily imparts a speculative character to many of my conclusions; but perhaps there is no more fruitful source of knowledge than to see and feel how little is accurately known, and how much remains to be learned.

THE TUFTED DEER OF CHINA

AMONG the many most valuable additions which Mr. R. Swinhoe has made to our knowledge of Chinese zoology, there are none more important than his discoveries in the deer-tribe. The Water Deer of Shanghai (*Hydropotes inermis*), first described in 1870, is one of the most interesting of these. It is of small size, without horns of any kind, and with long canine teeth present in the males only. In outward appearance it in these respects closely resembles the Musk Deer. Its colour is light chestnut, and the hairy coat is harsh. It is called the *Ke* and the *Chang* by the Chinese. Sir Victor Brooke has demonstrated that its skull differs in important points from that of *Moschus*.

Still more recently, in 1874, Mr. Swinhoe has described another small deer from the mountains near Ningpo, of much the same size as *Hydropotes*; it also resembles that genus in being hornless and possessing large canine tusks in the males. Mr. Swinhoe, in the "Proceedings" of the Zoological Society (1874, p. 452), writes as follows:—"My friend and correspondent, Mr. A. Michie, wrote me a letter dated Shanghai, December 19, 1873, as follows:—'I send another note to overtake the mail, to tell you I have just found a new deer from the Ningpo country. It is a dark iron-grey or pepper-and-salt colour, like some Scotch terriers, with white tips to its ears, square-built (that is, straight back and pointed hip), with very short tail. On its forehead is a thick black mane, like the bristles of a boar. . . . It has the lachrymal sinus, but not so large as the Muntjac; in size the beast about equals the Muntjac.'" An excellent figure accompanies this description. It was drawn from a skin sent by Mr. Michie to Mr. Swinhoe, who has named the animal *Lophotragus michianus*.

A living example of this species, the first ever brought to this country, has just reached the Zoological Gardens in Regent's Park. From this male specimen it can be seen that the drawing above referred to, made from the flat skin, excellently represents the figure of the animal, and is truthful in that it shows the canine teeth and the absence of horns. In the living specimen there is a pair of hair-covered tuberosities on the frontal regions, at the postero-lateral angles of the hairy head-tuft, but, as in the Giraffes, these have no horns upon them. Comparing this condition with that of *Elaphodus cephalophus*, also from China, described by M. A. Milne-Edwards, the intimate relation of *Lophotragus* to the Muntjacs (*Cervulus*) is evident; the series of gradual antler-reduction being in the following order:—*Cervulus*, *Elaphodus*, *Lophotragus*. Whether *Hydropotes*, or *Moschus*, or both are extremes of this series, remains to be proved; and it must be mentioned that it is not perfectly certain, though highly probable, that the above-described individual specimen of *Lophotragus* exhibits its highest degree of antler development.

NOTES

SOME weeks since it was stated that the collection of fishes made by Mr. Francis Day, Inspector-General of Indian Fisheries, would be deposited in the New Indian Museum at South Kensington. It was offered to and accepted by the Secretary of State for India, but it was subsequently considered that neither the expense of bottles in which to exhibit them, nor of spirit for their preservation, could be rightly debited to the resources of India. Mr. Wood, the well-known artist, very liberally proposed, in exchange for the type collection, numbering about 1,200 species, to increase Mr. Day's plates in his work, the "Fishes of India," from 160 to 190, or to 1,140 figures. The Director of the Indian Museum in Calcutta hearing of this arrangement, proposed to the trustees that he should secure it at once on these terms, and we understand that he has been instructed to do so. It will doubtless render the Museum in Calcutta the most complete in Indian fishes in the world; but whether this collection finding a place in the British Museum might not have proved more beneficial to science we leave for the decision of our readers.

MR. WILLETT has just issued a report on the Sub-Wealden boring, stating that the bore-hole has been widened and lined to

a depth of 1,760 feet, and that boring was recommenced on the 8th inst. at a depth of 1,825 feet, when the hard limestone passed into soft shales, and mentions the occurrence of imperfect specimens of ammonites, at 1,849 feet. Geologists will probably not be disposed to agree with Mr. Willett, "that the theory of the presence of a ridge of old rocks north of the English Channel and south of the Thames is no longer tenable," for we believe that no one ever denied that the Wealden axis was "a true anticlinal elevation." In stating that the Cretaceous rocks are the same thickness on both sides of the axis, Mr. Willett appears to forget that the old Palæozoic rocks were contorted and their upturned edges denuded, before the Secondary rocks, much less the Tertiary, were deposited, and in stating that the 1,800 feet of strata, explored by the boring, as well as the overlying beds, were "deposited during a prolonged and continuous subsidence of this part of the earth's surface," we believe few men of science will coincide with him. In the conclusion of his report, he offers personally to bear the cost of any boring in Kent or Sussex, above the Wealden horizon, which may reach the Palæozoic rocks, within a depth of 2,000 feet.

IN answer to Dr. Playfair on Monday, Mr. Cross said the recommendations of the Royal Commission for Scientific Instruction and the Advancement of Science had been for some time under the consideration of the Government. With reference to what steps the Government proposed to take in the matter, he would rather not anticipate, he said, the statement which it would be the duty of his noble friend the Vice-President of Council to make on the subject. We look forward with considerable interest to the statement which Lord Sandon has to make, and hope we shall not have long to wait for it.

MR. WARD HUNT stated last Thursday in the House of Commons that Capt. Nares will send a sledge party down to the entrance of Smith's Sound in the spring of this year, if possible, with despatches, for the chance of a ship from England calling there. The Admiralty have arranged with Mr. Allen Young, who is contemplating a voyage to the Arctic regions this year in his yacht, to look for cairns in which such despatches might be deposited, and he has, with great public spirit, consented to make this the primary object of his voyage, undertaking to bring home any such despatches, unless he can find means for sending them to England otherwise.

A LARGE and influential meeting of the citizens of Glasgow was held on Wednesday, Feb. 16, to make arrangements for the meeting of the British Association on Sept. 6. The Lord Provost presided. The University buildings were granted for the Association meetings. Most of the guarantee fund of 4,000*l*. was subscribed, and resolutions were adopted to extend the hospitality of the city to strangers attending the Association.

THE death of the well-known French engineer, M. Thomé de Gamond, is just announced. M. de Gamond is probably best known as the originator of the Channel Tunnel, and he died on the very day on which the Commissioners took the final steps for the completion of that great work. He was born in 1798 at Paris, but was educated in the Netherlands, where he gave great attention to hydrography. His great scheme was remodelled by him many times before it took its final form. It was brought before several International Exhibitions and Commissions, and he published a great number of pamphlets, documents, and books before the scheme gained the favour of those who were able to help him in carrying it out. He was not destined to see the boring actually commenced, but he saw all obstructions and objections removed. M. Thomé de Gamond had also conceived a vast scheme for the improvement of the streams and rivers of France. He proposed to enable the country to utilise the whole of its hydraulic resources, and was anxious to put an end to the immense loss of water which might be used for irrigation and as a motive power. He was modest, energetic, and benevolent.

THE death of M. Adolph Brogniart, Professor of Botany and Member of the French Academy of Sciences, was announced in Paris on Saturday.

PROF. NILS PETER ANGELIN, Intendent of the Palæontological Department of the Riks Museum, Stockholm, and author of "Palæontologia Scandinavica," died at Stockholm on the 13th inst., aged upwards of seventy years.

THE death is announced of M. d'Orbigny, Assistant Naturalis at the Natural History Museum, Paris.

HERR VON LOEHER has recently read a paper before the Munich Academy of Sciences in which he argues that the Guanch or Wandsch population of the Canary Isles, who for more than a century repulsed all invaders, are the descendants of the Vandals. Most of the names of places are barbarian, but some Germanic. Many common expressions are a mixture of both, and names of persons are almost Germanic, as also religious phrases and the titles of public functionaries. Herr Loeher believes that the Vandals or Goths settled in the Isles in the eighth century, finding there a weak barbarian population whom they subjugated, that they gradually lost the use of iron and shipbuilding, and mostly relapsed from Christianity into German heathenism, but, though degenerating in their complete isolation, retained the features and customs of their race in all essential points until their discovery by Europeans. Fair-haired mummies have been found in their tombs, and the dimensions of the skulls agree with those of Germanic races.

IN a letter to the Vice-Chancellor of Oxford, Prof. Max Müller expresses his great gratification with the decree passed in Convocation on Tuesday week. "It was solely," he says, "in order to secure the leisure necessary for the completion of my labours connected with the ancient literature of India that I came to the decision to resign my professorship. Now that you have in so generous a way granted me that leisure, I look forward with great satisfaction to spending the remaining years of my life at Oxford, and, if my health be spared, I still hope to be able to prove to the members of the University that they have bestowed this privilege on one not quite unworthy of their confidence."

A MAGNIFICENT new map of France has recently been completed by the French Engineering Department, and is now being published in sheets. It is on the scale of 1·500000, and must take the place of all previous maps, most of which are, we believe, inaccurate in many important particulars. By means of various easily understood devices, the new map shows all the main natural and artificial features of the country, and by means of its metrical divisions, the distances of places from each other may be observed at a glance.

A VERY interesting museum will be opened in a few weeks at the village of Castleton, in the Peak of Derbyshire, a place much visited by geologists, &c. It will contain: (*a*) a series of articles of the Bronze and Neolithic periods from Switzerland, Denmark, Cissbury, Yorkshire, with a large number of the prehistoric remains from the tumuli, &c., near Castleton, the result of the explorations of Mr. Rooke Pennington, F.G.S., and Mr. John Tym during the last few years. (*b*) Palæolithic implements. (*c*) A magnificent series of the Pleistocene animals of the Derbyshire district—bison, grizzly bear, reindeer, rhinoceros, hyæna, &c. (*d*) A good geological series, of about 1,500 species of fossils numbering about 3,500 specimens, from Crag to Laurentian, and including a good Ichthyosaurus, Plesiosaurus, Crag and Eocene mammals, some good fish, &c. Most of the formations are well represented, but particularly those prevailing near Castleton (mountain limestone, Yoredale series, and coal

measures). (e) A series of minerals and rocks, the Derbyshire minerals being specially good; and some educational sets of fossils and minerals. All the above are properly arranged with explanatory notes, so as to be useful to the uninitiated and to teach geological rudiments, whilst affording advanced students opportunity of comparing their "finds" and naming them. (f) A series of the fauna and flora of North Derbyshire, including mammals (stuffed), birds, and their nests and eggs, ferns and mosses, &c. (g) Collection of old china, entirely obtained from the older houses in the neighbourhood, with old books, ornaments, coins, &c. (h) Set of archaic mining tools from the old lead mines of Castleton. (j) The natural and commercial productions of the neighbourhood. (k) Geological maps and sections, guide-books, and a small scientific reference library. Mr. Pennington's collections are all included in the museum.

THE investigation into the cause of the explosion at the Jabin pit, near Lyons, in France, seems to show that the workmen were not to blame for any imprudence in the use of their lamps, but that the catastrophe was probably produced by the inflammable air escaping from the coal beds by a great diminution of barometric pressure, which reached 10 millimetres in a few hours. This connection of explosions in mines with a diminution of barometric pressure has been frequently referred to recently in connection with explosions in England. The question has been asked whether it is not desirable to extend the system of storm warnings to coal-mining districts; if the miners could only be induced to attend to them there seems no doubt that a great saving of life would be thus effected.

A VALUABLE and in many respects exhaustive memoir on the temperature of the air at Brussels, by Prof. E. Quetelet, based on forty years' observations ending with 1872, appears in Vol. XLI. of the Memoirs of the Royal Academy of Belgium. The paper presents in a more extended and permanent form the leading features of the most important element of the climate of Brussels, which appeared about a year ago in the form of a small tract, briefly reviewed in NATURE at the time (vol. xi., p. 444).

MRS. MARSHALL HALL, sen., writes that the lady who made a successful ascent of Mont Blanc on the 31st ult., mentioned in our last number, was Miss Stratton, a Welsh lady, not an American.

AN apparatus of great delicacy has lately been devised by Dr. Mosso of Turin, for measuring the movements of the blood-vessels in man. A description of it, with figures, appears in *Comptes Rendus* of Jan. 24. The arrangement of the *plethysmograph* (as it is called) consists in enclosing a part of the body, the fore-arm, *e.g.*, in a glass cylinder with caoutchouc ring, filling the cylinder with tepid water, and measuring, by a special apparatus, the quantity of water which flows out or in through a tube connected with the cylinder, as the arm expands or contracts. An opening in the cylinder is connected by a piece of caoutchouc tubing with a glass tube opening downwards into a test tube suspended from a double pulley with counterpoise to which the recording lever is attached, in a vessel containing a mixture of alcohol and water. When the vessels of the arm dilate water passes from the cylinder into the test tube, which is thereby immersed further, so that the counterpoise rises; in the opposite case water flows back from the test-tube into the cylinder, the test-tube rises, and the counterpoise descends. Among other applications of the apparatus, Dr. Mosso employs it in studying the physiology of thought and cerebral activity. The slightest emotions are revealed by the instrument by a change in the state of the blood-vessels. The entrance of a person during the experiment, in whom one is interested, has the effect of diminishing the volume of the fore-arm four to fifteen cubic centimetres. The work of the brain during solution of an arithmetical or other problem, or the reading of a passage difficult to understand, is always accompanied by contraction of the vessels proportional to the effort of thought.

THE Perthshire Society of Natural Science has recently conferred a great benefit on the City of Perth by drawing attention through one of its members, Dr. Lauder Lindsay, to the many imperfections of its water-supply. Perth, as our readers know, stands on the banks of the finest river in the kingdom, and yet its water-supply is lamentably deficient in quantity and quality. The present system of supply was organised about fifty years ago, and Dr. Lindsay brought it to the test of the universally recognised principles of sanitary science, with the result stated. Unfortunately Perth lies very low, and on that very account unusual care must be taken to keep the supply of water pure. After the lesson which Dr. Lindsay has read the inhabitants, it will be their own blame if they do not exercise what would be genuine economy, and remedy a state of matters which must undoubtedly exercise a deleterious influence on the health and prosperity of the fair city. We think this practice of bringing science to bear on matters of local importance is one quite within the sphere of local scientific societies.

THE Meteorological Commission of Allier have now twenty regular meteorological stations at different heights, varying from 686 to 3,773 feet. These stations, together with eighty others for the observation of thunderstorms, have been established for the investigation of the local climates of the department. It is resolved by the Commission, in the interests of general meteorology, to connect its observations as much as possible with those which are collected at Paris.

THE additions to the Zoological Society's Gardens during the past week include a Bay Bamboo Rat (*Rhizomys badius*) from India, presented by Mr. Jas. Wood Mason; an Anderson's Kaleege (*Euplocamus andersoni*) from Burmah, two Hill Francolins (*Arboricola torqueola*) from India, presented by Mr. W. Jamrach; a Sociable Vulture (*Vultur auricularis*), two Cape Francolins (*Francolinus capensis*) from Africa, presented by Mr. J. C. Hobbs; two White-necked Storks (*Ciconia episcopus*) from India, received in exchange; two White-backed Pigeons (*Columba leuconota*) from the Himalayas, a Tiger Bittern (*Tigrisoma brasiliense*), five Geoffroy's Doves (*Peristera geoffroii*) from South America, purchased.

THE INDUSTRIAL APPLICATIONS OF OXYGEN[1]

II.

WE must now direct our attention to a small group of proposals for extracting oxygen from the air by purely mechanical means, without the aid of any chemical action. They are founded on one or other of two physical principles, diffusion or absorption.

T. Graham, whose "inquiries into the laws of the diffusion of gases" will always be remembered as one of the most perfect of his numerous and great researches, observed in 1866[2] that air drawn through a small fissure of a thin india-rubber leaf contains the constant proportion of 41·6 parts of oxygen to 58·4 parts of nitrogen, so that half of the nitrogen of the atmospheric air is kept back, and that this mixture makes red-hot coals burn with a flame. Deville,[3] however, tested this method with regard to its industrial merits, and found that it required too much time to be considered practical.

Endeavours to utilise absorption have been made in two different ways. Messrs. Montmagnon and De Laire obtained a patent in France in 1868 for a process, founded on the observations of Angus Smith,[4] according to which charcoal takes up more oxygen

[1] Translated, by permission of the editor, from the "Report on the Development of Chemical Industry, in conjunction with friends and fellow-workers, by A. W. Hofmann." The present article, as well as the previous one, it should be understood, are by Dr. A. Oppenheim. Continued from p. 295.

[2] Graham, Compt. Rend. lxiii, 471.

[3] Deville, Wagn. Jahresber., 1867, 216. [4] Bull. Soc. Chim. [2], xi, 261.

than nitrogen from the air. They have found that 1,000 litres of charcoal absorb 925 lit. of oxygen and only 750 lit. of nitrogen. When moistened with water, 350 lit. of oxygen and 650 lit. of nitrogen are given off; so that 575 lit. of oxygen and 55 lit. of nitrogen remain, which may be extracted by means of the air pump. By repeating the same process with this gaseous mixture, they succeeded in obtaining oxygen in almost a pure state. Whether this method was ever employed on an extensive scale is unknown. But this has been the case with Mallet's[1] method, founded on the higher coefficients of absorption of water for oxygen, as compared with nitrogen. The coefficients of absorption of these gases in water are 0·025 for nitrogen, and 0·046 for oxygen. Multiplied by their volumetric proportion in the atmosphere 0·79 and 0·21, these figures yield the proportion in which these gases occur in water = 0·0197 N and 0·0097 O; or, the air absorbed in the water contains in one volume 0·67 N, and 0·33 O. If the non-absorbed nitrogen is now allowed to escape, and the absorbed mixture of the two gases is extracted from the water and submitted a second time to absorption, we shall find by multiplying their coefficients with the numbers just obtained, 0·67 (N) and 0·33 (O), that the mixture now absorbed will contain 0·525 N and 0·475 O. A third absorption will raise this proportion to 0·375 N : 0·625 O; a fourth to 0·25 N : 0·75 O; a fifth to 0·15 N : 0·85 O; that is the same relation in which the gases occur in the mixture ordinarily produced by Tessié du Motay's process. After the eighth absorption, the gas evolved is almost pure oxygen (0·973 O and 0·027 N).

Mallet's apparatus consists of a greater or smaller number of strong iron water-reservoirs, connected by forcing and sucking pumps. Into the first air is pumped through fine openings, at a pressure of about five atmospheres. After this the non-absorbed nitrogen is removed by opening a valve, and then by means of the second forcing and sucking pump the absorbed gas is drawn out of the first vessel and forced into the second. With four vessels a complete operation is performed in five minutes. If the vessels vary in size, decreasing from the first of 10 cb.m. to the fourth of 5 cb.m. in capacity, uninterrupted working will produce a result of 7,760 litres of a mixture containing 75 per cent. of oxygen per hour; or, 168 cb.m. in twenty-four hours. The cost of working and keeping this system in order is said to be trifling, and a small amount of superintendence will suffice if the machine is made automatic. Where working power is cheap, such as water power, or the lost heat of metallurgical processes, these methods might possibly be of use, especially for metallurgical processes themselves, which could be effectually assisted by mixtures containing a smaller proportion of oxygen.

Summing up the practical results of this long list of inventions, we find in the foremost rank the well-established method of Tessié du Motay. The next place is taken by the mechanical method of Mallet, just described; which, however, has not yet met with a practical verification.

We arrive at last at the question, What uses has pure oxygen hitherto served? As the supporter of combustion, we are indebted to it for warmth and light; as a means of respiration, it is the foundation of our lives.

Let us look at it then, from these three points of view. Its metallurgical uses claim our first attention. The important part it has performed in the history of platinum has been already described. We have learned to do without it in lead soldering; hydrogen or coal gas, burnt in air, supplying a sufficient quantity of heat. The example of this industry encourages us to cherish the greatest hopes for its further and wider employment. "Just as gold," says an esteemed metallurgical chemist,[2] "while it was still used in soldering platinum, destroyed its appearance by yellow marks, in the same way white soft solder offends the eye when applied to coloured metals. This unsightliness induced the Society for the Promotion of Industry in Prussia to offer a prize for the discovery of a yellow solder. It would be difficult to solve this question, unless a new easily fusible metal of a red or yellow[3] colour could be discovered. A better chance of success offers in the self-soldering of metals by means of the oxyhydrogen blow-pipe, which has already gained triumphs in the manipulation of two metals of different natures. Is it not possible with this powerful agent, which has succeeded in soldering lead with lead, and platinum with platinum, to solder every other metal and every alloy, just in the same manner; as tin with tin,

[3] For which reason the offer of reward has since that time been withdrawn.

copper with copper, brass with brass, silver with silver, gold with gold, and even iron with iron?

"The probability of such an innovation exists, and there is no question of the tangible benefits to be derived from it.

"We need only picture to ourselves the neatness of a workshop in which soldering is effected by means of a light, elegant gas burner, instead of the soldering iron or forge; the workman remaining uninjured by the glowing heat, smoke, and vapours, able at any moment, by the turning of a cock, to regulate the supply of heat with the greatest nicety. We need but look at the solidity of a soldering which no longer depends on a foreign substance, but is the actual blending together of the two parts, thus saving material and work, as no filing of the soldered part would be required. Such palpable advantages must silence every prejudice, and give a strong impulse to the setting on foot of thorough and persevering researches on this subject."

Since oxygen has become cheap, however, its use has likewise been recommended in that largest branch of metallurgy, the production of iron and steel.

Cameron[1] advises the use of oxygen or enriched air, as produced by Mallet's absorption cylinders, instead of common air from the bellows for high furnaces; and here it will be well to remember that the absorption of oxygen in water has already accidentally contributed to this result, in a manner which leaves room for improvement. Br. Kerl[2] calls attention to the fact that air from water blowing machines is richer in oxygen than common air. Besides, it has already been observed that charcoal, when stored up, burns with increased vigour, because it has absorbed oxygen from the air, and that this forms a valuable assistance in refining iron.[3]

Kuppelwieser[4] recommends oxygenised air for the Bessemer process, and he is of opinion that the price of Tessié du Motay's method need not be greatly reduced to allow the use of oxygen for this purpose. A great future seems here to dawn on the application of oxygen! Nevertheless, we must not omit Le Blanc's[5] objection, that the necessity of using fire-proof materials would render the economical advantages very questionable.

But turn from the metallurgical application of oxygen to its use for illuminating purposes. The discovery of the oxyhydrogen light by Drummond[6] in 1826, and its employment in surveying and for lighthouses, has destroyed every doubt as to the value of oxygen for these purposes. The reduction of the price of oxygen brought it into wider use. This time America led the way.

H. Vogel[7] found oxygen successfully employed in New York in 1870, not only for lighthouses, signals, and ordinary buildings, but also to illuminate the beds of rivers, for the building of bridges, and for various appliances of the magic lantern. The building of the great Brooklyn Bridge over the East River, then in an early stage of construction, was facilitated by twelve oxyhydrogen lamps, which consumed about 2,000 cubic feet[8] of oxygen daily. Instead of chalk cylinders, the more durable zirconium-cones were employed with great advantage, and in the same way the Théâtre de la Gaîté and the Alcazar, in Paris, were lit up with fairy-like brilliancy. In the opera house in New York, a diagram of about ten square metres was thrown on a screen of damp muslin, the lamp placed behind the stage, producing wonderful effects. The magic lantern has with the help of this light become very popular in lecture rooms, for the projection of apparatus, glass-photographs, and drawings, especially since Outerbridge[9] taught us to draw pictures with pen and ink on thin gelatine plates. The effects are easily explained when we remember that the oxyhydrogen gas yields a light sixteen-and-a-half times stronger than the same quantity of ordinary gas would yield.

The daily amount produced in 1870 by the New York Oxygen Company was 30,000 cubic feet (850 cb.m.) The oxygen is sold in iron cylinders (patent of Robert Grant, New York), nine inches in diameter and thirty inches in length, which are filled with oxygen under a pressure of twenty to thirty atmospheres.

[8] In Vogel's Report, cubic metres is printed by mistake.

[9] Morton, Journal of the Franklin Institute, liii. liv. lv. See also Vogel in the passage quoted before

The cylinder is sold at one dollar per cubic foot (35 dols. per cb.m.), including the oxygen it contains under ordinary pressure; the refilling with oxygen costs five cents per cubic foot under the pressure of one atmosphere,[1] a very high price, exceeding the calculation of Kuppelwieser more than twenty-two times. Tessié du Motay tried to apply oxygen to the lighting of streets and public places. The "Places" before the Tuileries and Hôtel de Ville were at that time brilliant with light given off from zirconium-cones under the influence of coal gas and oxygen. The unsteadiness of the flame and its great cost led him to prefer the carburation of hydrogen and of coal gas, by passing the gases through a vessel of heavy hydrocarbons fixed to every lamp before it entered the burner. In this way the Boulevards were illuminated from the Rue Drouot to the Rue Scribe with seventy oxygen burners. But this method was given up, and the preparation of a very heavy gas instead of the usual coal gas was at last resorted to, to be burnt by means of oxygen. In this new form the visitor to the Vienna Exhibition met with it at the railway station, Kaiserin-Elizabeth-Westbahnhof. We are permitted to extract the following description from an unprinted report of Herr Karl Haase, director of the Berlin Gas Company, given before the Berlin Town Council:—

"The appearance of the grounds surrounding the Elizabeth railway station, and of the hall itself, lighted up by a mixture of coal gas and oxygen, is in the highest degree surprising. The effects caused by the little bluish flames are quite peculiar, and cannot be compared with any other light. The green of the trees seems more vivid, the colours of the dresses more brilliant, and, above all, the faces of the people appear clearer, every shade and colour showing almost as distinctly as in full daylight, notwithstanding which the light did not tire the eyes.

"The favourable impression made on entering the grounds is heightened on entering the large second-class waiting-room, where everything, down to the minutest detail of ornamentation, is most distinctly seen by the light of the little flames of only two moderate-sized gaseliers.

"However, the best conception of the new method of lighting is produced in the up-train station-hall. Here, in order to make the comparison more striking, the ordinary platform used by up-train passengers was lighted with heavy gas and oxygen, only half the number of jets being lit as were used on the opposite platform, where the old gas was burning with the aid of oxygen. Notwithstanding the double number of lamps and the good quality of the gas, the space lighted by the new method was incomparably more brilliant. The shadows of the candelabra, and even of the smoky flames, were perceptible on the white walls."

In spite of this favourable impression, Herr Haase comes to the conclusion that the new double gas, conducted in two pipes, is not adapted for general private use, particularly for the following reasons:—"The advantage of its brilliancy is more than counterbalanced by its cost, which in Berlin, taking the usual lighting power as the standard of comparison, would amount to double the price of the ordinary gas: the consumer would not understand the working of the cocks: the oxygen would deteriorate in the long conducting pipes, and the repairs would be expensive, &c. Although for public buildings, for shops, and some other purposes, the new method might answer, it would be impossible to lay down three gaspipes for these limited ends." This opinion stands diametrically opposed to that of Schiele,[2] who warmly recommends the new method of lighting, but it is in close accordance with the opinion stated by Le Blanc,[3] about a year before, in a report to the Town Council of Paris. This report is the result of extensive researches by Messrs. Péligot, Lamy, Troost, De Mondésir, and Le Blanc, appointed a commission for the purpose by the Prefect of the Seine in 1869. They undertook to test the method on the Place de l'Opéra, as well as in the laboratory, by burning with half its volume of oxygen, in separate burners, ordinary coal gas, Boghead gas, and gas saturated with fluid hydrocarbons according to various systems. They came to the conclusion that at equal illuminating powers Tessié du Motay's method is almost always more expensive, mostly twice as expensive, as the usual illumination. Only in one case, where the fluid hydrocarbons of Boghead coal were used for carburation, according to Levêque's method, by saturating wicks with the oil and letting the gas pass over them, the price of the new light appeared twice as cheap as the ordinary method, and that only when large burners were used, and consequently a greater quantity of light was produced.

The calculations were of course founded on the data furnished by the Tessié du Motay Gas Company respecting the prices of oxygen, of the carburation, &c. In truth, however, it appeared that in the last-named experiment 1 cb.m. of gas, instead of taking up 50 gr. of fluid hydrocarbons, as the company pretended, actually absorbed 266 gr.; and thus the economy, to say the least, became very questionable. As to the lighting power, it was possible to increase it so as to form three to seven times the power of ordinary street-burners. But Boghead gas can also produce three times the quantity of light, in suitable burners, without having recourse to pure oxygen, and for general purposes such an intensity of light is not desired; on the contrary, the light is lessened 30 per cent. by globes or shades. The Commission came to the decision, therefore, of advising the Corporation of Paris not to authorise the laying down of oxygen pipes, but rather to leave it to the company to supply oxygen and carburetted coal-gas in portable vessels to the comparatively few who stand in need of such an increased intensity of light.

The results arrived at in Brussels were no more favourable. During the last year lighting by oxygen was tried for a short time in some cafés, as well as in the Passage St. Hubert, and then discontinued[1] on account of the aforesaid objections. In Vienna, in April 1874, the Westbahnhof was still lighted with oxygen, but the system had spread no further; for in spite of its intensity and acknowledged beauty, the bluish moonlike light did not produce anything like a general satisfaction.[2]

The jury of the Vienna Exhibition inspected the oxygen lighting at the Westbahnhof. In the Exhibition building itself, oxygen industry was not represented.

If further experiments confirm the above opinions, the industry of oxygen will have lost the root from which it commenced to grow, because wherever it has sprung up it was fostered by the hope of being employed for illuminating purposes.

Many of the alleged disadvantages, especially the cost of the laying down of pipes, are avoided in the arrangement which Philipps[3] proposed for oxygen lighting. According to this proposition lamps (manufactured by George Berghausen, of Cologne) were to be fed with very heavy tar oil containing naphthalin, whilst oxygen was introduced through the middle of the wick. It is, however, very doubtful if any larger city would renounce the advantages of gas-light in favour of this arrangement, and consequently, if there is any chance of its application on a large scale.

Let us be all the more hopeful that oxygen industry will find its saving ally in metallurgy.

In medicine it has won no friend. Up to the present time there is nothing to contradict Pereira's opinion[4] in spite of many more recent praises of the medicinal powers of oxygen,[5] and we can therefore do no better than quote it anew:—

"Soon after the discovery of oxygen, its therapeutical application was in great favour. The want of a proper supply of oxygen to the body was considered to be the cause of many diseases, such for example as scorbute, and it was asserted to have been used in many cases with brilliant success. Beddoes[6] and Hill employed it in England. The latter declares that he found it useful in cases of asthma, weakness, ulcer, humor albus, and scrofulous bone diseases.

"These opinions have nevertheless been greatly modified on chemical, no less than on physiological grounds. In cases of asphyxia, caused by want of air, or by inhaling noxious gases, the respiration of oxygen may possibly be useful. For this reason it has been administered in cases of asthma threatening suffocation. But as the patients in such cases are scarcely able to inhale it, if it acts at all, it can only act as a palliative, and is decidedly incapable of preventing fresh attacks. In most cases where oxygen has been inhaled it was therefore powerless to help; and from the physical reasons stated above, very little success can be anticipated from its employment.

5 Verbal communication of Prof. Dr. Oscar Liebreich.
6 "Considerations on the use of factious airs, and on the manner of obtaining them in large quantities." By F. Beddoes and J. Watt. Bristol, 1794-95. There was a Pneumatic Institute established in Bristol in 1798, in which the medical properties of gases were tried, and it was here Humphry Davy discovered the effects of protoxide of nitrogen.

"This did not prevent medical speculators from opening an institution in Berlin for inhaling oxygen, where it is now being sold at 7*d.* the cubic foot, while oxygen water is sold at 2*d.* the bottle. As water of 0° does not absorb 4 per cent. of its volume, a half-litre bottle contains less than 20 cb.m., or 0·0017 grammes of this gas! It seems incredible that such a dose should be expected to produce any effect whatever. Just as travellers are recommended to provide themselves with concentrated food, those who wish to climb the highest mountain tops, or by means of balloons reach great heights, where the thinness of the atmosphere might cause them dangerous inconveniences, are advised to use pure oxygen as a concentrated means of respiration.[1] P. Bert[2] exposed himself and others in proper apparatus, to degrees of rarefaction of air, which far surpassed that of the greatest heights ever reached by man. The want of breath and symptoms of suffocation which ensued, when the barometer stood at from 300 to 250 mm., were, according to his account, at once relieved by one breath of pure oxygen. A mixture of the same with atmospheric air proved even more effectual than the pure gas, and, on an aërial voyage which the late MM. Crocé Spinelli and Sivel undertook from Paris on the 22nd of March, 1874, they provided themselves with mixtures containing 45 and 75 per cent. of oxygen to 55 and 25 per cent. of nitrogen. They were enabled by the help of this gas to make valuable physical observations,[3] at heights of more than 6,000 metres, leisurely and without any bodily inconvenience; and although Glaisher had succeeded in reaching still greater heights without this assistance, oxygen offers a means of gaining strata hitherto inaccessible."

These words, however, were scarcely written when the newspapers announced the death of the courageous navigators on a new aërial voyage; suffocation appears to have set in so suddenly as to incapacitate them at once from using their respiratory apparatus.

The physiological applications of oxygen form the bridge to some considerations on the practical uses of ozone, the discovery of which had been greeted by exaggerated hopes.

A. OPPENHEIM.

SOCIETIES AND ACADEMIES

LONDON

Chemical Society, Feb. 17.—Prof. Abel, F.R.S., president, in the chair.—The president announced that Mr. James Duncan had presented the Society with a most life-like and spirited marble bust of Dr. Hofmann. He then called upon Prof. Frankland to deliver his lecture "On some points in the analysis of potable waters." A report of this we give on another page. —A full discussion of the variation in purity of the water supplied during the past eight years by the various London companies followed, illustrated by most excellent diagrams, and the lecturer concluded by pointing out some of the objections to the other well-known processes employed for water analysis.

Zoological Society, Feb. 15.—Prof. Mivart, F.R.S., in the chair.—Mr. Sclater exhibited the parrot called in Tschudi's "Fauna Peruana" *Conurus illigeri*, and observed that it had been certainly wrongly determined. Mr. Sclater was of opinion that the bird belonged to a species hitherto unrecognised, and proposed to call it *Ara couloni*, after M. Coulon, of Neuchatel, who had sent the specimen for exhibition.—Dr. Cobbold, F.R.S., exhibited and made remarks on a Parasite (*Echinorhynchus*), obtained from the Tamandua Anteater, which had died in the Society's menagerie.—Mr. W. K. Parker, F.R.S., read the second portion of his memoir on Ægithognathous Birds.—A communication was read from the Rev. O. P. Cambridge, in which he described a new order and some new genera and species of Arachnida from Kerguelen Island, from specimens collected by Mr. Eaton during the Transit of Venus Expedition.—Mr. G. French Angas communicated descriptions of four new species of land shells from Australia and the Solomon Islands, which he severally proposed to name *Helix moresbyi*, *Helix ramsdeni*, *Helix beatrix*, and *Helix rhoda*. Mr. Angas also made some remarks on the nomenclature of *Helix angasiana* of Pfeiffer, and *Helix bitæniata* of Cox.—Mr. Sclater read some notes, by himself and Mr. Salvin, on some of the Blue Crows of America, taken from specimens lately examined, and pointed out certain changes which it would be necessary to make in the nomenclature of the group adopted in their "Nomenclator Avium Neotropicalium."

Geological Society, Feb. 2.—Mr. John Evans, F.R.S., president, in the chair.—Edward Richard Alston, David Corse Glen, Thomas Vincent Holmes, William G. M'Murtrie, Charles Bine Renshaw, Robert Drysdale Turner, and George Ferris Whidbourne, were elected Fellows of the Society.—Evidence of a carnivorous reptile (*Cynodrakon major*, Ow.) about the size of a lion, with remarks thereon, by Prof. Owen, F.R.S. The specimens described by the author consist of the fore part of the jaws and the left humerus of a reptile obtained from blocks of Triassic (?) rock from South Africa, forwarded by the late Mr. A. G. Bain. The upper jaw displays a pair of enormous canine teeth much resembling those of *Machairodus*, being of a very compressed form, with the hinder trenchant margin minutely toothed. There is no dentated border to the fore part of the crown. No teeth can be detected in the alveolar border of the right ramus of the lower jaw, which extends about an inch behind the upper canine. In the symphysial parts of the lower jaw the bases of eight incisors and of two canines are visible, the latter rising immediately in front of the upper ones, to which they are very inferior in size, and being separated by a diastema from the incisors. In this character, as in the number of incisors, the fossil resembles *Didelphys*; and in structure both canines and incisors resemble those of carnivorous mammals. The left humerus is 10½ inches long, but is abraded at both extremities. It presents characters in the ridges for muscular attachment, in the provision for the rotation of the forearm, and in the presence of a strong bony bridge for the protection of the main artery and nerve of the forearm during the action of the muscles, which resemble those occurring in carnivorous mammals, and especially in the Felidæ, although these peculiarities are associated with others having no mammalian resemblances. The author discusses these characters in detail, and indicates that there is in the probably Triassic lacustrine deposits of South Africa a whole group of genera (*Galesaurus*, *Cynochampsa*, *Lycosaurus*, *Tigrisuchus*, *Cynosuchus*, *Nythosaurus*, *Scaloposauras*, *Procolophon*, *Gorgonops*, and *Cynodrakon*), many of them represented by more than one species, all carnivorous, and presenting more or less mammalian analogies, for which he proposes to form a distinct order under the name of Theriodontia, having the dentition of carnivorous type; the incisors defined by position, and divided from the molars by a large laniariform canine on each side of both jaws, the lower canine crossing in front of the upper, no ectopterygoids, the humerus with an entepicondylar foramen, and the digital formula of the forefoot, 2, 3, 3, 5; 3 phalanges. The author further discussed in some detail the remarkable resemblances presented by these early reptiles, in some parts of their organisation, to mammals, and referred to the broad questions opened out by their consideration. He inquired whether the transference of structures from the reptilian to the mammalian type has been a seeming one, due to accidental coincidence in species independently created, or whether it was real, consequent on the incoming of species by secondary law. In any case the lost reptilian structures dealt with in the present paper are now manifested by quadrupeds with a higher condition of cerebral, circulatory, respiratory, and tegumentary systems, the acquisition of which, the author thought, is not intelligible on either the Lamarckian or Darwinian hypotheses.—On the occurrence of the genus *Astrocrinites* (Austin) in the Scotch Carboniferous Limestone Series, with the description of a new series (*A. ? Benniei*), and remarks on the genus, by Mr. R. M. Etheridge, jun. The author, in his introduction to the paper, commenced with a general history of the genus *Astrocrinites* of Austin, commenting upon the change of name it had received from the several authors who had written upon and noticed the species *A. tetragonus* of Austin. In 1843 Major T. Austin described this aberrant Echinoderm under the name *Astrocrinites*, assigning its geological horizon to be the Carboniferous Limestone, and locality Yorkshire. Dr. H. G. Bronn rejected the name *Astrocrinites* on account of its resemblance to *Asterocrinites* of Münster, and proposed instead that of *Zygocrinus*. Römer, from the four-rayed structure of our *Astrocrinites*, allied it to the Cystoidea rather than to the Blastoidea. Prof. de Koninck, and M. le Hon, however, referred *Zygocrinus* to the Blastoidea, and stated their reasons for so doing. Prof. Morris, in 1854, altered Austin's *Astrocrinites* into *Astrocrinus*, and does not notice Bronn's name, *Zygocrinus*. Prof. Pictet provisionally referred the latter genus structurally to *Codonaster*,

noticing, however, its four instead of five pseudambulacra. The author then notices at some length the species he proposes to call *A. Benniei*, which appears to differ much from Austin's *A. tetragonus*. The body or calyx of *A. Benniei* is tetraradiate, having four convex lobes, three of which are alike, the fourth differing considerably from the others, the deep re-entering angles between the lobes are occupied by the pseudambulacra, the dorsal surface is densely covered with closely-set tubercles, but shows no point of attachment, the ventral surface is flattened, having a large central aperture, from which radiate the four pseudambulacra; excentric as compared with the ambulacral system is a second and pyriform aperture of complex structure. The component parts are then minutely described, followed by careful descriptions of the pseudambulacra, apertures, and ornamentation, also a discussion as to the presence of a madreporiform tubercle. The second part of the paper treats upon the affinities of *A. Benniei* (Ether.) with *A. tetragonus* (Austin). Part the third enters fully and critically into the systematic position of *Astocrinites* amongst the Cystoidea and Blastoidea. In the concluding and fourth portion of the paper, the localities and geological horizons are given. Twenty-seven figures, occupying three plates, accompanied the paper.—On the genus *Merycochœrus* (family Oreodontidæ), with descriptions of two new species, by Mr. G. T. Bettany, B.A. Communicated by Prof. T. McKenny Hughes. An account was given of remarkable vertebrate tertiary skulls and other remains brought from Upper Oregon by Lord Walsingham, in 1872, and presented by him to the Woodwardian Museum, Cambridge. The characters of the family of Ungulates (Oreodontidæ), to which they belong, and of the genera of the family, were referred to, and supplemented from examination of these remains. The genus *Merycochœrus*, previously known only from teeth and portions of jaws, was further defined and described from large skulls and portions of skulls. The remarkable size of the temporal fossæ, the form of the zygoma, and especially its great posterior transverse crest, are special points of interest. Finally two new species, *M. temporalis* and *M. Leidyi*, were defined and described.

Meteorological Society, Feb. 16.—Mr. H. S. Eaton, president, in the chair.—Frank C. Capel, Zophar Humphreys, Edward Mawley, Rev. George H. Mullins, William H. Watson, and C. Theodore Williams were elected Fellows of the Society.—The following papers were read:—On an improvement in aneroid barometers, by the Hon. R. Abercromby. The improvement consists in jewelling the ends of the arbor of the index hand like the ordinary pivots of a watch, and making the hand work under the cap instead of in the usual manner. The advantages gained are: (1) increased sensitiveness; (2) increased definiteness of the indications; and (3) diminished influence of weather on the bearings.—Meteorology in India in relation to cholera, by Col. J. Puckle, M.S.C. The author in this paper lays before the Society some facts in connection with several serious outbreaks of cholera in different parts of the Mysore country during the last fifteen years, and draws attention to the similarity of the abnormal meteorological conditions that existed on each occasion. Except in a few of the largest towns in India there are no sewers, and no sewer gas proper. Even in these exceptional towns the drainage is incomplete. The general sanitary arrangements are of the most primitive character. In the rural districts the inhabitants adhere to the Mosaic law, in so far that they go forth to the fields, but they do not carry the "paddle" with them for the purpose that was the exponent of the "dry earth" system; *that* necessary portion of the work is left to the drying action of a powerful sun, to the kites and other carrion birds, and, *horribile dictu*, to the pigs and poultry that afterwards are doubtless turned into food. In this way it is not difficult to conceive that sewage of the direst and most unadulterated kind may possibly be taken into the system through poisoned meat, or during rainfall it may find its way to open reservoirs or wells; from which two sources the inhabitants depend for their water supply. At other times during the hot, dry weather, when no rain falls, malaria may arise and be distributed through the agency of the atmosphere. Notwithstanding all that has been said and done, the clue to the mystery of the origin of the disease remains undiscovered. It is the same with the treatment. Remedies that at one time appeared to be most effectual have, at another, most signally failed. Even during the same attack, the same remedy that cured one person would fail in another, even where the same conditions apparently existed. Failure of the usual rainfall at the proper time, and abnormally high and harsh temperature, have been concurrent with several attacks in Mysore and Southern India. At such times the open reservoirs or lakes and wells are much below the usual spring level, and any contamination received at such a time is obviously much less diluted, and more harmful. The author then gives an account of several attacks that have come under his own personal knowledge, which shows beyond doubt that the disease has been arrested by change of air and surroundings, and that ordinary sanitary practice has prevented a possible outbreak. After referring to the recent outbreaks at Bangalore and Madras the author says that everywhere the same story is told of the occurrence of cholera coincident with long absence of rain and a temperature abnormally high.—On sixteen months' rain at Bristol, by W. F. Denning.

Entomological Society, Feb. 2.—Sir Sidney Smith Saunders, C.M.G., vice-president, in the chair.—Mr. McLachlan directed attention to an article by M. Flaminio Baudi in the *Petites Nouvelles Entomologiques*, respecting the habits of *Cychrus cylindricollis*, which he had taken on Monte-Codeno, feeding on the body of a snail (*Helix frigida*). into the spiral of which the beetle was enabled to enter by means of its long prothorax. Some interesting remarks were made by Mr. Bates and others on the peculiar structure and habits of the insect, which appeared to have been found only on a very sterile portion of the plateau of the mountain, and in no other part.—A valuable paper was communicated by Dr. D. Sharp, entitled "Contributions to an Insect-Fauna of the Amazon Valley (Staphylinidæ)." Of this important group of Coleoptera, 487 species were enumerated as inhabiting the valley, of which 463 were described as new; suggesting forcibly how little is really known of the Staphylinidæ of Tropical America. Dr. Sharp also stated that he had devised a method of covering and hermetically sealing the type specimens which, he believed, would accomplish their almost complete preservation, and that he hoped soon to be able to publish a description of the method. The author concluded with remarking on the great importance of certain sexual characters in distinguishing the species.

Institution of Civil Engineers, Feb. 15.—Mr. Geo. Robt. Stephenson, president, in the chair.—The paper read was on estimating the illuminating power of coal gas, by Mr. William Sugg, Assoc. Inst. C.E.

EDINBURGH

Royal Society, Feb. 21.—Prof. Kelland, vice-president, in the chair.—The following communications were read:—On the structure of the body-wall in the Spionidæ, by Dr. W. C. M'Intosh.—On circular crystals, by E. W. Dallas.—Preliminary note on the flame produced by putting common salt in the fire, by C. M. Smith; communicated by Prof. Tait.

THURSDAY, MARCH 2, 1876

THE GOVERNMENT SCHEME OF UNIVERSITY REFORM

THE speech of Lord Salisbury in the House of Lords on Thursday evening, on introducing a Bill for regulating the reform of Oxford University, will probably satisfy the expectations with which the declaration of the Government policy has been awaited. It is a fortunate circumstance that the conduct of the measure should be placed in the hands of one who is, at the same time, Chancellor of the University, a minister in whom both his party and the country have entire confidence, and also a well-known friend of the physical sciences. The Government scheme, therefore, is introduced under favourable auspices; and, in itself, so far as it has been yet revealed, it seems calculated to disarm all opposition. It is true that much yet remains to be learned concerning the modes in which the scheme is to operate. The names of the Commissioners, to whom a certain degree of control is apparently to be entrusted, will be looked for with anxiety; and the details, which will only be understood when the bill is printed, will also be of much interest to those who will be directly affected by them. But the general public, who are after all the party most concerned, is contented with the enunciation of principles which Lord Salisbury's speech contains. He argued, with great ingenuity, that it is not possible for Parliament to dictate to the University and College authorities the precise lines of reorganisation along which they are to proceed. This argument suggests much that a party critic may object to as involving an abnegation on the part of Ministers of their own proper responsibility. However that may be, it is certain that people at large are totally incapable of giving an intelligent approval to anything more definite than the proposals which Lord Salisbury has sketched. Indeed, it may be doubted whether the absence of complete knowledge to which Lord Salisbury himself pleaded guilty, though it may somewhat surprise and disturb Oxford residents, will not have the effect of bringing him into closer harmony with the general feeling of the country. The case for reform does not rest upon minor matters of detail which require research to discover and particular experience to appreciate, and of which the meaning might be altogether altered by further research and wider experience. The plain statement of the facts is enough, and upon that plain statement Lord Salisbury has wisely relied.

The collective revenue of the Oxford Colleges, after making certain necessary deductions, amounts to something over 200,000*l.* per annum; and as the number of undergraduates is less than 1,000, it follows that the average income per undergraduate is a little more than 200*l.* a year. It is important that this estimate should not be interpreted as if it meant the average cost of educating each undergraduate, as Lord Salisbury has not sufficiently guarded himself against the possibility of this confusion. The real meaning of the calculation is to indicate forcibly that at the present time endowment is out of all proportion to educational efficiency. Looking at the figures from another point of view, we find that, out of the total endowments, Fellowships of one kind or another take just one-half or 100,000*l.* Of this sum, again, Lord Salisbury estimates that "idle Fellowships," or those to which no duties are attached, absorb from one-half to four-fifths. There is thus left a balance of from 50,000*l.* to 80,000*l.* a year, which is admittedly not devoted to academical purposes. It is important to recollect that this calculation comes to us upon the authority of Lord Salisbury. The late University Commission, rigidly limiting itself to its immediate functions, merely presented a general account of the income and expenditure of the Universities and their Colleges, and did not attempt to estimate the number of non-resident Fellows, or even to suggest what proportion of the endowments were unremuneratively expended. But this large sum is far from being all that University reformers will have to deal with. Lord Salisbury states that there must be added no less than 123,000*l.* per annum, which represents the probable augmentation in the rents of the College estates within the next fifteen years, as ascertained by the Commission of Inquiry presided over by the Duke of Cleveland. A yet further addition is suggested by Lord Salisbury, arising from the appropriation to educational purposes of certain ancient trust-funds vested in the Colleges, which are now misapplied. Of the amount of this latter source of income, it is impossible to give even an approximate guess. Lord Salisbury carefully refrained from hinting at any specific trust; and it is doubtful whether there are, at Oxford at least, any misapplied trust-funds of any magnitude, except perhaps the Hulsean endowment connected with Brasenose College. Lord Salisbury seems rather to have been glad to take the opportunity of stating his views with regard to the general question of modifying old endowments, than to have referred to any changes of practical importance. It is noteworthy, however, that his views entirely coincide with those expressed by Lord Derby before the University of Edinburgh last December; and thus the two most influential members of the Conservative Ministry are found in agreement upon a policy which has sometimes been claimed as the peculiar heritage of the Liberal party. Whatever may come from minor trusts, the whole available surplus of the endowments at Oxford may be fairly estimated at about 200,000*l.* a year. This sum, of course, is not at the present moment ready for distribution; but it is the amount which, allowing for vested interests and the slow processes of change, Lord Salisbury appropriates to the purposes of his scheme of reform.

That scheme itself has only, as yet, been indicated with very vague touches; but enough has been said to satisfy all reasonable hopes, and to encourage us to wait confidently for the filling-in of the details. In the first place, Lord Salisbury proposes to restore to the University, so far as money can do so, her ancient pre-eminence over the Colleges. The demands of the University for buildings and for professors are to be supplied out of the forfeited "idle Fellowships." "It may be wise to maintain a few of these latter, limiting the holding of them to a certain number of years; but I do venture to lay down that all the University wants, in the shape of museums, libraries, lecture-rooms, and the proper payment of teachers, should be provided for, before the subject of furnishing incomes to men who do nothing can be enter-

tained." The second principle enunciated by Lord Salisbury is the endowment of research—a principle which has been long advocated in these columns, but which now for the first time appears destined to obtain legislative sanction. In the case of its distinguished sojourner, Prof. Max Müller, the University of Oxford has already admitted its duties in this matter; and now research in the physical sciences, under the ægis of Lord Salisbury, and with all the authority that Parliament can lend, will put in its claim to be "made a part of the regular and recognised machinery of the University." To many persons this will be thought the greatest novelty contained in the speech, and it is significant that none of the three peers who followed the mover made any allusion to it in their brief remarks. But it is not necessary now to expatiate upon the importance of the proposal, or the valuable results that will flow from it. It is the first fruits of the Royal Commission on the Advancement of Science, and will lead, we trust, to the adoption of more of the recommendations made by that laborious body. It is of more importance on this occasion to call attention to a distinction which Lord Salisbury has apparently drawn, and to which the Colleges would do well to take heed. If we understand his words aright, he would impose upon the University the duty of supplying, of course from the College endowments, the capital sum that will be required "from time to time for buildings and apparatus, necessary for the purposes of research;" while he would leave to the individual colleges "to provide for the maintenance and benefit of persons of known ability and learning, who may be engaged in study or research in the realms of art and science." This distinction seems to us an important one, partly because it assigns to each the functions which they can best perform, with the least revolution in their characters; and still more because it insists upon two separate modes of endowing research, which are of equal value, and must be both demanded alike. We cannot forbear quoting at some length the comprehensive views of Lord Salisbury on this subject:—"We are of opinion that the mere duty of communicating knowledge to others does not fulfil all the functions of a University, and that the best Universities in former times have been those in which the instructors, in addition to imparting learning, were engaged in adding new stores to the already acquired accumulation of knowledge. There are new sciences which have gained, and which are pressing for, admission to the Universities, and I think no one can doubt that it is for the interest alike of the students and of the nation at large that such sciences should have full encouragement. . . . What I am particularly anxious for is that all branches of culture should have equal encouragement, and should be regarded, not as rivals, but as allies in the great and difficult task of cultivating and developing the human mind." Apart from these two leading features of the Government scheme of University Reform—the endowment of the University by the Colleges, and the endowment of Research—it remains only to notice the ease with which Lord Salisbury, in one short sentence, brushes aside "the religious difficulty" as unworthy of attention. "The teachers at Oxford are not clergymen now, and if we want to get the best men, we must get them from other sources than that which formerly supplied them."

With regard to the machinery by which these great reforms are to be effected, it is better that criticism should wait until fuller explanation is given. On a first glance, it would seem that the colleges are to be allowed a year and a half to devise their own schemes of reform, subject only to the approval of the Commissioners. On this point we confess to a feeling of distrust of such "permissive legislation;" and are disposed to adhere to the old-fashioned liberal theory, which had its advocate in the Archbishop of Canterbury. "He believed that the Colleges are not an exception to the general rule which has been found to exist everywhere, that hardly any corporation was capable of entirely reforming itself without external pressure." It should never be forgotten that some colleges have already tried their hands at reform, and that none have yet made adequate provision for the wants of the University or of scientific research. The College which, in all educational matters, is usually recognised as the most efficient, has obtained final sanction to a scheme which does not allude to either of these subjects. Another college imagined but a few years ago that it was reorganising itself in accordance with the most modern ideal, when its teaching staff obtained permission from their episcopal visitor that they might one and all incontinently marry, and bought off his natural opposition by agreeing to retain all the existing clerical restrictions. It is whispered, at the present moment, that a third college has just matured a scheme by which each of the tutors shall receive a fixed salary from endowment of 800*l*. per annum. With these instances in view, it will manifestly be the duty of all sincere reformers to urge that the powers given to the Commissioners should be strong enough to override the possibility of such abuses. If only this be done, and if the name of Cambridge be added to the bill, the Government project will become in all respects praiseworthy.

LEGISLATION REGARDING VIVISECTION

In our observations last week upon the Report of the Vivisection Commission, we remarked that some might be inclined to think that in the legislative measures recommended Science has made too great concessions to popular feeling, and a more careful perusal of this bulky volume tends to convince us of the correctness of this opinion. One of the most astonishing things referred to in the whole report is the small number of persons for whose restraint the new law is to be passed. Judging from some of the statements made by opponents of vivisection, one would think the vivisectors in this country must be counted by hundreds; but the Commissioners inform us that, on the contrary, not more than fifteen to twenty at the utmost are systematically engaged in the performance of experiments on living animals. They add, however, that experiments are, there is little doubt, occasionally performed by private persons, of whose number they can form no accurate computation. As there might be many such, and their experiments taken collectively might give good grounds for the belief that vivisection is extensively carried on in this country, we have tried to gain some information on this point from the statements of various witnesses. The Society for the Protection of Animals liable to Vivisection has published a pamphlet containing such extracts from the Report of

the Commission as tend to justify the position taken up by the Society, leaving the advocates of vivisection, as it tells us in a prefatory note, to give publicity to such parts of the evidence as favour their views. We have selected the witnesses quoted by this Society as giving evidence upon the extension and abuses of vivisection, in order that we might not run the risk of being misled by partial statements and of under-estimating the extent to which the practice prevails in this country.

The first of these, Dr. Acland, observes that the number of persons in this and other countries who are becoming biologists without being medical men is very much increasing; but beyond this statement, in which he appears to have in view professional physiologists rather than occasional experimenters, there is nothing in his evidence to lead to the belief that vivisection is practised to any extent by the latter class. Mr. G. H. Lewes tells us that so far from ignorant people exercising their fancy in cutting up live animals, even medical students are extremely reluctant to perform experiments at all on account of the trouble involved in doing so. Sir William Ferguson states that the impression on his mind is that experiments are done very frequently in a most reckless manner; but when we look for the grounds of this belief we cannot find anything except the accounts given by students of experiments they had seen during lectures. We should have thought a man of Sir William's experience would not have trusted to such hearsay evidence without farther investigation, knowing, as he must do, how students delight to exaggerate and to tell frightful stories of the dissecting-room for the pleasure of seeing their mother's or sister's eyes grow wide with horror at the tale. The evidence of other witnesses shows that such exaggeration must have been practised here, and that no such experiments as Sir William describes have been performed in any medical school in this country. But this witness is of opinion that it is only in laboratories and schools that vivisection is carried on, as in this country surgeons do not employ it for the purpose of acquiring dexterity, and he thinks there is not much amateur physiology. Such evidence from an active opponent of vivisection goes far to show that the number of occasional experimenters cannot be great, and that the practice of vivisection is almost entirely confined to the fifteen or twenty persons alluded to by the Commissioners. Small as this number is, we would have considered it right to legislate if anything like wanton cruelty had been shown to be practised by them; but the Secretary of the Royal Society for the Prevention of Cruelty to Animals admits that he does not know a single case of the sort, and that in general English physiologists have used anæsthetics where they think they can do so with safety to the experiment. Such being the case, it seems to us that the objections raised to legislative interference by several witnesses carry great weight. Those made by Mr. John Simon are especially worthy of consideration, not only on account of his well-known ability and clear-sightedness, but because his official position has given him a better opportunity of becoming acquainted with the working of laws and of forming a correct judgment regarding the probable operation of any proposed bill than other witnesses who are constantly engaged either in the laboratory or with the cares of practice. The opinion he expresses that incompetent experimenters, careless of the sufferings they inflict, do not exist as an appreciable class in this country, is borne out by the evidence we have already referred to, and it does seem hard that physiologists of high reputation and unblemished character should be treated as a dangerous class, and should be licensed and regulated "like publicans and prostitutes under the licensing system;" Mr. Simon considers that it would afford facilities for the persecution of physiologists, and would enable those who are so inclined to hold them up individually to popular odium. That the inclination is not wanting is shown by the advertisements of the Society for the Abolition of Vivisection constantly appearing in the daily papers. In these an attempt is made to destroy whatever medical practice the authors of the "Handbook for the Physiological Laboratory" may have, and by thus reducing their means of livelihood to starve them as far as possible. This is done by representing them as so hardened by their pursuits and so callous to suffering as to be unfit for attendance at a sick-bed; although we learn from the evidence of Prof. Rolleston and Mr. Simon that two of them at least are exceedingly kindhearted men, and the other two have devoted themselves to researches having an unusually direct bearing on the prevention of disease or the alleviation of suffering.

Much and careful consideration is therefore wanted lest in the endeavour to prevent abuses which may hereafter creep into the practice of vivisection of animals we do not afford facilities for the mental vivisection so graphically described in the evidence of Mr. G. H. Lewes, of honourable, kind-hearted and sensitive men, whose pursuits are not merely advantageous to science but productive, as the Report clearly shows, of great benefit, both to the human race and the lower animals. Legislation may still be wanted in the interests of physiologists themselves, not less than of the animals on which they experiment, but what we have said is, we think, sufficient to show that this must be undertaken in no hasty spirit.

MISS BUCKLEY'S HISTORY OF NATURAL SCIENCE

A Short History of Natural Science, &c. By Arabella B. Buckley. (London: John Murray, 1876.)

THE object of this book is, as stated in the Preface, "to place before young and unscientific people those main discoveries of science which ought to be known by every educated person, and at the same time to impart a living interest to the whole, by associating with each step in advance some history of the men who made it."

We are also told that—

"When treating of such varied subjects, many of them presenting great difficulties both as regards historical and scientific accuracy, I cannot expect to have succeeded equally in all, and must trust to the hope of a future edition to correct such grave errors as will doubtless be pointed out, in spite of the care with which I have endeavoured to verify the statements made.

"As the size of the book makes it impossible to give the numerous references which would occur on every page, I have named at the end of each chapter a few of the works consulted in its preparation, choosing always in

preference those which will be useful to the reader if he cares to refer to them."

This last sentence fully accounts for the character of the work. We may say at once that we have not read it through. Our readers will probably soon see why. But we may get a good idea of its contents by dipping in here and there. Geologists do not require to break a mountain down into road metal in order to discover its structure. The book is by no means a paste and scissors production; it is evidently the outcome of very considerable mental exertion, not only in reading, but in thinking. But, unfortunately, the author seems to have accepted as equally trustworthy guides some of the best and most authoritative works extant, and along with them some, often of the trashiest, volumes of the popular scientific literature of the day. In several, especially of the earlier chapters, the first class of works is mainly referred to, in others the second; a few chapters are based upon a mixture, consequently the result is extremely curious and instructive, at least to the scientific critic.

As a whole, the work is decidedly superior to any of the popular ones on which part of it is based; though of course, as they have to a certain extent leavened it, it is in many places not only inaccurate, but positively astounding in its misrepresentations. It is quite easy, however, to trace in each case the more extraordinary blunders to their popular scientific source.

Recent British popular scientific works, at least since we have lost such masters as Faraday and Herschel, have, in general, one or other of two marked characteristics. The honest but ignorant man, too ignorant to be aware of his own ignorance, complacently and in good faith writes preposterous nonsense. Our author has wisely let *him* alone.

Other quasi-scientific men are acute enough to know, perhaps even to admit to themselves (but only under the strictest seal of secrecy) their own ignorance. Sometimes they may condescend so far from their pedestals as to seek assistance from those who are really competent to give it, but even then they do not save themselves. The true critic easily perceives by a single loose word or phrase which such writers cannot refrain from adding to the accurate periods of their mentor (if only to save their own consciences on the question of originality) the true state of the case.

When the quasi-scientific writer feels diffidence in asking assistance, he gets out of his difficulty by adopting what has been well called the "cuttle-fish dodge," and bewilders his readers by squirting in their faces a cloud of inky verbiage. Our author has trusted too implicitly to *him*.

Our readers must now have a notion of what seems to us, at least, the character of this book. The style is clear and good, and many of the incidental remarks and comments are happy. The early chapters, referring as they do mainly to subjects little treated by the modern popular science writers, are, as a rule, very much superior to the later ones, and in many places may be not merely passed as satisfactory, but even highly commended. For instance, the discovery of the law of compression of gases such as air, at constant temperatures, is, for once in a popular book, actually assigned to Boyle himself, though even here the pernicious influence of the popular quasi-scientific writers has asserted itself in the unwarrantable introduction of the perpetual Mariotte. There are some very sensible remarks on Werner and Hutton, and we are glad to see that William Smith's geological labours are heartily recognised. But what shall we say of passages like the following?—

"We owe to him [Scheele] the discovery of chlorine; and of manganese, barytes, fluor spar, and many *other earths* whose names I cannot expect you to know."

Or this—

"The determination of nitrogen completes the history of the discovery of those gases of which *fire*, air, and water are composed; but you will have noticed that we have not yet arrived at the new explanation of chemical changes which was to take the place of 'phlogiston.' The fact is that Black, Bergmann, Cavendish, Scheele, and Priestley, were all so cramped by the old theory, that though they discovered the facts they could not make the right use of them. *The* man who did this, and who laid the foundation of modern chemistry, was the celebrated French chemist, Lavoisier."

We have taken the liberty of italicising two words in each of these extracts.

Again, Fresnel "found that [Dr. Young] also had the same idea [interference], and this led to a number of experiments, by which they proved at last that the waves in a natural ray of light do not move *merely* up and down like waves in a pond, but also from side to side; and that when light is polarised this complex vibration is destroyed and the waves of each separate ray move only in one direction." The italics here are in the text!

From the later chapters we make but two extracts; these will, we fancy, be thought quite sufficient:—

"If the water were free [in Joule's paddle experiment for the determination of the dynamical equivalent of heat] it would pass on into the air and we should lose sight of it; but the water is shut in and the force cannot escape, so now it employs itself in dashing to and fro all the little particles which make up the water, and producing the effect we call heat; and as it produces exactly 1° Fahr. of heat by the time the 1 lb. weight has fallen 772 feet, we say that *772 foot-pounds of force equals 1° Fahr. of heat.* You might easily prove to yourself in a somewhat unpleasant way that the force is there; for if you were to go on turning the paddle violently for many hours, and there were no means for the heat to escape, the motion of the particles would be so violent against the sides of the boiler that it would burst."

Here again the italics are not ours; but the whole passage shows clearly that the author has read this part of the subject in works in which scientific terms are used loosely or even inaccurately; while difficulties have been avoided, not explained. For when "we say that 772 foot-pounds of force equals 1° Fahr. of heat" we commit so many and such astounding blunders that it would be altogether impossible to enumerate them them all in such a notice as this.

Let us, however, do what we can in a few lines to point out a few of them. Suppose them put as questions by a teacher employing this work as a text-book.

1. What is a foot-pound of force?

To this question the late William Hopkins, perhaps the ablest instructor whom Cambridge ever produced, would have at once replied, "The old story; the height of King's College Chapel in acres!" When *will* our elementary writers at last recognise that a force may b

represented by so many pounds' weight, but *cannot possibly* be represented by so many pounds' weight overcome through so many feet?[1]

2. What is 1° Fahr. of heat?

One might just as correctly ask, "What is 1 oz. troy of time?" We have heard of degrees of temperature, and of quantities of heat, but we are totally unable to conceive what could correctly be designated by 1° Fahr. of heat, though it is clear that it is here used for "the quantity of heat which can raise the temperature of a pound of water by 1° F." But let us proceed to our final extract:—

"If you have understood this explanation, you will have some idea of the theory that heat is altered motion; but to complete the history we require not only to turn work into heat, but also to turn heat into work. This had already been done many years before by a French engineer, M. Carnot, though he did not understand its real significance, but it has now been most beautifully proved by a long series of experiments made by M. Hirn, of Colmar, in Alsace. What M. Hirn practically did was to find out how much heat can be obtained from a ton of coals, and then to find out how much work was performed in an engine by that amount of heat. This was by no means a simple task, for much heat is lost in various ways in passing through the engine; and even when he thought he had allowed for all this, it was found that some of the steam had turned back into water on its way, and thus used up some of the heat. At last, however, when all was carefully measured and calculated, he found that *for every pound of water heated 1° F., enough work had been done to raise a weight of 1 lb. to a height of 772 feet.* This, you will notice, was exactly the converse of Joule's experiment, and proved that exactly as much motion is produced by means of confined heat as there is heat produced by means of checked motion."

This is certainly very novel information. We have hitherto been accustomed to think that "What M. Hirn practically did was [not] to find out how much heat can be obtained from a ton of coals," but to find how much of that heat disappeared by having been actually converted into useful work in an engine.

But enough has been said to show the necessity for the correction of those "grave errors" alluded to in the second extract made above from the Preface.

As to the chronological table with which the volume concludes, and which is carried on to 1874, we would only remark that it would not have been unduly extended if a little space could have been found for even a bare mention of a few such names as Andrews, Forbes, Graham, Stokes, Thomson, and Clerk-Maxwell in our own islands, and a few more like Helmholtz, Foucault, Plücker, and Weber abroad. Surely such names should have been caught at the very first cast of a net whose meshes were found small enough to seize Drebbel, Franklin, Celsius, Reaumur, Fahrenheit, and Humboldt!

[1] We can hardly blame our author for this blunder, great as it is, when we find substantially the same in a recent work by so learned and careful a writer as Guthrie. In § 129 of his "Magnetism and Electricity" we are surprised to read that a body falling to the ground "will, just before reaching the ground, have acquired a MOMENTUM, which is equal to the WORK done in lifting it." The small capitals are ours—and they but faintly express the agony with which we peruse such a passage.

HASSALL ON FOOD

Food: its Adulterations and the Methods for their Detection. By Arthur Hill Hassall, M.D. (London: Longmans, 1876.)

THIS book is practically a new edition of the author's former work on "Adulterations Detected in Food and Medicine;" the main difference being, at least so far as the plan of the work is concerned, that in the present volume it has been thought judicious to exclude the articles on drugs, which occupied indeed a very subordinate position in the older one. We cannot but commend the discretion thus shown: unsatisfactory as are many of the processes employed by the public analyst, viewed as methods of precision, none are more so than those applicable to the analysis of pharmaceutical preparations. It is probably to this fact that we must attribute the immunity from the raids of the inspectors which the apothecaries have on the whole enjoyed; otherwise we must assume that a higher standard of commercial integrity prevails with our druggist than with our grocer or milkman, a supposition to which, possibly, the milkman and the grocer would demur.

Despite the omission referred to, the present volume is nearly double the size of the former one; the increase in bulk may indeed be taken as commensurate with the increase in importance which the subject has of late years assumed. The additional matter comprises articles on the Function, Quantity and Preservation of Food, and on the influence of the utensils employed in its Preparation and Storage: on Unwholesome and Diseased Meat; and on Water and its Impurities A considerable quantity of fresh analytical work has been incorporated, and the author has been at the pains to test the greater number of the various methods commonly employed in the detection of adulteration, and in the determination of its amount. In one or two instances, as for example, in the determination of milk-residues, he is scarcely just to his contemporaries. The chemistry on the whole is fairly good; thanks to the cooperation of Mr. Otto Hehner, whose assistance Dr. Hassall freely acknowledges. But we are inclined, in common, we are sure, with those who have attempted to make absolute alcohol, to doubt that this liquid is best prepared by digesting spirit of 90 per cent. with well-dried chloride of calcium (p. 795). It is well known that calcium chloride unites with alcohol to form a compound in which the alcohol plays the part of water of crystallisation, and which is only decomposed with difficulty. Much is said respecting the composition of "fusel oil" and "potato spirit," although neither the author nor his *collaborateur* thinks it necessary to indicate anything with respect to the existence of isomerism in the alcohols mentioned. On p. 676 we see Payen and Chevallier's analysis of hops given: on the following page precisely the same analysis is repeated as indicating the composition of crude lupulin, which we are further informed, amounts in good samples to about one-sixth of the weight of the hops.

The public generally, and Messrs. Allsopp and Co. in particular, will be alarmed to learn that the water used in the brewery of that eminent firm contains 7·65 grains of sulphate of zinc to the gallon! In the face of such a statement it is hardly sufficiently reassuring to be told that "the water is remarkable for its complete freedom from organic matter" (p. 681). The memory of the strychnine "scare" in connection with the national beverage has scarcely died out: we trust that Dr. Hassall will be the first to allay our anxiety as to the existence of white vitriol in our "pale," and "Burton."

A considerable section of the book is devoted to the

subject of wine and its adulterations ; for much on this matter the author is indebted to the valuable work of Thudichum and Dupré. The question of "plastering" meets with due consideration. This time-honoured operation (it appears to have been practised by the Greeks and Romans) consists in adding finely-powdered plaster of Paris, or sulphate of lime, to the must in the proportion of about 40 lbs. of the plaster to a butt of must, with the view of separating out the vegetable acids in the grape-juice, and thereby, in the opinion of our author, substituting "for the healthful and beneficial tartrates, a bitter and aperient salt"—sulphate of potash. The wines more particularly subjected to this process are sherry, port, and certain French and Greek wines. It appeared to Dr. Hassall "that any process whereby the sulphuric acid can be removed and the original tartaric acid restored, and in the form in which it previously existed, namely, as a tartrate of potash, is highly desirable, and would improve greatly the flavour and quality of all wines which had been plastered, and increase very considerably their money value." Accordingly he has devised such a process in conjunction with Mr. Hehner, and has obtained for it provisional protection with the intent to take out a patent: it consists in treating the wine with tartrate of barium, with occasional shaking, for three or four days. "At the end of this time all but the normal quantity of the sulphuric acid of the wine is precipitated as sulphate of barium, while the tartaric acid is restored in exactly the same amount in which it was originally present; this, uniting with the now liberated potash, gives rise once more to the formation of tartrate of potash, the most characteristic saline constituent of all genuine wines." This "deplastering" process may have all the virtues which its authors claim for it, but since barium salts are in the highest degree poisonous, we, at least, should prefer that our sherry retained all its aperient qualities unimpaired, rather than it should be manipulated with compounds of that element.

In reading this book the question has more than once occurred to us: What must be its effect on the non-professional mind—or indeed on the mind of anybody who, with the view of extending his notions of the principles of alimentation, takes it up for an hour or so in the evening? He will find that the water he drinks may be swarming with *Scenedesmus quadricauda*, *Navicula sphærophora*, and numerous other "living organisms," whose names and appearance are equally distracting; he is told that the tea which he adds to it may be largely composed of the leaves of *Chloranthus inconspicuus*, or of "lie-tea," a vile compound of tea-dust, foreign leaves, sand, and oxide of iron, the whole occasionally coated with "Prussian blue, turmeric, China clay, or other white mineral powder." The sugar with which he sweetens the infusion may be infested with the *Acarus sacchari*, which, he is informed, belongs "to the same genus as the *Acarus scabiei*, or itch-insect, than which, however, it is larger, and possessed of an organisation still more formidable." The milk which he adds to it may be "blue" not merely as he is content to believe through the machinations of the vendor, but from the presence of what the author in one place, following Fuchs, calls *Vibrio cyanogeneus*, and in another place *Oidium lactis*, or *Penicillium*. The question whether fungus or vibrio pales into insignificance before the fact that milk of this kind gives rise to "gastric irritation" or "severe febrile gastritis." His bread may contain *Penicillium glaucum*, or *Oidium orantiacum*; or it may be made from flour harbouring *Uredo segetum*, or *Puccinia graminis*, or it may contain the poisonous darnel, the symptoms produced by which, as he learns from a quotation from Pereira, "are two-fold: those indicating gastro-intestinal irritation—such as vomiting and colic; and those which arise from disorder of the cerebro-spinal system—such as headache, giddiness, languor, singing in the ears, confusion of sight, dilated pupil, delirium, heaviness, somnolency, trembling, convulsions, and paralysis." After this, such commonplace sophistications as alum, bone-earth, and mashed potatoes, can have no terrors for him. His butter, as indeed we learnt from a recent case referred to in NATURE (vol. xiii. p. 242), may be made from other products of the cow than milk, and even his modest rasher may have death lurking in its folds in the form of *Cysticercus cellulosus* or *Trichina spiralis*, concerning which he is told that the former finding its way into the intestines, "there fixes itself by its little hooks, and quickly grows, joint after joint, into a tape-worm;" and that the latter is the cause of "frightful disorder, killing about 50 per cent. of its victims in terrible agony." No wonder that some of us make a 'poor' breakfast; the marvel is that so many of us survive the dreadful meal. We can only account for the fact that numbers are known to exist and even to thrive on such food on the supposition that, like physostigma and atropia, the horrible things we eat act antagonistically and mutually obviate evil consequences: a supposition which we commend to the notice of Dr. Fraser; or it may be, and with equal probability, that the 'living organisms' devour each other, like the Kilkenny cats, and leave no trace, not even their tails, behind them. We refrain from recounting the horrors which may await us at luncheon and at dinner. Even Dr. Hassall is merciful; it was with a profound sense of relief and satisfaction that, turning to the end of the book, we discovered, on the strength of numerous certificates published by him, that some articles of food are, as a certain noble lady should have been, actually above suspicion, although, unfortunately, many of these articles rejoice in fanciful names which hardly serve to recommend them to prudent matter-of-fact housewives, doubtless long ago inured to the all-prevalent adulteration. Dr. Hassall no doubt considers himself a scientific man; but there are cavillers who deem it an act of questionable taste that he should have appended to his book a series of advertisements extending over fifty pages, the greater number of which contain reports issued from his "Analytical Sanitary Institution." We are inclined, however, to look on the matter from what is doubtless Dr. Hassall's point of view, that having made existence scarcely tolerable to some of us by the revelations which it was his duty to make, it was simply an act of kindness to indicate how we might eat our daily bread (to ask for which would otherwise be a mockery) in peace and comfort, even though it should consist of Infants' Food and Angostura Bitters. T.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Prof. Tyndall on Germs

I AM very glad I wrote to you putting my questions to Prof. Tyndall. It has drawn from him a letter, full of all sorts of hints and prophecies and information and pleasant observations on details with which I had not thought of troubling him; and there is even a delicate bit of flattery for poor me, of whom the Professor knows nothing. It is really quite a gem of a letter, a beautiful example of that "tour piquant" referred to by M. Pasteur, which the Professor gives to everything he touches, and which we at home know how to value as well as any Frenchman. There is only one fault in it, and that is that the Professor, in the exuberance of his kindness, has unfortunately forgotten to answer my modest questions. But why does he liken himself to Horatius, and talk of enemies yet to be dealt with? Horatius did not sing his pæan before going into battle. And how can Prof. Tyndall have any enemies? I thought that scientific investigators were all brothers. I regarded Prof. Tyndall as a brother keeping a bright look out due north, and Dr. Bastian as a brother with his eye firmly set towards the south, while Dr. Sanderson seemed to me to be a remarkably silent brother gazing somewhere about sou'-sou'-west-and-by-south-a-quarter-south.

But to be serious. Briefly put, the situation seems to be this.

Prof. Tyndall has propounded a theory—no mere speculation raising a trifling controversy to be settled privately with Dr. Sanderson or Dr. anybody else, but a momentous theory on which, as he says, "the lives of men depend," and the truth of which it concerns all men to sift. It is not addressed to any scientific coterie, but widely published for the benefit of the outside world, the like of me among the rest.

The theory as propounded stands or falls with the assertion that when, with due precautions, an organic fluid is boiled for a few minutes in a flask, which is then hermetically sealed, it is impossible to obtain bacterial putrefaction.

What Prof. Tyndall declares to be impossible, that Dr. Sanderson declares that he has done.

If Dr. Sanderson is right there is an end of the theory, and the lives of men must rest on some other basis.

If Prof. Tyndall is right, Dr. Sanderson (not to put too fine a point upon it) has blundered in his very careful experiments.

Anxious to know where I should look for the truth, I ventured to ask Prof. Tyndall which alternative he adopted. Instead of helping me out of my difficulty he has responded with a flourish of rhetoric about not crossing swords with Dr. Sanderson. It is plainly from no want of courtesy that Prof. Tyndall has declined to satisfy my curiosity. He can't help being courteous; and to the class to which I belong—simple students who hang upon the lips of Professors for their scientific sustenance—he invariably overflows with courtesy.

I am sure he would have answered me if he could.

Even now I should be grateful (and so I believe would many more of us outsiders) if on second thoughts he should resolve to put his rhetorical sword into the unadorned scabbard of common sense, and kindly try to answer three plain questions:—

1. Does he accept Dr. Sanderson's experiments, and give up his theory?

2. Does he reject Dr. Sanderson's experiments as untrustworthy, and why?

3. Can he suggest any third view which will reconcile his theory with established facts?

Unless Prof. Tyndall feels constrained by his regard for human life to give me a reply, I will not press him to do so, if it would be in the least embarrassing. Only, if there is to be an answer, I hope this time it will be direct to the point. Perhaps, after all, it is not absolutely necessary. Silence is sometimes more eloquent than speech.

Feb. 19 INQUIRER

[This letter was unavoidably delayed last week.—ED.]

The Mechanical Action of Light

IN his recent lecture at the Royal Institution upon the Mechanical Action of Light, Mr. Crookes stated that his investigations into this subject had enabled him to measure the repulsive force of light, and he calculated that the sun's light exercised a repulsive force upon the surface of the earth of 3,000 millions of tons, a force sufficient, he said, to drive the earth into space, were it not for the attraction of gravitation.

Let us look for a moment at this conclusion of Mr. Crookes. Granting that gravitation and a (hypothetical) tangential force cause the planets to revolve round the sun, the continuous action of a repulsive force emanating from the sun and impinging upon the surfaces of the planets, would cause them to spin round upon their axes just as a ball spins round when it is propelled along a resisting surface. This rotation would be in the same direction—right to left—as the revolution of the planetary bodies in their orbits.

But such an explanation of the rotation of the planets upon their axes will not, unfortunately, hold good, as upon this hypothesis their axes ought to be perpendicular to their orbits, whereas, with the exception of Jupiter, the equators of the planets are largely inclined to their orbits. If, then, the rotatory movement of the earth is not caused by the friction of a repulsive force emanating from the sun, it is clear that the effect of the 3,000 millions of tons which Mr. Crookes says continuously press against that half of the earth's surface which is exposed to the sun's rays, would be to retard not only the earth's diurnal rotation, but also its annual movement round the sun. Now there is no evidence whatever of retardation from any such cause, either as regards the earth or the planets with whose movements we are most familiar.

I do not in the least question that under certain circumstances light may repel solid, liquid, or gaseous bodies, and, indeed, if Mr. Crookes' general conclusions be confirmed, it may be found that the rapid extension of the tails of comets as they approach the sun may be due to the repulsive action of the sun's rays. As this force would be inversely as the square of the distance, the effect of the sun's light, acting in a straight line upon the highly attenuated matter of which a comet's tail is composed, would repel it with enormous velocity in a direction opposite to the sun as the comet approached its perihelion.

Manchester, February GEORGE HICKS

Metachromism and Allied Changes

THE laws of metachromism, enunciated by Mr. W. Ackroyd (in his recent paper read before the Chemical Society, NATURE, vol. xiii. p. 298), have an apparent parallel in the order of colours shown by various series of combinations; there being but few exceptions to the following rule, in its application to binary compounds. *Increase of the electro-negative element produces a colour change towards the red end of the spectrum, and* vice versâ. Thus the sub-oxides are generally blue, and the per-oxides yellow; the sub-sulphides white or yellow; and the per-sulphides red.

The examples which lead to this generalization are as follows:—

K_4O blue grey, K_2O white, K_2O_4 chrome yellow.
K_2S reddish yellow, K_2S_2 orange, K_2S_5 liver brown.
K_2Cl blue, KCl white, Na and Rb chlorides the same.
Na_4O blue, Na_2O yellowish white, Na_2O_2 orange.
Cs_4O blue, Cs_2O white.
$(H_4N)_2S_2$ yellow, $(H_4N)_2S_5$ orange yellow.
CeO white, Ce_2O_3 fawn red.
U_3O_4 green, U_2O_3 brick red.
$FeCl_2$ white, $FeCl_3$ brown.
Cr_2O_3 green, CrO_2 yellow green, CrO_3 red.
MnO olive, Mn_3O_4 red brown, Mn_2O_3 brown black.
MnS dark green, MnS_2 brown red.
SnO olive brown, SnO_2 yellow.
SnS blue grey, SnS_2 yellow.
MoO purple brown, MoO_2 dark brown.
MoS_2 lead grey, MoS_3 dark brown.
$MoCl_2$ deep blue, $MoCl_4$ dark red.
W_2O_5 blue, WO_3 yellow.
Sb_2O_3 grey white, Sb_2O_5 pale yellow.
Sb_2S_3 blue black, Sb_2S_5 orange yellow.
Bi_2O_3 yellow, Bi_2O_5 brown.
Cu_2Cl_2 white, $CuCl_2$ liver colour.
PbO yellow, Pb_3O_4 red, PbO_2 brown.
PbS lead grey, PbS_2 red.
Tl_2O yellow, Tl_2O_3 brown.
HgI green, HgI_2 yellow or red.
Au_2O dark green, Au_2O_3 brown.
$PtCl_2$ olive, $PtCl_4$ orange.
$OsCl_2$ green, $OsCl_4$ red.

With fuller information on the rare and unstable compounds, than is to be found in ordinary text books (such as "Miller's Elements"), no doubt numerous other instances might be noticed; these, however, will suffice to exemplify the general law.

With regard to black compounds, I have not included them in the above list, as they only complicate it unnecessarily; the ordinary term *black* being used to describe a very minute amount of any possible colour. It is only when the predominating colour is observed (as blue- olive- red-black, &c.), that the description is of any value. "Brown" is likewise ill-defined in its spectral position, as various tints called brown generally include a small quantity of any colour except blue. Black and brown compounds are therefore inconclusive without a spectral examination of the colour in each case.

The real anomalies to the above law are the following compounds. $CrCl_2$ white, Cr_2Cl_6 violet; $MnCl_2$ pale pink, $MnCl_3$ green brown; As_2S_2 red, As_2S_3 yellow; HgCl yellow white, $HgCl_2$ white; AuI yellow, AuI_3 green. In these five pairs the law is apparently reversed, but they cannot be said to nullify an induction from thirty-five pairs, as enumerated above. A conformity of six cases in seven to a rule is sufficient to establish it as a law, from which the modifying causes have not yet been eliminated.

One or two other cases might at first seem to be also exceptions; but as they are really *salts*, in which the electro-positive of the base is the same element as that of the acid, they are not necessarily to be compared with binary compounds.

In the order of the colours, it will be observed that, in numerous cases, white occurs between blue and yellow compounds; and there is only one instance of a violet compound with more of the electro-negative element than its white connection. As white light comes (in the natural arrangement) between blue and yellow, this order is more in accordance with the spectrum than is the order of metachromism announced by Mr. Ackroyd, in which white occurs before violet.

It may be worth notice that the electro-negative elements (whose increase reddens the compounds) are, on the whole, rather more red and yellow than the electro-positive, many of which are bluish, and even dark blue, as Na.

This order of colours in successive compounds of a series (which might be called taxichromism) was observed by the writer some few years ago, in connection with the spectral order in metachromism; the latter, however, was only traced through a dozen or so, of the oxides, without pursuing the subject farther.

Bromley, Kent W. M. FLINDERS PETRIE

Seasonal Order of Colour in Flowers

I THINK it may be useful to mention, in reference to several letters on this subject in NATURE, that light appears to have no direct influence on the tints of flowers. I quote the following from Sachs's Textbook, Engl. transl., p. 675:—

"As long as sufficient quantities of assimilated material have been previously accumulated, or are produced by green leaves exposed to the light, flowers are developed even in continuous deep darkness which are of normal size, form, and colour, with perfect pollen and fertile ovules, ripening their fruits and producing seeds capable of germination."

W. T. THISELTON DYER

Rainbow Projected on Blue Sky

AN instance of this phenomenon, which is referred to as rare in NATURE (vol. vii. p. 68), occurred to-day, Feb. 22, 4.30 P.M. The sky was almost quite clear and a light shower of rain falling, caused one to look upwards for the clouds whence it proceeded, but the air was uniformly clear near the zenith, though bordering the horizon all round there were some detached cumuli, and a few thin filmy modifications higher in N.E. There were no visible signs of the origin of the falling drops. On turning round to east, a solar bow was seen, for the most part on a background of azure. It was a *complete* bow and moderately intense. Near the vertex it rested on thin clouds, as did the extremities on the horizon, but they had no sensible effect on the phenomenon, for it was observed that as they receded from the upper portion, the bow remained intact and equally bright in all its parts. The arms spanned areas of blue sky. It was very transient, like the shower, and fading rapidly, was gone within 10 sec. after it was first observed. At 4.45 P.M., the left side of an incomplete bow was seen in N.E. on clear sky, except at the lower extremity: no rain accompanied it. It was as evanescent as the first. The weather was very unsettled and showery with low barometer. Thermometer 50°, with brisk wind from W.S.W.—3½ inches of rain had fallen during the previous 9 days.

WILLIAM F. DENNING

Ashleydown, Bristol, Feb. 22

OUR ASTRONOMICAL COLUMN

OLBERS' COMET OF 1815.—The comet discovered by Olbers, at Bremen, on March 6, 1815, and with which his name has been usually associated, belongs to the group, the members of which revolve in periods a few years less than the period of the planet Uranus. The deviation from parabolic motion was remarked independently a few months after the discovery by Bessel, Gauss, Olbers, Nicolai, and Triesnecker. Bessel calculated elliptic elements so early as the middle of May, and was followed by Gauss in June, and the former subsequently investigated, as completely as was practicable at the time, the elements resulting from the whole course of observation and the effect of perturbation in the actual revolution.

When first detected, the comet is said to have been barely visible in a good achromatic, and according to the *Zeitschrift für Astronomie*, was not discernible without telescopic aid at any time; it is, however, upon record that in Russia it was seen with the naked eye. The last observation was made by Gauss at Göttingen, on August 25. At discovery on March 6, at 10 P.M., it was in R.A. 49°·3 and N.P.D. 61°·3, distant from the sun 1·47 and from the earth 1·30, and at Gauss's final observation it was in R.A. 217°·1, N.P.D. 84°·5, distant from the sun 2·10, and from the earth 2·36. Representing the intensity of light at discovery (calculated according to the usual expression $\frac{1}{r^2 \Delta^2}$) by *unity*, a maximum of 1·4 was attained on May 3, and it had diminished on August 25 to 0·16, or one-sixth of that at discovery.

Bessel's determination of the elements of this comet and of the perturbations to the next return will be found in *Abhandl. der Berl. Acad. Mathem. Cl.* 1812–15. His definitive figures are as follow:—

Perihelion Passage, 1815, April 25·99867 M.T. at Paris.

Longitude of the perihelion	149° 1′ 56″
" " ascending node	83° 28′ 34″
Inclination to ecliptic	44° 29′ 55″
Excentricity	0·9312197
Semi-axis major	17·63383

These elements apply to the date of perihelion passage; the longitudes from mean equinox of 1815.

To the above value of the semi-axis corresponds a period of revolution of 74·049 years. The distance in perihelion is 1·213 (the earth's mean distance from the sun being taken as *unity*), and the aphelion distance 34·055; the minor semi-axis is found to be 6·427. The ascending node is situate near the orbit of the planet Mars, and if the actual form of orbit is due to planetary attraction, it is probably to be ascribed to a near approach of the comet to Mars at some distant period. At the other node the radius-vector is 3·81 in the region of the minor planets. The comet, it will be seen, recedes beyond the orbit of Neptune, but near the aphelion it has a depression of nearly 40° below the plane of the ecliptic.

According to Bessel, the mean motion at the instant of perihelion passage in 1815 corresponded to a period of revolution of 27046·9 days, and he found that this would be diminished 824·5 days by the united action of the planets Jupiter, Saturn, and Uranus, thus obtaining 26222·4 days for the actual revolution, and fixing the next arrival at perihelion to 1887, February 9·4. Beyond doubt, however, this date may now admit of a closer determination, and very probably we may soon hear of a further investigation being undertaken. The original observations made at the Observatory of Paris, and those at one or two other observatories in greater or less detail, are

in our possession, and will admit of more accurate reduction than has yet been effected; while a more complete computation of the perturbations with the improved values for the masses of the disturbing planets must tend to diminish the uncertainty that at present exists with regard to the possible error of Bessel's determination of the date of next passage through perihelion. If this should fall about 1887, February 9, as he computed, we might expect that the comet would be detected in September previous in the constellation Monoceros; its intensity of light would gradually increase until its nearest approach to the earth (0·5) at the end of the year, when it might be a conspicuous naked eye object in Ursa Major, within 20° N.P.D., and possibly it would be observable till the following May. Subjoined are figures which will enable any reader who is interested in the matter to trace the comet's course more precisely, upon the above supposition as to perihelion passage.

MINOR PLANET, No. 160.—A telegram to the Astronomer Royal, through the Smithsonian Institution, notifies the discovery of another small planet on February 25, in R.A. 10h. 16m. N.P.D. 75° 28′; eleventh magnitude.

THE BINARY STAR ω LEONIS.—Dr. Doberck, of Col. Cooper's Observatory, Markree Castle, Sligo, publishes in *Ast. Nach.*, No. 2,078, provisional elements of this interesting star, viz., peri-astron passage, 1842·77; node, 151° 34′; node to peri-astron on the orbit, 122° 54′; inclination, 65° 22′; excentricity, 0·5028; period of revolution, 107·62 years.

SCIENCE AND ART IN IRELAND

IN our number for February 17, we reprinted from the *Times* an article on the proposed action of the Government in connection with the Scientific Institutions in Dublin. That article contained the substance of Lord Sandon's letter which was forwarded both to his Grace the President of the Royal Dublin Society and to the President of the Royal Irish Academy. This letter was laid before the Irish Academy at their meeting of the 14th Feb., and was by them referred to the Council of the Academy. This latter body having in several meetings fully considered the whole subject, submitted to the Academy on Monday evening, the 28th Feb., the following Resolutions:—

"1. That the Royal Irish Academy is desirous of cooperating with Her Majesty's Government in the measures necessary for the establishment of a National Science and Art Museum in Dublin, provided that the independence and usefulness of the Academy be not injuriously affected by such measures.

"2. That, while we consent to the transfer of our Museum to the Government, we think that its arrangement, as well as the purchase of additions, should be done through the Academy.

"3. That, in thus assenting to the transfer of its Museum to the Government, the Academy also thinks that adequate provision should be made for the continued acquisition of Irish Antiquities, which may hereafter be discovered or offered for sale; and that the collection of the Academy, together with such other Irish antiquities as shall be added to it, should be for ever kept apart from Miscellaneous Art collections in the possession of the Government, and be permanently maintained as a Museum of our National Antiquities, no portion of its contents being ever removed from the City of Dublin.

"4. That, considering the position which the Academy has long held, and will continue to hold, as the first Scientific, Literary, and Antiquarian Society of the country, the proportional representation proposed to be given to it on the Board of Visitors (sect. 12 of Lord Sandon's letter), is altogether inadequate; and the Academy further think that no paid official of the Science and Art Department should be eligible to act as a representative on the Board.

"5. That, as the Academy is making a substantial concession in respect to its Museum, there should be provided in the yearly estimates, as laid before Parliament, instead of the several sums now annually voted, a sum of 2,000*l.*, to enable the Academy to discharge more completely its functions as a Scientific, Literary, and Antiquarian body, by making grants in aid of original research, by publishing the results of such research, by maintaining a library specially adapted to assist learned investigation, and by editing and printing ancient Irish Texts.

"6. That the Academy should be accountable, as at present, to her Majesty's Treasury, through the Irish Government, for the sum to be thus voted by Parliament, and should not be subject, in the conduct of its affairs, or the expenditure of its grants, to any control on the part of the Science and Art Department, or any of its officers."

After some discussion the Academy adjourned to the 6th of March, when it is probable that the resolutions of the Council may be adopted by the Academy, and a deputation appointed to confer with her Majesty's Government on the subject.

The Council of the Royal Dublin Society have also, we understand, drawn up a report with resolutions, to be submitted to a special meeting of the Society which is to be held to-morrow.

We hope in our next number to be able to report the resolutions come to by both bodies, and in the meanwhile refrain from making any comments on the subject.

THE LOAN EXHIBITION OF SCIENTIFIC APPARATUS

A MEETING of the General Committee for this approaching Exhibition was held on Thursday last at the Science Schools, South Kensington Museum. The chair was taken by the Lord-President of the Council, the Duke of Richmond and Gordon, the Vice-President, Lord Sandon, M.P., sitting at his side. Many well-known representatives of science were present.

The Lord-President spoke as follows:—

"It gives me very great pleasure to meet you at the expiration of some twelve months since we first assembled to set in motion a plan for holding a scientific exhibition, and I am happy to be able to congratulate you upon the success which has attended your efforts. The exhibition promises to be the most brilliant one of the kind that has ever taken place in this country. Indeed, I doubt very much whether there has ever been any exhibition in England at all approaching in importance or merit the one which is to be held within the next few months; and I cannot refrain from tendering the thanks of her Majesty's Government to those gentlemen who by their exertions in bringing about this exhibition have contributed so much to the success which we hope will follow. We appreciate the efforts of those gentlemen the more because we know that, engaged as they are in various scientific pursuits, the time which they have devoted to this matter must have caused them considerable inconvenience, and only their love of science could have induced them to render the services which they have done for the carrying out of the object. It is also gratifying to find that this exhibition has met with such a large amount of favour in all parts of the Continent, and more especially

in Germany, where the Crown Princess seems to have evinced in this case her great interest in the country from which she came, and I believe it is mainly owing to her exertions and those of the Royal Family in that country that so far as Germany is concerned we are to be so ably assisted. It may not be uninteresting to the meeting that I should describe in a very few words what has been done in the present state of matters with regard to the exhibition. At meetings of the various sub-committees (appointed at the General Committee meeting in June last) during the months of February and November, reports were made of the results of visits to foreign countries by officers of the department. The sub-committees made various suggestions to the department as to objects to be procured. These have been acted upon, and many most interesting objects obtained. The committee also advised that gentlemen should be employed to visit various towns and leading manufacturers. This has been carried out with the best results by Prof. Shelley, Mr. Akroyd, Dr. Martin, Prof. Morris, Mr. Judd, and Mr. Norman Lockyer. The Foreign Secretary having through her Majesty's Ministers abroad urged the importance of co-operation on the part of foreign Governments, our appeal has been most cordially responded to. The Governments of Belgium, France, Germany, Holland, Italy, and Switzerland, have appointed committees to act in union with the general committee; and the Government of the United States has placed itself in communication with the various institutions and Government departments. Russia intends to contribute an interesting collection from the Pædagogical Museum; and the Russian Academy have formed a committee under Prof. Struve. The Austrian Minister of Instruction has taken the matter in hand for that country, and one of his officers, Mr. Fidler, is in correspondence with the Science and Art Department. I mention this to show you the intense interest that foreign countries have taken in the matter, and that to their assistance and co-operation we feel very much indebted. The appeals made to Government departments, scientific institutions, and men of science at home have been very well received. The Admiralty contributes a complete scientific outfit of a surveying ship, dredging apparatus, &c. The Post Office contributes as complete a historical collection of telegraphic apparatus as exists; much, however, unfortunately, has been broken up for want of a physical museum in which to deposit it. They also propose to communicate Greenwich time, and fire a time gun, to illustrate their method of communicating time throughout the country. The Trinity House, Ordnance Survey, Royal Observatory, and Geological Survey have also promised to contribute. From the War Office and India Office no replies have been received, but we understand they are taking steps to contribute several objects of interest, especially from the Royal Arsenal at Woolwich. The Royal Society contributes a most important collection, including some of Newton's apparatus. The Royal Institution contributes historical apparatus used by Faraday and others, and some of Dr. Tyndall's instruments. The Astronomical Society contributes Baily's apparatus for the Cavendish experiments, and Sir W. Herschel's telescope. The Geographical Society contributes maps and instruments. The Microscopical Society has promised to organise a collection of microscopes, which Mr. Sorby has especially in charge; the Horological Institute a collection of clock escapements, &c., and the Royal College of Surgeons has promised an interesting collection. King's College has promised to contribute the collection of the late Sir C. Wheatstone. At Owens College, Manchester, Professors Roscoe, Stewart, Schorlemmer, and Reynolds have promised to contribute valuable apparatus, as have also Professors Tait and Crum Brown at Edinburgh, and Sir W. Thomson at Glasgow. Trinity College, Dublin, has also promised to contribute. Contributions have been promised by the following noblemen and gentlemen, viz.:—Dr. Joule, Prof. Andrews, Mr. Gore, Lord Rosse, Mr. De la Rue, Lord Cork, Dr. Frankland, Prof. Guthrie, Mr. Norman Lockyer, Dr. Ball, Prof. O'Reilly, Prof. Barrett, and Prof. Stokes. Among instrument makers who will contribute specimens of their apparatus may be mentioned Messrs. Elliott, Apps, Browning, Adie, Grubb, Cooke, and Tisley. The following map makers will contribute:—Messrs. Stanford, Murby, and Keith Johnston. Numerous collections for teaching have been promised. Among these may be mentioned an exceedingly interesting collection prepared by Prof. Guthrie. All this apparatus is made out of simple materials by the students themselves. A committee, consisting of Dr. Stone, Dr. Pole, Mr. W. Chappell, and Mr. Baillie-Hamilton, are forming a most interesting collection illustrative of the scientific principles on which the construction of musical instruments is based. Mr. Markham is forming a collection of Arctic maps, Mr. F. Galton a collection of exploratory apparatus, Mr. Scott a collection of meteorological apparatus, and Dr. Mann a collection of instruments connected with atmospheric electricity. Various local committees have been formed to forward the objects of the Exhibition. Amongst them may be mentioned one at Leeds for Yorkshire, arising from the exertions of Prof. Thorpe. Among other interesting objects from Germany, we may look for some of Tycho Brahe's instruments, and the original air-pump of Otto von Guericke. From France we have as yet no very definite information, but we expect a very interesting collection, as the French Commission, consisting of members of the Academy of Sciences, have devoted considerable attention to the Exhibition, and the Conservatoire des Arts et Métiers have promised some of their finest things. From Italy it is hoped that some of the instruments used by Galileo, Torricelli, Volta, and Galvani may be obtained. In consequence of want of room in the South Kensington Museum, it is intended to hold the Exhibition in the western galleries of the buildings lately used for the Annual International Exhibitions, her Majesty's Commissioners having most obligingly placed them at our disposal for the purpose. I cannot overrate the advantages we have derived from the services of Mr. Norman Lockyer, who has been transferred temporarily to this department. Professors Guthrie and Goodeve have also assisted us most remarkably, and various learned societies have been invited to organise conferences and conversazioni." His Grace concluded by suggesting the desirableness of forming one or two sub-committees for the purpose of making the necessary arrangements for the reading of papers, conferences, and receptions, and expressing his confidence that a cordial welcome will be accorded to distinguished scientific visitors from other countries.

Dr. Hooker moved "that a sub-committee be formed, consisting of the presidents and one vice-president of each of the learned societies, to consider the reading of papers, conferences, and demonstrations; and, secondly, the arrangements for the receptions." Mr. Warren De la Rue seconded the motion, which was carried.

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA[1]

III.

ORDER *Proboscidea*.—This name has been appropriated to a well-marked group of animals, presenting some very anomalous characters, allied in many respects to the Ungulata, but belonging neither to the

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.) Continued from p. 308.

Artiodactyle nor Perissodactyle type of that order. It has been thought that they possess some, though certainly not very close, affinities with the Rodentia, and also with the Sirenia. It is certain, however, that the two species of Elephant which are the sole living representatives of the order, stand quite alone among existing mammals, widely differing from all others in many parts of their structure, being in some respects, as in the skull, dentition and proboscis, highly specialised, though in others, as in the presence of two anterior venæ cavæ and in the structure of the limbs, retaining a low or generalised condition. A considerable series of extinct forms, extending back through the Pliocene and Miocene epochs, show the same type under still more generalised outlines. Though no true Proboscidians have as yet been found in any Eocene formations, certain recently discovered forms of that epoch from North America, if their affinities are rightly interpreted, may link them to some unknown primitive type of Perissodactyle Ungulate. The consideration of these will, however, be reserved until the next lecture.

All the true *Proboscidea* are arranged in three principal groups or genera—*Elephas*, *Mastodon*, and *Dinotherium*. Their molar teeth, by which the extinct species are chiefly known, present a remarkable series of modifications, from the comparatively simple tapiroid teeth of *Dinotherium*, with two or three strongly pronounced transverse ridges, and a normal mode of succession, to the extremely complex structure and anomalous mode of replacement found in the true Elephants. The intermediate conditions occur in the various species of Mastodon. In this genus the enamel-covered transverse ridges of each tooth are generally more numerous than in *Dinotherium*, and often complicated by notches, or by accessory columns attached to them, but in the unworn tooth they stand out freely from the crown, with deep valleys between. In the Elephants the ridges are still further increased in number, and are greatly extended in vertical height, so that, in order to give solidity to what would otherwise be a laminated or pectinated tooth, it becomes necessary to envelop and unite the whole with a large mass of cementum, which completely fills up the valleys, and gives a general smooth appearance to the organ when unworn; but as the wear consequent upon the masticating process proceeds, the alternate layers of tissue of different hardness, cement, dentine, and enamel, which are disclosed on the surface, form a fine and very efficient triturating instrument. The modification of the tooth of a Mastodon into that of an elephant is therefore precisely the same in kind as that of the molar of a Palæotherium into that of a horse, or of the corresponding tooth of an early Artiodactyle into that of an ox. The intermediate stages, moreover, even as our knowledge already extends, are so numerous that it is not possible to draw a definite line between the two types of tooth structure. As regards the mode of succession, that of the modern elephants is, as before mentioned, very peculiar. During the complete lifetime of the animal there are but six molar teeth on each side of each jaw, with occasionally a rudimentary one in front, completing the typical number of seven. The last three represent the true molars of the ordinary mammals, those in front appear to be milk molars, which are never replaced by permanent successors, but the whole series gradually moves forwards in the jaw, and the teeth become worn away, and their remnants cast out in front, while development of others proceeds behind. The individual teeth are so large and the processes of growth and destruction take place so slowly, that not more than one, or portions of two teeth, are ever in place and in use in each side of each jaw at one time. On the other hand the Dinotherium, the opposite extreme of the Proboscidian series, has the whole of the molar teeth in place and use at one time, the milk molars having been vertically displaced by pre-molars in the ordinary fashion. Among Mastodons transitional forms occur in the mode of succession as well as in structure, many species showing a partial vertical displacement of the milk molars, and the same has been observed in one extinct species of Elephant (*E. planifrons*).

Abundant remains of fossil elephants have been found in Pleistocene and Pliocene deposits in many parts of Europe, including the British Isles, in North Africa, throughout the North American continent from Alaska to Mexico, and extensively distributed in Asia. These species are chiefly known and characterised at present by the teeth, some of which resemble the existing Indian, and some the African type, but the majority are intermediate between the two, and make the distinction between *Elephas* and *Loxodon* as different genera quite impracticable. Others, again, approach so closely in breadth and coarseness of the ridges, and paucity of cementium to the Mastodons, as to have been placed by some naturalists in that genus. These form the group or sub-genus called *Stegodon* by Falconer. The best known extinct species of elephant are *E. primigenius*, the Mammoth, very closely resembling the existing Indian Elephant, of Pleistocene age, extensively distributed throughout Northern and Central Europe, North Asia, and North America, though most of the remains attributed to it in the latter country may belong to another species, *E. Americanus*, De Kay, which, according to Leidy, includes *E. Columbi*, Falc. In the frozen soil of North Siberia, complete animals, with the flesh and hair upon them, are often found, and their tusks are still collected in large quantities and in a sufficiently perfect condition to be used as ivory. *E. antiquus* and *E. meridionalis* are two other species found in Britain as well as Europe generally, of rather earlier date, and inclining more to the *Loxodon* type, as also do two species found in the island of Malta, *E. mnaidriensis* and *E. melitensis*, the latter the smallest known species of the group, sometimes not exceeding three feet in height when adult. The *Stegodon* forms, *E. clifti*, *bombifrons*, and *insignis* of Falconer and Cautley, are all from India, which would appear, from the abundance of remains, variety of form, as well as the generalised characters of some, and the geological horizon (Lower Pliocene) to be the earliest habitation of the true elephant yet discovered.

The Mastodons are distinguished from the elephants principally by the form of the molar teeth; the only absolutely distinguishing character, and that somewhat of an arbitrary one, being that the third, fourth, and fifth molars have an equal number of ridges, whereas in the elephants the third and fourth are alike, but the fifth has a larger number. In addition to the great incisor tusks of the upper jaw they often, but not invariably, have lower incisors, which are always wanting in the elephants. They are all gigantic animals, equalling or exceeding the recent elephants in size. Their remains have been found in Europe and Southern Asia in Miocene and Pliocene beds, but not of an earlier or later date. Two species, *M. arvernensis* and *M. borsoni*, occur in England in the Suffolk Red Crag. They have also been found in both South and North America. In the latter, *M. Americanus*, Cuv., *M. ohioticus*, Blumenb., with very simple ridged molars, is of Pleistocene age, its remains being found in great abundance and very perfect condition. It was, therefore, the last survivor of the genus. The Mastodons were divided by Falconer into three series called respectively *Trilophodon*, *Tetralophodon*, and *Pentalophodon*, according to the number of ridges upon the molar teeth.

The *Dinotheria* were also animals of elephantine proportions, strikingly characterised by the pair of huge tusks descending nearly vertically from the fore part of the lower jaw. The presence or absence of upper incisors has not yet been satisfactorily ascertained. The cranium was much depressed, differing from that of the elephants in the comparatively little development of the air-cells,

The remainder of the skeleton is imperfectly known, but apparently agrees in its general characters with the other Proboscideans. Its remains have been met with in abundance at Eppelsheim, near Darmstadt, and also in various other Miocene formations in the South of Germany, France, and Greece; in Asia Minor, Attock in the Punjab and Perim Island, but whether all belonging to one species (*D. giganteum*, Kaup.) or to several, the materials are not at present sufficient to determine. The genus has not hitherto been found in England or in America.

The gradual transition in the character of the molar teeth of various Proboscideans is well illustrated by the following table (compiled from Dr. Falconer's Memoirs) of the "ridge formula" of various species. The numbers are, however, only averages, and it must be remarked that the higher the numerical expression of the ridge formula in the species the more liable is the number of ridges to vary within certain limits, especially in the teeth of the lower jaw, where they are often in excess. Several species, apparently intermediate in ridge formula to those in the table, have since been discovered, as *Mastodon pentelici* and *andium*, which break down the distinction between the sections *Trilophodon* and *Tetralophodon*, and *Elephas melitensis* between *Loxodon* and *Euelephas*.

(*To be continued.*)

THE FIRST GENERAL GEOLOGICAL MAP OF AUSTRALIA [1]

FROM its vast size and its peculiar conditions of physical geography the island-continent of Australia presents formidable difficulties alike to the topographical and the geological surveyor. Of its wide desert interior we know nothing more than what has been seen or conjectured along the tracks of the few adventurous men who have penetrated it. The eastern and southern colonies have been more or less thoroughly geologised, and expeditions have been sent to make known the capabilities of portions of the western and northern coasts. Several of the colonies have equipped geological surveys, though they have not always cared to maintain them. A great deal of miscellaneous knowledge regarding the rocks of the country has thus been acquired, but it is scattered through hundreds of blue-books, reports, memoirs, transactions of societies, newspapers, and other publications. Those who are most familiar with Australian geology, can best judge whether the time has now come when this store of diffused information may be profitably condensed in the form of a general map of the whole country. Mr. Brough Smyth has deemed that it may, and accordingly he has produced the present map—the first general geological map of Australia which, so far as we are aware, has been published.

No one could have performed so well as Mr. Smyth the difficult task of compiling this map. From his official position as Secretary for Mines in Victoria, he has, of course, unequalled facilities for doing justice to his own Colony; and from correspondence with the government departments of the other colonies, he has obtained access to all the stores of information which successive surveys and expeditions have brought into the archives of the different governments. In the winter of 1872-3 he obtained the consent of his own government to his plan for elaborating a general map of Australia, and he immediately set to work to solicit information from all quarters. In his Progress Report, dated Oct. 1, 1873, he acknowledged the assistance already received from Queensland, Western Australia, South Australia, and Tasmania, but regretted the existence of many blanks, instancing in particular the want of a geological map of the important colony of New South Wales. The present map, however, bears the conspicuous date of April 25, 1873, though confessedly incomplete in October of that year, and not published until November 1875. Mr. Smyth's name alone appears on the title. No doubt he will take care to state fully in the text which it is proposed to issue in illustration of the map, the share which others have had in the real geological surveying of which he has so carefully gathered the fruit. Still, when we think of the many years of hard bodily and mental toil which such men as W. B. Clarke, Selwyn, Daintree, and others have given to the working out of Australian geology, we cannot help expressing a feeling of disappointment that on the fore-front of this first geological map of the country no place should have been found for their names.

With the exception of this omission, which may have arisen from inadvertence, and may yet be fully atoned for, little but the most unqualified praise is to be given to this map. We have already had occasion to call attention in this journal to Mr. Brough Smyth's great energy, and to the important services which he is rendering, not only to the industrial development of Victoria, but to the progress of geology. He has probably never accomplished, however, any task more likely to be of service in Australia or more useful to geologists in other countries than this first sketch of a geological map of that great region. Though the scale of the map is only $\frac{1}{7000000}$ or 110 miles to an inch, it is no doubt quite large enough for a beginning. It shows the salient features of the geology without too many confusing details. As a specimen of cartography, the map is one of the best which has recently appeared, and it does great credit to the taste and skill of the engravers and lithographers of the Mining Department at Melbourne, where it has been produced.

The first point about this map which will probably occur to most geologists is the comparatively large area over which it has been found possible to spread geological colours. The surveys and explorations of Queensland, New South Wales, Victoria, Southern and Western Australia, have sufficed to furnish materials for colouring most of the maritime tracts, as well as a large part of the eastern half of the continent. But it might have been supposed that in spite of the journals of the few adventurers who have crossed the interior, that great inland desert would have been left an uncoloured blank upon the map. Mr. Smyth, however, has made the most of every scattered notice and stray observation. He has, coloured the exploring tracks across the country in such a way as to suggest very clearly what must be the geological structure of the interior. The eastern mountain-chain bringing up the crystalline and older palæozoic rocks from Bass Strait to Torres Strait is well shown. On the western coast an enormous mass of granite is marked as stretching over fifteen degrees of latitude, and spreading far into the interior, where it seems to pass under the vast sheets of "desert sandstone," which occupy so much of the low interior of Australia. Carboniferous rocks are coloured over large spaces in Eastern Queensland, but the compiler of this map stops the tint

[1] First sketch of a geological map of Australia, including Tasmania. By R. Brough Smyth, F.G.S., &c.

short at the northern limits of New South Wales, and makes the coal-field of that colony Mesozoic, against the earnest protest of the Rev. W. B. Clarke, whose judgment on all matters concerning the geology of New South Wales is not to be lightly opposed. Cretaceous strata, first recognised from fossil evidence by Prof. M'Coy, are represented as covering a wide belt of country from the plains south of the Darling northwards to the Gulf of Carpentaria. The tertiary deposits are massed under one tint, which spreads over most of the interior, sweeping up to the base of the inland slopes of the Eastern Alps, and down to the coast-line for many leagues on the northern, western, and southern margins of the country.

No arrows to show prevalent inclinations of strata have been inserted on the map, and as no illustrative sections are given, the reader is left to infer the relations of the formations whose general area and boundaries are so clearly defined. The required information may be expected in the promised text to accompany the map. Another omission is the want of any sign for the gold and coal-fields. This might have been easily inserted without any diminution of the clearness and beauty of the map, and would have been of value to those who take interest in the mineral resources of the country. It is to be hoped that a new edition will soon be demanded, and that these small defects in a most useful and meritorious work will be supplied.

PHYSICAL SCIENCE IN SCHOOLS

We have received the following additional letters on this subject:—

Your Rugby correspondents appear to me somewhat to misapprehend Dr. N. M. Watts's arguments on this important question. No satisfactory results, he maintains, can accrue from science teaching in schools until the subject is placed upon its true position of *educational equality*, both as regards range and time, with classics and mathematics, and no system of regulations or of examinations can be said to fulfil its object in which this position is ignored. I for my own part most cordially support Dr. Watts's views. The position at present accorded to science in English schools is, as Sir John Lubbock has clearly shown, anything but satisfactory, and this state of things seems likely to continue so long as the examinations for which the boys prepare persist in placing the science subjects in a distinctly inferior position to the older studies. Surely it is the part of examining bodies to lead and raise the education of the country. I think, however, that it has been fully proved that the "Oxford and Cambridge Schools Examination Board" has not done this, at any rate so far as science is concerned. The facts adduced by Mr. Cumming as to the small number of candidates presenting themselves for examination in science proves to my mind that the teaching of science is usually discouraged because it is usually not understood, and no efficient means of teaching science being as a rule provided, these subjects are not only neglected but their study becomes even despised by the boys. The truth is that it is the difficulty of obtaining such men as Mr. Wilson and Dr. Watts which renders the progress of science teaching in schools less rapid than some of us could wish. As soon as the supply of really competent and high class natural science masters becomes as large as that of equally distinguished teachers of classics or mathematics we may be sure that science will occupy no inferior position. Until that time arrives it behoves all those interested in the educational applications of science to take care that the teaching is really exact, methodical, and disciplinary, in short, scientific, so that if we do not progress rapidly we advance all the more surely, and we look with interest to the results of the education in those few schools such as Giggleswick and Newcastle-under-Lyne, in which science has already been placed on a footing of equality with the older studies.

Manchester, Feb. 26 HENRY E. ROSCOE

The remarks of Dr. Marshall Watts on physical science in schools in NATURE (vol. xiii., p. 311), seem to me to call for one or two observations in addition to those made by Mr. Wilson and Mr. Cumming in your columns last week (p. 329).

Dr. Watts selects a few questions from the examination papers that were set in heat, chemistry, and geology, by the Oxford and Cambridge Schools Examination Board in 1854, the first year of its existence, in order to show what he considers the very elementary nature of the knowledge required, and he adds that "with the exception of the last question [naming certain rocks and fossils] there is no test of a practical kind at all."

Now it is only fair to state that although it is quite true that there was no examination in practical chemistry in 1854, yet in the regulations for the next year "the elements of practical qualitative analysis" were added to "the elementary parts of inorganic chemistry," and last July those candidates who took in chemistry were examined for three hours in practical laboratory work, six substances being given to each boy for analysis.

Moreover, with regard to theoretical chemistry, the paper that was set last year was decidedly harder than that of the year before. I inclose a copy, and should be glad if you could find space to print it. As a matter of fact it is harder than the average chemistry papers of the London University Matriculation Examination, and quite as hard as an ordinary Oxford Pass Paper.

"*Natural Philosophy* (*Chemical Division.*) (*Time* $1\frac{1}{2}$ *hours.*)

A.

"1. What happens when pure iron is dissolved in excess of dilute sulphuric acid? Give an account of the properties of the solution which is obtained, and the tests by which you would show what salt of iron is present. Suppose some of the solution were boiled with potassium nitrate, what changes would you expect to take place?

"2. Explain atom, molecule, acid, base. How can you show the composition by weight and volume of hydrogen with chlorine, bromine, and iodine? mention the best methods of obtaining these compounds in the state both of gas and in solution.

"3. How is analysis of air made with the eudiometer? Describe how to correct the observations for pressure, temperature, and aqueous vapour. Suppose 100 c.c. of oxygen to be mixed with 10 c.c. of marsh gas and exploded, find the amount of the residual gases.

"4. What is the percentage composition of nitrous and nitric oxides? How are these bodies prepared? Distinguish between the properties of nitrates and nitrites.

"5. Describe briefly the manufacture either of sulphuric acid or of bleaching powder.

"6. Account for the production of carbon mon-oxide in the blast furnace, and show what action it has in reducing the roasted iron-stone. What is the best method of preparing carbon mon-oxide: in what respects does it differ from the di-oxide?

"7. How is the metal aluminium prepared? Describe the manufacture of alum, and give a brief account of the properties of alumina.

"8. Describe the preparation and properties of the bodies $SnCl_4$, HgC_2N_2, PbO_2, $K_2Cr_2O_7$, HCN.

"*Practical Chemistry.* (*Time* 3 *hours.*)

"1. The substances marked 1, 2, 3, 4 are simple salts.

"2. The substances marked 5, 6 are elements.

"You are requested to find out what they are, and to write a full account of the methods you use."

Now at the risk of being accused of taking a low standard, I cannot help thinking that although some of these

questions may be called "very easy," yet there are others quite sufficiently difficult for the ordinary public schoolboy, who has a great many other things to work at besides natural science.

A boy must have read his chemistry thoughtfully, to say the least, who could answer the whole of Question 1 thoroughly. In Question 2 there is ample opportunity for showing a deeper knowledge than could be obtained by skimming over some "outlines of chemistry." So again the explanation and illustration of the peculiar oxidising and reducing properties of *nitrites*, in Question 4, and the description of the preparation and properties of the different bodies enumerated in Question 8, could, I maintain, only be given satisfactorily by boys who had acquired something more than a mere "modicum" of chemical knowledge.

It must also be borne in mind that in order to pass the Chemical Division of Group IV., a boy must take in, in addition to the chemistry of the metallic and non-metallic elements and practical analysis, either heat or magnetism and electricity.

Now although there may be reasons for combining together heat and chemistry, so long as it is understood that only the more elementary parts of heat will be required, yet it is certainly unreasonable to add on as an extra such a very comprehensive subject as that of magnetism and electricity, frictional and voltaic, including electro-magnetism.

Surely, to say the least, electrical science is quite as worthy of an independent existence as botany or geology, and I much doubt whether many would hesitate in admitting it to be much harder than either.

My own opinion is in favour of Mr. Wilson's suggestion—to divide Group IV. into Pass subjects and Honour subjects, requiring only an elementary knowledge of theoretical chemistry, and perhaps the simpler parts of heat for the one, while practical analysis with higher knowledge of heat, *or* electricity and magnetism, might be required from those who aimed at taking honours in science.

It is perhaps due to the school to say that we can hardly be supposed to be frightened at the prospect of these examinations. Last July three in the Sixth took in chemistry as a certificate subject: all passed and two obtained "distinction"—three being the total number who obtained such distinction out of the twenty-eight candidates who presented themselves for examination in this subject. T. N. HUTCHINSON

Rugby

In my letter last week, p. 329, I said that the papers set in science in the certificate examination *last year* were very easy. This was a slip. I was absent from England when they were set, and had never seen them. I had in my mind the papers of the year before.

The papers of last year were quite hard enough. It must be remembered that very many schools give only *two lessons a week* to science. JAMES M. WILSON

ANNIVERSARY ADDRESS OF THE PRESIDENT OF THE ROYAL GEOLOGICAL SOCIETY, JOHN EVANS, F.R.S.

MR. EVANS began by referring to the immense advances in geological science since 1825, when the Society received its charter, and pointed out that although there now existed a considerable body of professional or trained geologists, yet amateurs need not be discouraged from taking up the science which now embraces so wide a field that there is ample room for both. He then referred to the prosperity of the Society, to its publication, its medals, and other means for fostering the science, and to its valuable museum, an "interesting notice of which," he intimated, "appeared in NATURE, vol. xiii. p. 227." Mr. Evans then spoke of the present prospects of the science, of the bearing which recent discoveries in other branches of knowledge has upon it, and of the direction in which future discoveries are likely to be made. In this connection he referred to the recent researches in solar physics by means of spectrum analysis and solar photography, as having a close and intimate bearing on the early history of the earth, and which was discussed by Prof. Prestwich in his inaugural lecture at Oxford (NATURE, vol. xi. p. 290). He spoke also of the importance of spectrum analysis to the metallurgist, referring to the researches of Mr. W. C. Roberts in quantitative analyses of gold-copper alloys. Mr. Evans then spoke at some length of the important results already attained by the *Challenger* Expedition as to the nature of the sea-bottom. In speaking of the Arctic Expedition, from which geology hopes to gain much, he referred to the powerful evidence which exists in the fossil flora of Greenland and Spitzbergen, of the prevalence in the Arctic regions at one period of a distinctly warm climate.

Mr. Evans then went on to say:—The three points which it appears to me are most important to bear in mind with regard to the Arctic flora are:—1, That for vegetation such as has been described, there must, according to all analogy, have been a greater aggregate amount of summer heat supplied than is now due to such high latitudes; 2, that there must have been a far less degree of winter cold than is in any way compatible with the position on the globe; and 3, that in all probability the amount and distribution of light which at present prevail within the Arctic circle are not such as would suffice for the life of the trees.

Should the present Arctic expedition succeed in finding traces of what must be regarded as a temperate, if not indeed a subtropical fossil flora, like that of Greenland, and Spitzbergen, extending to latitudes still nearer the pole, it does appear to me that geologists will be compelled to accept as a fact that the position of the axis of rotation of our planet has not been permanent; and they will have to call upon astronomers to find some means of admitting what they now regard as impossible.

An astronomer and mathematician of no mean ability, the late Sir John W. Lubbock, in a paper communicated to this Society in 1848, has speculated upon this subject, which was in consequence discussed by the late Sir Henry Delabeche in his Presidential Address in 1849.

Sir John Lubbock remarked that the dictum of Laplace as to the impossibility of accounting for the changes which have taken place on the surface of the earth, and in the relative positions of land and water, by a change in the position of the axis of rotation, was founded upon the absence of two considerations, both of which appeared to him essential. These were—

1. The dislocation of strata by cooling,
2. The friction of the surface.

The latter consideration is apparently of but little importance; but with regard to the former, he pointed out how, if from any cause the axis of rotation did not coincide with the axis of figure, the pole of the axis of rotation would describe a spiral round the pole of the axis of figure until it finally became, as it is at present, identical with it. He considered it unlikely that originally the axis of rotation should have coincided exactly with the axis of figure, unless the whole globe were perfectly fluid; but added that we might go back to a time less remote, when the earth was in a semifluid state, and in consequence of the different degrees of fusibility of different substances, was partly solid, in irregular masses, and the two axes did not, in consequence, coincide. We might, he added, assume the original state of want of uniformity between them to have been at a period even more recent, when the earth consisted of land and water, and was suited for the support of animal life. He then proceeds to show how, if, after any length of time the solid spheroidal part of the earth moved about any new axis of rotation, the water would occupy a new position about a new equator, land would become sea, and sea land, &c.

He adds that if the axis of the earth would suffer a displacement by reason of the causes which produce the precession of the equinoxes, we should have another and more natural way of accounting for the existing phenomena; but this has been held to be impossible.

I am not at present going to question whether this holding is correct; but with regard to Sir J. W. Lubbock's reasoning as to the necessity of the axis of figure coinciding with that of rotation, it appears to me of the greatest importance; for if it hold good, any alteration in figure cannot but have some effect on the position of the axis of rotation. No doubt, if the whole globe, or even the solid portion of it, were a regular spheroid, with a large

equatorial protuberance, any modification on its surface would have to be on an enormous scale to produce any sensible effect upon its axis of revolution. But, after all, is the earth, strictly speaking, a spheroid?—and are not some of the arguments and dicta based upon its spheroidal character founded on a fallacy? For it does appear to me a fallacy to treat as one homogeneous spheroid, a body partly consisting of a mass of solid or quasi-solid matter of irregular form, and partly of a liquid mass in constant motion, irregularly distributed over a portion of its surface. No doubt the contour of the liquid portion is, according to established geometrical laws, almost that of a regular spheroid; but its distribution, except in the case of inland seas, can have but little to do with the regulation of the movement of the solid body on which it rests. It is true that Laplace has maintained that "whatever may be the law of the depth of the ocean, and whatever the figure of the spheroid which it covers, the phenomena of precession and nutation will be the same as if the ocean formed a solid mass with this spheroid;" but do the position of the axis of revolution and its permanence in one spot come under the same category as precession and nutation? It certainly appears to me that the position of the axis of revolution must mainly depend upon the form of the mineral portion of the globe, and be but in the slightest degree affected by the distribution of the ocean, the specific gravity of which is moreover only about one-fifth of that of the more solid portion.

With regard to the permanence of the axis of rotation, if it must of necessity coincide with the axis of figure, and if the figure of the mineral portion of the earth, in consequence of upheavals and depressions, of the wearing away of continents and the transportation of their constituents by mechanical or even chemical means, is being constantly changed, so as to acquire a new axis, then the axis of rotation must also as constantly be undergoing a change of position.

Let us now glance at some of the irregularities of form of the more solid part of the globe as at present existing. The difference between the polar and equatorial diameters of our globe has been calculated at about 26 miles, or about 13 miles in the radius; but at the equator itself, little more than one-fifth of the circumference of the globe is dry land, and nearly four-fifths are sea; and this sea is by no means shallow, as the soundings taken by the "Tuscarora," the "Challenger," and other exploring vessels will prove. Leaving those taken near land out of the calculation, I find that 48 soundings in the Pacific, between 15° and 30° north latitude, give an average depth of 2,634 fathoms, or 5,268 yards, that is to say, within a few yards of three miles. The South Pacific does not appear to have been so well explored; but across the Atlantic, in the equatorial regions between 10° N. and 10° S., I find that an average of 32 soundings gives a mean depth of 2,309 fathoms, or 4,618 yards, while, in one spot in lat. 15° S., Sir James Ross did not find the bottom with a line of 4,600 fathoms, or nearly 5¼ miles. In the Indian Ocean, within the same limits, 20 soundings give an average of 2,468 fathoms, or 4,936 yards, or more than 2¾ miles. Taking these soundings as fair representations of the depth of the sea in the neighbourhood of the equator, it appears that we may at once reduce the equatorial diameter of the more solid part of the globe by from 5½ to 6 miles over nearly four-fifths of its circumference; that is to say, we may reduce the usually accepted equatorial protuberance from about 13 miles to a little over 10. It is not within my province to inquire whether the fact of so large a portion of the equatorial protuberance being of so much less specific gravity than if it were composed of mineral matter, will in any way affect the established calculations with regard to the precession of the equinoxes and the nutation of the poles, or, what is of more importance to us, the inferences with regard to the crust of the earth which have been thence deduced.

But while so large a portion of the surface of the land is, in the equatorial regions, so much below the normal level, there are, especially in the northern hemisphere, large tracts of land which, like the great plateau of Tibet, are some thousands of feet above it. The average elevation of the whole of Asia has, indeed, been estimated at 377 yards, or nearly a quarter of a mile above the sea-level. The depth of the ocean in non-equatorial regions must no doubt be taken into account; but practically, the spheroidicity of the globe, on which the stability of the pole has been held to depend, may be regarded as, even at the present time, considerably less than is usually supposed. When, however, we come to think of the enormous elevations and depressions which some parts of the globe have undergone during geological time, it is by no means difficult to imagine conditions under which the general average, so to speak, of the surface, would approach much more nearly to the form of a sphere, and the globe would become much more sensitive of any disturbances of its equilibrium; but whether the globe is a sphere or a spheroid, it is hard to see why disturbances of its equilibrium should not affect the position of its axis of rotation.

Taking our globe with the distribution of land and water as at present existing, I should like to inquire of mathematicians what would be the theoretical result of such a slight modification, geologically speaking, as the following:—Assume an elevation to the extent, on an average, of 4,000 feet over the northern part of Africa, the centre of the elevation being, say, in 20° north latitude. Assume that this elevation forms only a portion of a belt around the whole globe, inclined to the equator at an angle of 20°, and having its most northerly point in the longitude of Greenwich, and cutting the equator at 90° of east and west longitude. Assume that along this belt the sea-bottom and what little land besides Africa it would traverse were raised 4,000 feet above its present level over a tract 20° in width. Assume further that the elevation of this belt was accompanied by corresponding depressions on either side of it, so as to leave the total volume of the mineral portion of the earth unaffected. Would not such a modification of form bring the axis of figure about 15° or 20° south of the present, and on the meridian of Greenwich, that is to say, midway between Greenland and Spitzbergen? and would not, eventually, the axis of rotation correspond in position with the axis of the figure?

If the answer to these questions is in the affirmative, then I think it must be conceded that even minor elevations within the tropics would produce effects corresponding to their magnitude; and also that it is unsafe to assume that the geographical position of the poles has been persistent throughout all geological time.

It is not the first time that I have insisted upon this point; for, some ten years ago, I pointed out another possible means of accounting for a change in the geographical position of the axis of the earth. My hypothesis was, however, founded on the assumption of the globe consisting of a comparatively thin crust, with an internal fluid nucleus over which the crust would slide when, from any geological cause, its equilibrium was disturbed. To this it has been objected [1]—1st, That there would be a tendency in the transfer of sediment from one part of the globe to another, and in the various elevations and depressions of land simultaneously, to balance each other; and 2nd, that the friction over the nucleus would be too great, and that, owing to the earth being a spheroid and not a perfect sphere, any motion of the crust would be attended by great resistance, and the bending and rending of its mass.

To these objections it may be replied that the effects of the transfer of sediment from one place to another, and of elevations and depressions of land going on at the same time, are just as likely to be doubled by the depressions taking place in the same hemisphere as the elevations, but on opposite sides of the pole, as they are to neutralise each other; and, 2ndly, that with a comparatively thin crust, the readjustment to a fresh position on a nucleus so slightly spheroidal as that supposed to exist in the earth, is not accompanied by any great change of form, or certainly not more than what the contorted rocks all over the world have undergone.

I am not, however, on the present occasion, going to attempt to prove that the assumption involved in my hypothesis is reasonable. How we are to account for all the vast oscillations of the earth's surface, which we find to have been going on ever since the earliest geological period up to the present day, on any assumption more reasonable, I will leave for others to determine. I have already called attention to the bearing which recent researches in solar physics have upon this subject, and I am content to leave the matter as it stands, in the hope that before many years have passed, we may learn more either in its proof or disproof.

The moral which I wish to draw from all that I have just said is this:—That so long as there is a possibility, not to say a probability, of the geographical position of the poles having changed, it is premature to invoke intense glacial periods to account for all the glacial phenomena which may be observed. Much as we must esteem the labours of M. Adhémar and Mr. Croll, and others who have gone so deeply into the question of glaciation—enormous as have been the effects of ice in this and other countries—there are many who cannot but feel that the ice-caps invoked almost transcend our powers of belief, and who will be grateful to any astronomer or mathematician who will bring the pole

[1] Lyell's "Principles," 11th edition, vol. ii. p. 209.

round which they were generated, somewhat nearer to our doors.

There is yet one point on which, before quitting the subject, I may add a few words. Sir J. W. Lubbock, in the paper from which I have already quoted so much, has hinted at the possibility of some want of homogeneity in the constitution of the globe, so that in cooling, the position of the axis of rotation may have changed. The varying amount of subterranean heat and volcanic energy in the same region at different periods of the earth's existence has frequently been commented on, as has also the varying degree of subsidence or elevation in the same tract at different times. The forces, whatever they may be, to which these upward and downward movements are due, have, as Sir Charles Lyell has remarked, "shifted their points of chief development from one region to another, like the volcano and the earthquake, and are all, in fact, the results of the same internal operations to which heat, electricity, magnetism, and chemical affinity give rise."

Whether changes in the specific gravity of enormous masses of rock in consequence of their being heated would be of sufficient degree to disturb the equilibrium of the globe, is a difficult question; but the remarkable position of the magnetic poles of verticity with regard to the actual poles of the earth, and the distribution of the magnetic force over the earth's surface may, as has been suggested to me by Capt. F. J. Evans, F.R.S., have some geological significance. These poles are in lat. 70° N., long. $96\frac{2}{3}°$ W., and in lat. $73\frac{1}{2}°$ S., long. $147\frac{1}{2}°$ E. If we draw a circle around the globe, cutting these two points, we find that the magnetic poles, instead of being 180° apart, are only about 165° distant in one direction, while they are about 195° in the other. In like manner the magnetic equator, or line of no dip, differs considerably in position from the terrestrial equator, being drawn about 15° to the south over South America, and about 10° to the north over Africa, and in passing the great Asiatic continent. There is also this singular circumstance, which was insisted upon by Sir Edward Sabine nearly forty years ago—viz., that if the globe be divided into an eastern and a western hemisphere by a plane coinciding with the meridian of 100° and 280°, the western hemisphere, or that comprising the Americas and the Pacific Ocean, has a much higher magnetic intensity distributed generally over its surface, than the eastern hemisphere, containing Europe and Africa and the adjacent part of the Atlantic Ocean. The points of the greatest intensity of the magnetic force, moreover, do not correspond with the magnetic poles, as there are two such foci in the northern hemisphere (those of America and Siberia) making it probable that there are two also in the southern hemisphere.

Such facts would seem more in accordance with a want of uniformity in the inner constitution of the globe than with its being a body all the parts of which are arranged in perfect symmetry. Some abnormal features in the direction of gravity in different parts of the world seem also to afford corroborative evidence to the same effect. The subject is one of perhaps too theoretical a character for the geologist to approach; but if any definite connection could be established between terrestrial magnetism and the internal constitution of the globe, we might, possibly, be justified in drawing the inference from its phenomena, that there are forces in operation in the interior of the earth by which its equilibrium may have been disturbed, and its axis of revolution thus caused to change in position.

(To be continued.)

NOTES

The Italian naturalist Beccari is again in New Guinea, exploring the north coast near Humboldt's Bay, along with an expedition sent out by the Governor-General of the Dutch Colonies. Of his former companion, D'Albertis, now at Yule Island, near the south-eastern extremity of New Guinea, we regret to hear that one of his collections from that district, containing about 35,000 insects and 700 reptiles, has been lost on its transit from Cape York. The bird-skins were, fortunately, not sent by the same vessel, and are therefore safe.

The Paris Observatory has received for January last Meteorlological observations made six times each day, at the Norma Schools, at the following thirty-four places:—Albertville, Alençon, Amiens, Aurillac, Avignon, Beauvais, Besançon, Bourg, Bourges, Caen, Carcassonne, Chalons, Chartres, Chaumont, Clermont, Commercy, Dragnignan, Foix, Grenoble, Le Mans, Le Puy, Loches, Lons-le-Saulnier, Mâcon, Melun, Mirecourt, Nimes, Orléans, Parthenay, Périgneux, Privas, Rouen, Troyes, and Villefranche. The importance of this valuable system of observation in its bearings on the peculiarly difficult problem of the meteorology of France, it would be difficult to over-estimate, especially when taken in connection with the numerous observers of thunder-storms and other phenomena requiring few or no instruments for their observation, whose services are being secured in different departments.

Prof. Cantoni has intimated to the Permanent Committee appointed by the Meteorological Congress of Vienna that the Italian Government has been pleased to intimate its readiness to invite the countries which were represented at Vienna to attend a Meteorological Congress in Italy in the autumn of 1877.

The Permanent Committee of the Vienna Meteorological Congress have announced their intention to hold their next meeting in London, in Easter week, commencing April 18 next.

Nine Lectures on the Shoulder-Girdle and Fore Limb of Vertebrata, will be delivered in the Theatre of the Royal College of Surgeons, on Mondays, Wednesdays, and Fridays, at 4 P.M., commencing on Monday, March 6, 1876, by Professor W. K. Parker, F.R.S.—Lecture I. March 6. The Vertebrate Skeleton. II. March 8. Shoulder-girdle and Fore Limb of Fishes. III. March 10. Shoulder-girdle and Fore Limb of Fishes. IV. March 13. Shoulder-girdle, Fore Limb, and Sternum of Amphibia. V. March 15. Shoulder-girdle, Fore Limb, and Sternum of Reptiles. VI. March 17. Shoulder-girdle, Fore Limb, and Sternum of Birds. VII. March 20. Shoulder-girdle, Fore Limb, and Sternum of Mammals. VIII. March 22. Shoulder-girdle, Fore Limb, and Sternum of Mammals. IX. March 24. Summary and conclusion.

The following is the business to be brought before the Half-Yearly General Meeting of the Scottish Meteorological Society to-day:—1, Report from the Council of the Society; 2, Report from the Ozone Committee; 3, The Salmon, Grilse, and Trout Fishings of the Tweed, in relation to Meteorology, by G. L. Paulin, Esq., and the Secretary; 4, Report from the Herring Committee.

The following memoirs and reports of the United States Geological and Geographical Survey of the Territories, under the direction of Prof. Hayden, are now in the press, and will be issued during 1876:—1. Monograph of the Rodentia of North America, by Elliott Coues and J. A. Allen. Quarto, about 500 pages, with numerous illustrations. 2. Monograph of the Geometrid Moths, by Dr. A. S. Packard, jun. 350 pages quarto, with 13 plates. 3. The Fossil Invertebrata of the Western Territories, by J. B. Meek. 600 pages quarto, and 45 plates, with numerous woodcuts in text. 4. The Fossil Flora of the Lignitic group of the Western Territories, by Leo Lesquereux. 65 plates, quarto. 5. The Ethnography and Philology of the Hidatsa Indians (Minnetarees of the Upper Missouri). 400 pages, octavo. 6. Annual Reports of the Survey for 1874 and 1875. 7. Bulletin of the Survey for the year 1876; several important articles in press. Other works are in process of preparation, and may be printed before the close of the year.

The *Bulletin* of the United States Geological and Geographical Survey of the Territories, Prof. Hayden in charge, has just issued Nos. 5 and 6, which close the year 1875. In No. 5, there are nine articles on various subjects of Geology and Natural History. In No. 6 there are four articles, with table of contents and complete index. It is suggested by Prof. Hayden that the two *Bulletins* of 1874 be bound with those of 1875, as Volume I. The index and title-page have been made with this idea in view. Volume I. will then comprise about 600 closely printed 8vo. pages, with 26 plates, sections, &c.

THE Cincinnati Observatory, since its reorganisation, under the charge of Mr. Ormond Stone, has again assumed a satisfactory position among kindred institutions in the United States. A School of Astronomy has been established, with quite a number of pupils. The double-star observations made by Prof. Mitchell have been reduced, and are ready for the printer. They embrace between 300 and 400 observations, made during the years 1846, 1847, and 1848. A series of double-star measurements has also been entered upon, restricted to those south of the equator, with a result of bringing to light quite a number of new close double stars.

THE first annual report of the Chicago Botanical Garden has been published. A plan has been prepared for the permanent arrangement of the entire ground. At the date of the report living specimens of ninety-five species of native plants had been placed in the garden, and seeds of 456 species collected in sufficient quantity for exchange.

WE understand that Dr. J. Gray McKendrick intends offering himself as a candidate for the chair of Physiology in Glasgow University, when Prof. A. Buchanan's intimated intention of resigning that chair has been carried into effect.

M. PAUL BERT has offered a prize for the best means of protecting the lives of aëronauts and mountain-climbers in circumstances where cold and rarefaction of the air become dangerous. The prize offered by M. Bert is a 20*l*. gold medal, and the competition is open up to December 31, 1876.

THE papers read on Monday evening at the Royal Geographical Society were, "On the Shueli Valley of Burmah," by Mr. Ney Elias; and "Afghan Geography," by Mr. C. R. Markham. The paper of Mr. Ney Elias described an alternative route into China to that which Mr. Margary had unfortunately taken, and been murdered. In introducing the second paper, on "Afghan Geography," Mr. Markham stated that its materials had been collected from the journals of the late General Lynch, compiled in Afghanistan. The paper gave full details of the history, geography, and antiquities of Afghanistan. General Lynch described the country through which he passed as being full of lovely valleys, inhabited by a gentle and hospitable people, as studded with mines of gold and silver and coal, as teeming with fertility, and as being rich in ancient monuments, in inscriptions, and in sculpture. A map of Afghanistan is being prepared in the War Office, embracing all the existing materials, and that map when published will show how many gaps in our geographical knowledge of Afghanistan still remain to be filled up.

THE *Bulletin* of the French Geographical Society contains a paper by M. V. A. Malte-Brun, giving an appreciative and sympathetic account of the organisation of the English Arctic Expedition and its progress up to the latest news received. M. Malte-Brun hopes to see the day when a French Expedition will set out for the North Pole. Abbé David's Second Voyage of Exploration in Western China, 1868–1870, is described, and M. J. Codine gives an account of the discovery of the African Coast from Cape St. Catherine to the Great Fish River by the Portuguese during the years 1484-1488.

ACCORDING to the *Annuaire* for 1876, there appear to be five English Academicians and twenty-nine English correspondents of the Institute of France. As Academicians in Science are Prof. Owen and Sir G. B. Airy; as Correspondents in the Class of Science are Professors Sylvester and Adams (Cambridge), Sir T. MacLear, Rear-Admiral Richards, General Sabine, Dr. J. P. Joule (Manchester), Dr. E. Frankland, Prof. A. W. Williamson, Prof. W. H. Miller (Cambridge), Dr. Hooker (Kew), Dr. W. B. Carpenter, Dr. Huggins, and Mr. Lockyer.

THE *Morgenblad* of Christiania states that a singular phenomenon was observed there after a recent violent storm. A number of worms were found crawling on the snow, and it was impossible to find the places from which they had issued, everything being frozen in the vicinity. Similar circumstances were reported from several places of Norway.

M. CYBOULSKY, a mining proprietor in Siberia, is said to have given a sum of 100,000 roubles to help the Government to found the Tomsk University.

THE number of students registered in the Paris Faculty of Medicine this year is 6,500, the largest number yet reached. On February 22, the Municipal Council of Paris voted a sum of six millions of francs for the construction of new buildings round the old ones belonging to the Faculty. The property of the buildings now in existence has been given up by the State to the City of Paris on the express condition that they should always be devoted to the Faculty of Medicine.

MANY of our readers, we are sure, will rejoice to hear that a movement is on foot in Germany to abolish the crabbed printed German alphabet and adopt Roman type. We sincerely wish the movement may lead to the desired result, and that it will extend to the still more vexatious written alphabet.

A NEW scientific periodical entitled *Electricité* has been issued in Paris, under the patronage of Count Halley d'Arroz, director of the International Electrical Exhibition of 1877. It will be profusely illustrated, and will be used by the Commission of Organisation as one of its official organs.

THE Committee appointed by the Préfet de la Seine to superintend the construction of lightning conductors in Paris has been changed into a permanent one. A sum of 8,000*l*. has been appropriated by the Municipal Council for reconstructing all the lightning conductors in Paris, or at least all those which may be found defective or inefficient. This sum is a first instalment, as the whole of the work, it is supposed, will cost 50,000*l*., although the Committee has not recommended the use of copper conductors. It is deeply to be regretted that the teachings of Sir Snow Harris are not better understood in France, as the Committee has adopted a number of excellent recommendations. Until the appointment of the Committee lightning conductors were constructed by ordinary blacksmiths, under the superintendence of architects who knew nothing of physics. A competitive adjudication took place on Feb. 19 between a number of competent electricians for the construction of all the lightning conductors on the Paris municipal monuments. The successful competitor is M. Grenet, the well-known electrician. A *cahier des charges* with seventy carefully-drawn provisions has been published. The electric continuity of conductors must be tested yearly, and the contractor will be paid by instalments, so that his claim will be cleared up only when the efficiency of his work shall have been tested during a certain number of years. The platinum cone has been abolished and replaced by a copper cone. The quality of the iron, as well as of the copper and solder, is to be tested by chemical analysis. The insulation of rods has been abolished as being useless. The Commission has diminished the diameter of protection area, which was supposed to be twice the height, and has reduced it to 1·45. The consequence is that rods are to be multiplied. The principal provisions of the 1876 *cahier des charges* have been drawn in accordance with the instructions published by the French Academy of Sciences in 1825.

WE have received a copy of the rules adopted at a recent meeting of the newly-formed Mineralogical Society of Great Britain and Ireland. The object of the Society is the study of mineralogy and petrology, and it will be composed of ordinary members, associates, and corresponding members. Besides general and annual meetings, local meetings may be held at any time and place as may be agreed upon by six members or associates. The Society will publish a journal. The President is

Mr. H. C. Sorby, F.R.S., the Secretary, Mr. R. P. Grey, F.G.S., and the Council is composed of men whose names are well-known in science.

THE head of the publishing firm of Didot, died a few days ago at the age of eighty-six. The deceased was a member of the Academy of Inscriptions, and under his direction the firm published a number of valuable scientific books. The Didot firm hold the office of printers to the French Institute, M. Gauthier Villars being only printer to the Academy of Science.

THE second annual meeting of the members of the Scientific Club was held at the Club House, Savile Row, on Thursday, the 17th Feb. Major F. Duncan, D.C.L., Chairman of the Committee, presided. The Report of the Committee, showing the rapid progress the Club had made during the past year, was unanimously adopted.

WE are asked to state that supplemental meetings for the reading and discussion of papers by students of the Institution of Civil Engineers have been appointed for the following Friday evenings:—February 25, March 3, 10, 17, 24, and 31. The chair will be taken at 7 o'clock on each evening, and successively by Dr. Pole, F.R.S., Sir W. G. Armstrong, C.B., F.R.S., Mr. H. Hayter, Mr. Woods, Mr. Brunlees, and Mr. Berkley, Members of Council.

AMONG the papers in the published "Proceedings" of the Belfast Natural History and Philosophical Society for 1874–75 are the following:—Presidential Address on atoms and automata, by Joseph J. Murphy, F.G.S.; On some Irish Palæozoic fossils, by Rev. John Grainger, D.D.; On the water-bearing strata between Moira and Lurgan, by Robert Young, C.E.; On the geographical distribution of mammals, by R. O. Cunningham, M.D., Professor of Natural History, Queen's College, Belfast; A suggestion on chemical notation, by the president, Joseph John Murphy, F.G.S.; Further notes on some of the swimming birds frequenting Belfast Lough, with special reference to the Great Northern Diver, by R. Lloyd Patterson.

THE additions to the Zoological Society's Gardens during the past week include a Virginian Eagle Owl (*Bubo virginianus*) from N. America, presented by Mr. H. Knight; two Widgeons (*Mareca penelope*), a Common Wild Duck (*Anas boschas*), a Lesser Black-backed Gull (*Larus fuscus*), three Herring Gulls (*Larus argentatus*), two Common Gulls (*Larus canus*), three Black-headed Gulls (*Larus rudibundus*), European, presented by Mr. C. Clifton; a Common Otter (*Lutra vulgaris*), European, received in exchange; a Darwin's Pucras (*Pucrasia darwini*) from China, a Rose-crested Cockatoo (*Cacatua moluccensis*) from Moluccas, deposited; a Zebu (*Bos indicus*) born in the Gardens.

SCIENTIFIC SERIALS

THE *American Naturalist* has changed its form this year. In future it is to be published by Messrs. H. O. Houghton and Co., Cambridge, Mass., under the editorship of Dr. A. S. Packard, jun. The amount of matter is increased, and the articles will be of a more popular nature than previously. A department of Geography and Travel is added, and Dr. R. H. Ward, of Troy, N.Y., will superintend the Microscopy. There seems to be considerable difficulty in the production of a science journal in America, and we think that there is still room for improvement. The first paper in the January number is on "Burs in the Borage family," by Prof. Asa Gray, in which a new form, named *Harpagonella*, is described, having been obtained by Dr. E. Palmer, from Guadalupe Island, off Lower California.—The Rev. S. Lockwood describes the habits of the "Florida Chameleon" (*Anolis principalis*).—Mr. David Scott writes on the proper specific name of the Song Sparrow, *Melospiza fasciata* (Gondin), not *M. melodia* (Wilson).—Mr. J. C. Russell shows of what great value the New Zealand Flax (*Phormium tenax*) would be if a method of cleaning it could be discovered.—Mr. J. A. Allen discusses the availability of certain Bartramian names in ornithology, and opposing Dr. Coues' desire to establish some of them. A list is given of those of Bartram's names which Dr. Coues wishes to re-establish.—Prof. N. S. Shaler describes the first session of the Harvard Summer School of Geology.—Ancient ruins in S.W. Colorado are illustrated and described from photographs taken by Mr. W. H. Jackson, the photographer to Prof. Hayden's United States Geological Survey of the Territories, including a house, a round tower, and a square one of Indian construction.—Reviews of Sach's "Botany" (English translation) and Caton's "Summer in Norway," with badly-engraved drawings, are given, together with notes, &c., which conclude the number.

Poggendorff's Annalen der Physik und Chemie., No. 11, 1875. —The tuning-fork has become an important instrument in physical observations, and this number of the *Annalen* begins with a description of experiments by Dr. Ettingshausen, with a stroboscopic tuning-fork apparatus, in which the motion of an electromagnetically excited fork is observed through slits arranged in connection with another fork of nearly the same pitch placed near it. The following are some of his results:—Compared with pendulum motion, that of tuning-forks is somewhat retarded in the inward course, and accelerated in the outward. The vibration time considerably increases with increase of the time of closure of the circuit. The electro-magnetically excited fork vibrates (where the divergences are not too great) more quickly than if the vibrations were caused by elasticity alone. With equal amplitude the duration of vibrations increases slightly with the time the apparatus has been in action; and it decreases with increasing density of the surrounding air.—Electric phenomena occupy a large share of attention in this number, especially various actions of the spark. M. Peters, extending the researches begun by M. Antolik on "gliding" electric sparks, describes effects obtained by letting the spark glide on smoked paper brought near the machine on a glass table. The trace of the flash showed three different parts, each about a third of the whole length. In the *positive third* were numerous branchings outwards from a middle part, which consisted of a succession of parallel dark and bright strips (the darkest in the middle); the *negative third* showed no branchings, and the parallel strips were in reverse order; the *middle third* was distinguished by a greater width and brightness. M. Peters seeks to account for these phenomena. In another note he points out some differences between spark-forms from large inductors and those from the Holtz machine.—A paper by MM. Mach and Wosyka, also suggested by Antolik's experiments, furnishes reason for thinking that the soot figures produced are due to air motions, and especially sound motions.—Again, M. Riess gives an account of the phenomenon of weak electric sparks (as he called them), which differ from the ordinary strong sparks in form, light, sound, and other properties. A mode of producing them was formerly described. He observes that the greater length of the negative electrode has no essential connection with their production, and that, in regard not only to length, but to light and sound, they are independent of the composition of the circuit in which they occur.—Some striking new light phenomena of electricity are also described by M. Holtz.—In a note on the dielectric constants of liquids, M. Silow furnishes experimental proof of a proposition of Helmholtz with regard to attraction of two electric masses situated in an insulating medium, and a valuable paper by M. Herwig treats of the magnetisability of cylindrical iron pipes in different directions; he considers that in addition to the forces hitherto taken into account, there are further molecular magnetic forces which are of the greatest importance. These act within a magnetic line in the direction of the entire magnetisation, and in interrupted portions of a magnetic line in the contrary direction.—MM. Hildebrand and Norton endeavour to fill up some gaps in our knowledge of the properties of metallic cerium, lanthanum, and didymium; having obtained these elements by the help of the electric current, according to Bunsen's method, in quantities of nearly fifty grammes.—A note on impact machines is contributed by M. Sedlaczek.

SOCIETIES AND ACADEMIES

LONDON

Geological Society, Feb. 18.—Annual General Meeting.—John Evans, F.R.S, president, in the chair.—The Secretary read the reports of the Council and of the Library and Museum Committee for the year 1875. The position of the Society was

described as very satisfactory, although owing to various extraordinary expenses, the expenditure of the year was considerably in excess of its income. The Society was stated to be in a prosperous state, and the increase in the number of Fellows to be greater than in any previous year. The report also referred to the bequest by the late Sir Charles Lyell of the die of a medal and of the sum of 2,000*l.*, a bronze copy of the former and the interest of the latter to be given annually or from time to time by the Council as a mark of honorary distinction to some person or persons who shall be regarded as having aided the progress of Geological Science. It was also announced that Dr. Bigsby, F.R.S., has offered to found a bronze medal to be given in alternate years as an incentive to the study of Geology. The President then presented the Wollaston Gold Medal to Professor Huxley, F.R.S.; the balance of the proceeds of the Wollaston Donation Fund to Mr. J. Gwyn Jeffreys, for transmission to Professor Giuseppe Seguenza, of Messina, F.C.G.S.; the Murchison Medal to Professor Ramsay for transmission to Mr. A. R. C. Selwyn, F.R.S,; the balance of the Murchison Geological Fund to Professor Ramsay for transmission to Mr. James Croll; and the first Lyell Medal and the entire proceeds of the Fund to Professor Morris, F.G.S. The President then proceeded to read his anniversary address, an abstract of which we give on another page. The ballot for the Council and Officers was taken, and the following were duly elected for the ensuing year:—President: Prof. P. Martin Duncan, F.R.S. Vice-Presidents: Sir P. de M. Grey Egerton, Bart. F.R.S.; R. A. C. Godwin-Austen, F.R.S.; J. W. Hulke, F.R.S.; Prof. A. C. Ramsay, F.R.S. Secretaries: David Forbes, F.R.S.; Rev. T. Wiltshire. Foreign Secretary: Warington W. Smyth, F.R.S. Treasurer: J. Gwyn Jeffreys, F.R.S. Council: H. Bauerman; Rev. T. G. Bonney; W. Carruthers, F.R.S.; Frederick Drew; Prof. P. Martin Duncan, F.R.S,; Sir P. de M. Grey Egerton, Bart, F.R.S.; R. Etheridge, F.R.S.; John Evans, F.R.S.; David Forbes, F.R.S.; R. A. C. Godwin-Austen, F.R.S.; Henry Hicks; J. W. Hulke, F.R.S.; J. Gwyn Jeffreys, F.R.S.; Prof. T. Rupert Jones, F.R.S.; J. W. Judd; Prof. J. Morris; Prof. A. C. Ramsay, F.R.S.; Samuel Sharp, F.S.A.; Warington W. Smyth, F.R.S.; Admiral T. A. B. Spratt, F.R.S.; W. Whitaker; Rev. T. Wiltshire, F.L.S.; Henry Woodward, F.R.S.

Linnean Society, Feb. 17.—J. Gwyn Jeffreys, F.R.S., vice-president, in the chair.—Dr. D. D. Cunningham, Mr. W. C. Tuely, Mr. C. M. Wakefield, and Mr. C. F. White were elected Fellows of the Society.—"Additional observations on Ants," by Sir John Lubbock, Bart. In this paper Sir John communicated some further experiments in continuation of those contained in his last memoir. As regards the cases in which when an ant has found a store of food, other ants make their way to it, he commenced by referring to some of his recent observations. To the edge of a board communicating with the nest he fastened three parallel strips of paper about a foot long (G, H, and I). One of these (G) led to a shallow glass tray containing a number of larvæ. The object of this was to ascertain how many ants would find the larvæ for themselves under such circumstances, and as a matter of fact none did so. On the middle strip (H), near the centre, and at right angles with it he placed two strips of paper 2 inches long, one (K) leading to another shallow tray containing larvæ (F), while the other (L) rested on the third strip of paper (I). He then took an ant (*F. nigra*), marked her, and put her on the tray F. She immediately took a larva, and went away to the nest along the strip of paper H. Now it is obvious that by always causing the marked ant to cross from the strip of paper, H, to the larvæ over a particular bridge of paper, K, and if whenever a stranger came, the paper bridges, K and L, were reversed, it would be shown whether the other ants who came to the larvæ had had the direction and position explained to them. In such a case they would go right notwithstanding the interchange of the paper bridges: but if they found their way by tracking the footsteps of the first ant, they would pass over the paper bridge K, and thus be led away from the larvæ to the strip of paper I. The result was that out of 79 strange ants which came up to the point at which the paper bridges diverged, 24 went straight along the strip of paper, 11 took the right bridge to the larvæ, while 44 were misled and went over the paper bridge K away from the larvæ to the strip of paper I. He then slightly altered the arrangement, transfixing one end of the two paper bridges by a pin, and so fastening them by one end to the strip of paper H, the other ends free, that each of them could be turned either to the larvæ or to an empty glass tray. When the marked ant came he turned one paper bridge, K, to the larvæ, the other, L, to the empty tray; while whenever any other ant came he turned the bridges, so that K led to the empty tray and L to the larvæ. Under these circumstances, seventeen ants which came along the strip of paper H, without a single exception, went over the bridge K to the empty tray. He then varied the experiment by leaving the paper bridge K loose as at first; but instead of having a separate bridge L, he cut the strip of paper H into two pieces, H′ and H″. Then when a strange ant was coming, he rubbed his finger two or three times over the bridge K, so as to remove or at least confuse the scent. As soon as the ant had passed over the first part, H′, of the strip of paper H, and had arrived on the part H″, he took up the piece H′ and placed it where the paper bridge L had been in the previous experiments, *i.e.* so as to connect the end of H with the empty glass tray. By this arrangement the bridge K was left in its place, and, on the other hand, there was a bridge which the marked ant had crossed and recrossed as often as K, but which led away from the larvæ. Under these circumstances, out of forty-one ants which found their way to the end of the strip H, and within two inches of the larvæ, fourteen only passed over the bridge K to the larvæ, while twenty-seven went over H′ to the empty tray. Taking these observations altogether, out of 150 ants which came to the end of the strip of paper H, and thus within two inches of the larvæ, only twenty-one took then the right turn and arrived at their destination. These experiments therefore certainly seem to show that when ants flock to a treasure of food which one of them has discovered, they either accompany one another or else track it out by scent. The fact, therefore, is by no means an evidence of any high intelligence, or any complex system of communication, but is merely an instance of instinct, little higher than that which is found in other social animals. On the other hand, that some higher power of communication does exist, seems, however, to be obvious from some of the facts recorded in Sir John's previous paper. In the latter part of his present paper the author narrated a variety of experiments on the senses of ants, and on their power of recognising friends. A lively discussion followed the reading of the paper, in which Messrs. Lowne, Romanes, Mivart, and McLachlan, &c., took part.—Dr. Cobbold gave a notice of and exhibited several specimens of the new human fluke discovered by Prof. J. F. P. McConnell, of Calcutta. This parasite was first described by Dr. McConnell in the *Lancet*, Aug. 21, 1875. Prof. Leuckart, of Leipsic, unaware that the species had been already named, *Distoma sinense*, proposed the name *D. spatulatum* for it, which thus sinks into a synonym. Dr. Cobbold pointed out how the transparency of the specimens permitted all the internal organs to be well seen, and thus their structure could not readily be confounded with any other known species. The Entozoa found by Dr. Kerr, of Canton, and described by Prof. Leidy, did not belong to the above species, but to the great human fluke (*Distoma crassum*) discovered by Prof. Busk. Details of this last-named parasite have just been published in the Society's Journal.—A paper was read by Dr. John Anderson "On the cloacal bladders, and on the peritoneal canals in Chelonia." The former seem first to have been described by Bojanus in *Emys europœa*, but since have received sparse attention. Dr. Anderson has ascertained their presence in a number of Asiatic genera and species, though they do not occur in others, *Testudo*, *Trionyx*, &c., to wit. He suggests these organs may be related to the habits of life, as it appears they are confined to those animals semi-terrestrial and semi-aquatic in habit, the true land and essentially water-living Chelonians being unprovided with them. Although known that some Chelonia draw in and eject water from the cloaca, the precise functions of the pouches in question have not been clearly determined.—The peritoneal canals have received elucidation from Cuvier, Is. Geoffroy, and Martin, but as to their relations, functions, and homology, Dr. Anderson is at variance with these *savans*. Basing his views on experimental injection and otherwise, he regards them as not connected with the generative functions, but rather agrees with Dumeril and Bibron as to their being accessory and subordinate to transpiration. He believes they have a distinct origin from the Mullerian ducts, and are homologous with the abdominal pore of Selachians and Ganoids.—The chairman called attention to a letter from the Director of the South Kensington Museum, in which the Committee of Council of Education desire the co-operation of the President and Fellows of the Linnean Society toward furnishing objects on loan for the forthcoming Exhibition of Scientific Apparatus.

Anthropological Institute, Feb. 22.—Mr. J. Park Harrison, treasurer, in the chair—The Director, Mr. E. W. Braybrook, read a paper by the Rev. John Earle, M.A., on the Ethnography of Scotland. The author alluded to the great similarity in the physiognomy of the Norwegians and the Scotch as exhibited in photographic portraits, the likeness between the two peoples having also struck Dr. Beddoe. The conquest of the northern parts of Scotland, and especially Caithness, (Icelandic Kata-ness=ship promontory) is celebrated in the Sagas: and the author believed that the "harrying west" of the Danes along the eastern coast of Great Britain extended at least as far as the Firth of Forth. Vigfusson's Icelandic Dictionary supplies materials to illustrate numerous striking features in the Scottish language and the Norsk, *e.g.* bairn, carline, eldine, ettle, fey, (make); gar, greet, (to weep); speer, firth, &c. The Danish and Norsk districts in Scotland are the meeting ground of the great and divergent branches of the Gothic family—the Teutonic and the Scandinavian. In the Scottish language the Norsk element is almost undiluted with Saxon, and we gain from it Ethnological evidence, which recorded history does not distinctly afford. An analysis of the language Mr. Earle believes would bring out additional proofs that it is the permanent expression of the overlapping of the races above alluded to.

BERLIN

German Chemical Society, Feb. 14.—A. W. Hofmann, president, in the chair.—E. Paterno and G. Briosi made preliminary communications on hesperidine obtained from oranges; 1,000 oranges yield less than 150 grains of the pure substance.—A. Ladenburg has found that isomeric diamines are acted upon by nitrous acid in very different ways. Parametatoluylendiamine yields a well crystallised body $C_7H_7N_3$, amidoazotoluylene.—T. v. d. Hoff finds that succinic acid obtained in reducing malic acid with HI is optically inactive.—V. Wartha has discovered indigo in commercial litmus.—P. Weselsky described a reaction of phloroglucine. Mixed with nitrate of toluidine and nitrite of potassium it yields a precipitate of the colour of cinnabar.—A. Claus has found that the body until lately known as crotonchloral when treated with cyanide of potassium, yields not only chlorocrotonic acid $C_3H_4ClCO_2H$, but also a bibasic acid $C_3H_4(CO_2H)_2$, and tricarballylic $C_3H_5(CO_2H)_3$.—The same chemist described combinations of sulfo-urea with bichloride of mercury, and with oxalic acid.—R. Hasevcleors, in using Deacon's chlorine-apparatus has remarked that the amount of HCl decomposed, sunk within six weeks from 80 to 2 per cent. He found the hydrochloric acid passing through the apparatus to be contaminated with sulphuric acid, and believes this to be the reason of the deterioration of the process. Sulphuric acid, so he believes, is decomposed into sulphurous acid, and oxygen and the sulphurous acid is reoxidised by retransforming the chlorine into hydrochloric acid:—

$$SO_4H_2 = H_2O + O + SO_2$$
$$SO_2 + Cl_2 + 2H_2O = SO_4H_2 + 2HCl.$$

A support of this view is found in the fact that manufacturers that take great care in introducing hydrochloric free from sulphuric acid, are able to use the process for a comparatively longer period.—M. Neneky, who by the action of formic and acetic acids on guanidine obtained formo-guanamine $C_3N_5H_5$, and aceto-guanamine $C_4N_5H_7$, has also obtained two isomeric bases $C_6N_5H_{11}$ by the action on guanidine on butyric and isobutyric acids. Aceto-guanamine, by taking up one or two molecules of water under the influence of potash, respectively yields guanide $C_4N_4H_5O$; guanamide $C_4N_3H_5O_2$. By oxidation it yields cyanuric acid $C_3N_3H_5O_3$.—E. Bandrowsky, treating guanidine with valerianic acid and caproic acid, obtained the corresponding guanamines, $C_7N_5H_{13}$ and $C_8N_5H_{15}$.

PARIS

Academy of Sciences, Feb. 14.—Vice-Admiral Paris in the chair.—The deaths of MM. Andral and Seguier were announced.—The following papers were read:—On the ethers of hydracids, by M. Berthelot.—On the formation of amides, by M. Berthelot.—On hyposulphite of potash, by M. Berthelot.—Memoir on the approximation of functions of very large numbers and on an extensive class of developments in series (second part), by M. Darboux.—Vibrations of a homogeneous solid in equilibrium of temperature, by M. Felix Lucas.—On the movements of the heart when it is submitted to artificial excitations, by M. Marey. The results obtained show that the heart is refractory to excitation during the greater part of its systolic phase. The systole produced (by excitation) is greater the longer its interval from the spontaneous systole which precedes it. After each systole produced, there is a compensating repose which restores the temporarily altered rhythm of the heart. This is important as confirming a law the author believes he has established, viz., that the work of the heart tends to remain constant.—On deviations from the laws relating to gases, by M. Mendéléeff.—On isomerous rosanilines, by M. Rosenstiehl. There are three of these, one derived from 1 molecule of aniline and 2 molecules of toluidine; another, 1 of aniline and 2 of pseudo-toluidine; the third, 1 of aniline, 1 of toluidine, and 1 of pseudo-toluidine; the latter constitutes, for the most part, commercial fuchsine.—On the optical inactivity of the reducing sugar contained in commercial products, by MM. Aimé Girard and Laborde.—On a new element in the determination of chimi-calories, by M. Maumenè. Very various liquids undergo a molecular alteration (readily revealed by chemical action) without their nature being changed; the purely physical influence of heat gives them a sort of temper (*trempe*), during which their chemical actions produce extraordinary numbers of chimi-calories. Olive oil recently heated to about 300° behaves no longer like its former self when treated with hot acid, but it is not perceptibly altered in colour, odour, or density.—On a new acid pre-existing in the fresh milk of mares, by M. Duval. It appears to be distinct from hippuric acid, and the author proposes to call it *equinic* acid.—On the aptitude of oysters for reproduction from the first year, by M. Gerbe. Observation shows this to be a fact. Among these precocious mothers there are some whose shell, in transverse diameter, measures hardly 25 mm. Hence the prosperity of the reproducing portion of a natural oyster bed, does not depend only on the presence of large oysters. The quantity of eggs, indeed, is generally in proportion to the size of the oyster. Many oysters, especially the young, propagate twice in the season, under favourable conditions. The laying of eggs occurs at long intervals, possibly corresponding to lunar phases.—Reply to a note of M. Arm. Gautier, relative to the *rôle* of carbonic acid in the coagulation of blood, by MM. Mathieu and Urbain.—Description of the diplometer, by M. Landolf. This is an instrument for measuring the diameter of an object at a distance and independently of its movements.—On the origin and mode of generation of atmospheric whirlwinds, and on the unity of direction of their gyratory motion, by M. Cousté. The whole mechanism of whirling movements in the atmosphere depends on two causes, gravity and heat; the weight of the air drives vertically from below upwards the less dense water-vapour which the heat has produced; and further, the weight of the air causes this gas to be precipitated (in horizontal, or at least *inclined* directions into the vacuum which the vapour tends to leave behind it in rising.

CONTENTS

Erratum.—Vol. xiii. p. 328, last line, for *him* read *me*.

THURSDAY, MARCH 9, 1876

CAROLINE HERSCHEL

Memoir and Correspondence of Caroline Herschel. By Mrs. John Herschel. (London : John Murray, 1876.)

ASTRONOMY may justly claim to be one of the most comprehensive branches of human knowledge, not merely from the immeasurable extent of the region which it undertakes to investigate, but from its embracing in a common boundary, and directing towards a common end, mental processes and lines of study which otherwise would have found but little ground for convergence and combination. It is, perhaps, not generally understood how varied are the courses, or how distinct the attainments, of those who are comprehended under the general title of "astronomers," or how strong, more especially, is the demarcation between the pursuit of theory and the practice of observation. Very different are the requirements of Greenwich and Parsonstown. The collection of facts, and the investigation of the laws which are gathered from those facts, are entirely distinct processes, and though the qualifications demanded separately for each have occasionally been found in combination, yet more frequently they have existed in individuals who have had little in common besides the general end of their pursuit. Laplace or Clairaut would have exhibited but little aptitude for wielding the instruments of Slough, and many an eye that has rested with the liveliest interest on the magnificence of the lunar scenery, or the mysterious glories of those regions where the great Creator has "sowed with stars the heaven thick as a field," would pore in vain on a page of intricate analytical formulæ, or perhaps turn from it with a feeling of positive dislike and annoyance.

At the head of the observing class in his own day everyone will recognise the name of William Herschel. He did not, indeed, stand as prominently alone as was formerly supposed in the adopted country which was so justly proud of him, for he had left a worthy rival in his native land, where Schröter, armed at first with his opponent's instruments, and afterwards with those of Schrader of Kiel, was doing most earnest and faithful work in his own way. On the moon, indeed, and on Venus and some of the planetoids, Schröter not only held his own, but gained an advantage which has been more fully appreciated as years have passed away. But in the starry heavens, where Schröter was inefficient, Herschel was supreme; and in his hands sidereal and nebular astronomy started out at once into a prominence which it has since fully maintained. Before his time some forty double stars had been casually noticed; his catalogues comprised about 700; and the host of nebulæ grew in far higher proportion, from 103 in Messier's list, to 2,500, a great part of them most delicate and difficult objects. Nor was our own system without its corresponding enlargement, in a new and important planet at an unsuspected distance, with a train of most minute attendants, to say nothing of two additional satellites of Saturn: nor had the solar phenomena ever been so fully investigated or so clearly described. No wonder that the records of English science should adorn the name of Herschel with a pre-eminent glory—

> "Gloria sideribus quam convenit esse coævam,
> Et tantum cœlo commoriente mori."

But other talents, and those of a high order, were combined in the case of this illustrious man. Inheriting a family gift, he had been originally a musician of considerable eminence—not only the organist of a fashionable chapel in Bath, and sometimes giving thirty-five and thirty-eight lessons per week to lady-pupils, but rising above the ordinary level as a writer of good music. It is matter of great regret that much of his composition has been irrecoverably lost: but a portion seems to be still existing, and we earnestly hope may yet appear in a public form. It was, however, of more importance to one of the very first astronomers that he should also be one of the very first opticians of the age, and in Sir W. Herschel this was fully carried out. In him a consummate knowledge of practical optics aided the keen vision of the observer. Others had indeed attained great and perhaps equal perfection in the manufacture of reflecting telescopes. Those of the celebrated Short, though on the inferior Gregorian construction, were remarkable for their distinctness; nor had he shrunk from 12-inch apertures, or nominal powers, even in this case, of 100 per inch, though it may be feared that actual measurement would have considerably reduced their value. And as regards mere size, the French optician Noël, after many attempts, succeeded, in 1772, with a mirror of 2 feet, which, mounted as a Cassegrain, bore a power of 528, though with what distinctness does not appear, nor where the remains of this Colossus may be now. But the multitude of specula that Herschel had wrought—more than 400 of 7, 10, and 20-feet focus—before he succeeded to his satisfaction, and the wholly unprecedented effort that placed the 40-foot telescope at his command, merely constituted him the chief optician of his day; to this was added the special talent of acute and most persevering observation, which he possessed in very full development, and employed to the utmost, even to a very advanced age, and with a result exceeding all anticipation.

Any one, however, who has some practical acquaintance with the labour of observation with the larger class of telescopes, will readily perceive that such researches, especially when combined with such heavy and continuous optical work, could never have been accomplished alone. This must be eminently the case when far-stretching tracts of sky have to be explored for unknown objects; the distinct and equally important tasks of observing and recording are so incompatible as to be beyond the grasp of the most accomplished astronomer. Assistance must be had, and that no ordinary kind of assistance, but such as may really answer to its name—carelessness, or tardiness, or awkwardness being fatal in such a case to the idea of effectual aid. That Sir W. Herschel found in his sister Caroline such an assistant as materially contributed to his own success has long been familiarly known; but it has not been so generally understood how able was her co-operation, how laborious her night-watchings, how persevering her attention, how utterly unselfish in its absorbing and generous attachment her devotion to her brother's pursuits. It was to bring into due notice so uncommon a character, which

from its very constitution ever shunned the exposure of publicity, that the book now lying before us has been written. We will not predict for this memoir a brilliant but ephemeral popularity; it may be thought deficient in attractiveness by general and unscientific readers; and perhaps a very natural partiality may have led to the introduction of a good deal of unimportant and rather heavy detail; but it is a book full of interest for those on whose account we may suppose it to have been especially written; whose scientific tastes and leanings, particularly if connected with astronomical or optical pursuits, will awaken in them a ready sympathy with the difficulties, the labours, and the triumphs of those with whose domestic habits and inner life they are thus brought into familiar contact, and for the first time; for, as the authoress remarks, no good biography of Sir W. Herschel exists—a reproach, surely, to our astronomical literature.

As to the interest excited by the portrait of her own very remarkable and original character, exhibited in her own correspondence; how the talent, hidden during a neglected and almost menial youth—for she speaks of having tasted the drudgery of the scullery—was developed and cultivated by the brother who fully appreciated her abilities; how her unwearied industry and diligence could only be surpassed, if they were surpassed, by his own; how she gladly did his behests as a public singer; how they were for many years inseparable companions; how she attended upon him during the tedious polishing of his mirrors, often feeding him bit by bit when he was unable to leave off for meals, in one such instance for sixteen consecutive hours; how she prepared his astronomical work, watched with him through nights when the ink was frozen by her side, and calculated for him in days when others would have sought repose or amusement; as to all these evidences of talent and skill and patience, dedicated simply and humbly, and with the most complete disregard of health and even of personal safety, and utter abnegation of every selfish thought and feeling, to her dear brother's service, we would refer our readers to the book itself. In the portraiture of a very uncommon character they will assuredly not be disappointed.

But it contains also much interesting detail as to that brother's life, and draws a picture of his proceedings in many respects unlike what we, for our own part, had been used to suppose. Very little, we find, did he enjoy of that "retired leisure" which such a man should have had at command. His privacy is exhibited as mercilessly interrupted by the natural, but inconsiderate, curiosity of visitors. The munificence of his royal patron was interfered with very unjustifiably by "shabby, mean-spirited advisers." The labour and anxiety connected with the 4-foot mirrors, on which at one time no less than twenty-four men in two relays were kept polishing day and night, while he personally superintended the whole, and never allowed himself to sit down to table, told seriously on his health, and once caused his life to be for some time despaired of; and speaking of his latter days his sister remarks, "we have all had the grief to see how every nerve of the dear man had been unstrung by over-exertion; and that a farther attempt at leaving the work complete became impossible." Much of explanatory and connecting material would be required for such a memoir as is due to William Herschel; but what is here given is especially characteristic and valuable. We are led, while on the subject, to introduce a few anecdotes long ago communicated to us by one who in youth knew Sir William well, and which, we believe, are comparatively unknown. His regular after-dinner toast, according to the custom of those days, was "Success to astronomy." There was a vein of humour in his disposition, as is frequently seen combined with eminent talent; and on one occasion he sent his young companion upstairs to his wife's room to look at an extraordinary star, on which a telescope, which was called hers, was pointed. He did so, and found it was the figure of a star, fastened to, or represented in, the wall of Windsor Castle. When he had discovered the planet formerly called by his name, Sir Joseph Banks and other Fellows of the Royal Society attempted, to no purpose, to catch a sight of it. Finding this to be the case, he had a portable tube constructed of silk, packed it up with his mirrors, travelled to London, appointed a meeting with the doubters on the roof of Somerset House, and there exhibited to them the object which they had sought in vain; on which Sir Joseph took off his hat and made him a bow, an example which was followed by the rest of the company. It is greatly to be regretted that the biography of his illustrious parent was never taken in hand by one so especially qualified to fulfil the task as his equally gifted and equally celebrated son, some of whose beautiful letters, addressed to his aunt after her return to Hanover, form a great attraction in the volume of her Memoirs.[1] But we yet hope that the task may be accomplished, and that his most valuable papers, now stowed away, as it were, in the "Philosophical Transactions," may be published in a collected and more accessible form; and thus a monument raised to his well-earned fame, more permanent, at least as far as optics are concerned, than the works of his hands. For these, unfortunately, were of a perishable nature, owing to the defective character of the material which alone he could make subservient to his purpose. No specimen of the alloy of tin and copper employed can be expected to remain untarnished for any considerable time; and the restoration of its brilliancy can only be attained by the destruction of its original figure: if rendered by extraordinary skill as perfect as before, it will still not be the unaltered result of the great master's hand. We do not know whether a single mirror of Herschel's may now be remaining untarnished and untouched: an especially sad fate, we are reluctant to add, has befallen the much-valued 6-inch mirror which Caroline Herschel used so frequently, and bequeathed to the Royal Astronomical Society as an especially safe depositary for so precious a relic. Tarnished by a singular accident while in the temporary care of other parties, it was, we understand, attempted to be repolished without the Society's knowledge; but so unskilfully was this done, that it has not only lost its original figure, but now possesses none of any value at all; the very tube had to be patched to accommodate the lengthened focus; and the donor would hardly recognise her favourite instrument again.

One cannot but regret that such wonderful skill and

[1] There is a singular error in one of these letters (p. 288) describing the re-discovery of Enceladus, where *bdoro* has been printed for *below*. At p. 317 the word *tubes*, which has been introduced as a correction or explanation in one of Miss Herschel's letters, is a mistake.

labour should have been expended upon a material so little capable of doing it justice, when the employment of silvered glass would have given entire permanency to the beautiful curves which Herschel knew how to bestow. But that invention was reserved for Foucault at a later day. Had Sir W. Herschel known of it, the 4-foot mirror would not only have been of far easier workmanship, but would still be ready for a comparison of its merits, as to which there has been much discussion, with the productions of modern days. This, however, is rather matter of curiosity than of real use. It is no detraction from Herschel's well-deserved reputation to suppose that the four MS. volumes which he left behind, containing all the details of his experiments and processes, would be found to add little to the knowledge now possessed by our most successful reflector makers. As to metal-working, difficulties equal, and greater, have been encountered and vanquished by Lassell and the Earl of Rosse: as to silvered glass, Steinheil indeed has abandoned the undertaking, and of the quality of the great French reflectors we know little on this side of the Channel; but the near approach to perfection in the hands of English artificers, and especially of With (who, we are glad to hear, is contemplating an increase in his apertures), leaves no room for regret on that score. Never, probably, were reflecting telescopes more faultless than now; never could they challenge so fearlessly a comparison with the great achromatics of the day. May astronomers be found who shall be capable of working them to their fullest capacity and for their noblest end. But whatever future advances may be in store for us, whether in the optician's or the observer's hands, nothing in either respect will ever detract from the honour of Sir William Herschel, or of her whose memoirs we have now been perusing with so much interest. Her brother's place indeed might more easily be supplied: one equal to herself, as the most efficient, unwearied, self-denying, devoted of assistants we can scarcely expect to see again.

T. W. WEBB

MORESBY'S "NEW GUINEA AND POLYNESIA"

Discoveries and Surveys in New Guinea and the D'Entrecasteaux Islands. A Cruise in Polynesia and Visits to the Pearl-shelling Stations in Torres Straits by H.M.S. *Basilisk.* By Capt. John Moresby, R.N. With Maps and Illustrations. (London: John Murray, 1876.)

NEW Guinea has been much before the public recently. As our readers know it has been the field of a number of small exploring expeditions, the somewhat fragmentary results of which have only served to whet our appetite for more information. Most of these expeditions, under such men as Meyer, Beccari, D'Albertis, and Miklucho Maclay, have been occupied with the western part of the island, our knowledge of the eastern and larger half having been practically almost a blank. Capt. Lawson's wonderful work (NATURE, vol. xii. p. 83) with its abundance of astounding statements can scarcely be regarded as a contribution to our knowledge of the island, though it has made us still more anxious to know the truth about a land which, even in the present advanced state of geographical knowledge, seems to have unknown wonders to reveal. Quite recently we heard of the discovery of a large river debouching on the south coast, and of a gigantic bird, and the signs of an equally gigantic quadruped having been seen. Only last week we were able to give some news of the indefatigable D'Albertis. Then the Australian colonists are casting longing eyes on the fertile island, and a proposed colonising expedition recently made a considerable stir in this country. All these circumstances have made us anxious to obtain trustworthy information concerning a country of three times the area of England, Wales, and Scotland combined.

Capt. Moresby's work is one of the most important contributions which have been made to our knowledge of the geography of New Guinea. It records in a simple and direct manner the results of four years of thoroughly painstaking and careful work, and, as far as it goes, may be relied on as perfectly trustworthy and accurate. Capt. Moresby does not pretend to give any information as to the natural history of the islands visited, his attention having been directed to their geographical and physical features, their industrial products, and the characteristics of the natives. On all these points valuable and substantial information will be found in the extremely interesting work before us. The time during which the *Basilisk* was at work in Polynesia and New Guinea was between the beginning of 1871 and the end of 1874.

The part of New Guinea to which Capt. Moresby mainly devoted his attention was the coast of that south-eastern projection, about most of which absolutely nothing certain was known, and the islands lying off it. Commencing at the bay shut in by Yule Island, some careful survey work was done, and two considerable rivers explored as far as obstructions would permit. From this point south-eastward the coast was diligently examined, and its main features will be found plotted in the map which accompanies the volume. The greater part of the length of the coast is fringed with reefs, which are the great obstruction to navigation in that part of the world. At several points along the coast more minute explorations were made of various inlets, and one or two other rivers were opened out leading into the interior. Coming to the south-east coast, Capt. Moresby definitely solved the problem as to its shape. The island ends in a wide fork, from which the north coast sweeps in a series of magnificent bays in a north-west direction, the outline of which, to a distance of between three and four hundred miles, Capt. Moresby has had the honour of laying down for the first time. Around the south-east termination of the island are clustered hundreds of beautiful islands ranging in size from a tiny speck up to the three considerable islands which are named after D'Entrecasteaux, and which until Capt. Moresby's visit were vaguely and inaccurately located; indeed it was not certainly known that they were islands at all. The south-eastern prong of the terminating fork is continued in three islands—Hayter, Basilisk, and Moresby—and all the islands of any size seem to support a large population of tractable and intelligent savages. While part of the south coast surveyed by the *Basilisk* is covered with unhealthy mangrove swamp, a large portion of it is a healthy and beautiful coral beach backed by tree-covered hills. Towards the south-east the coast gets

mountainous, a range of mountains running north-west through the centre of the island, having its culmination in Mt. Owen Stanley, 13,205 feet. The three islands mentioned above, as also the D'Entrecasteaux Islands, contain mountains of considerable altitude, and along a great portion of the north coast densely wooded mountains come right down to the coast. The north coast is marked by an almost entire absence of the reefs which are so characteristic of the south coast. Some minute survey work was done among the islands in the south-east, with the result that a passage has been found which will shorten most materially the voyage from Australia to China. Another important service done by Capt. Moresby to navigation was the accurate survey of the channel in Torres Straits.

Captain Moresby landed on many points of the coast surveyed as well as on the islands, and invariably he and his officers and men became the best of friends with the natives. Captain Moresby's skill in managing savages cannot be surpassed. By tact and patience he in almost every instance managed to obtain a cordial welcome from the natives not only of New Guinea, but of the many islands which he visited to the east of Australia. Not in a single instance was it found necessary to take life, and we would recommend all who have to deal with uncivilised people to study Capt. Moresby's tactics. The natives of the part of New Guinea visited Capt. Moresby speaks of as belonging to the Malay type, lighter coloured than the Papuans, and with the characteristic and elaborately done-up long frizzled hair. They are probably a modification of the genuine Papuan, possibly in the direction of the Malay type, though more probably the modification may be the result of circumstances or of mixture with or gradation into a more distinctly Polynesian type. They are well-made, gentle in demeanour, and stand comparatively high in the scale of uncivilised men, both in intelligence and in art. They are evidently comfortable and happy, living in good houses built on piles, and having abundance at hand to supply all their wants. Many of them seemed not to possess the bow—the spear, club, and hatchet being the chief weapons on the south coast. The officers and crew of the *Basilisk* brought away quite a shipload of weapons, utensils, and ornaments, some of them of really exquisite workmanship. The use of the metals is quite unknown among most of the people visited, who in many cases turned up their noses at the hoop-iron with which the ship was so abundantly supplied, and who with difficulty could be made to see the superiority of the iron hatchet. Capt. Moresby gives many valuable notes on these interesting people, which we commend to the notice of ethnologists. One very curious custom is referred to in the south-east, which, when first seen, roused the indignation of those on board the *Basilisk*, but which Capt. Moresby wisely tolerated. A native, followed by a number of others, rushed on board bearing a dog, which, before anyone could interfere, he caught by the legs and dashed out its brains on the deck. This was horribly shocking, but Capt. Moresby rightly surmised that it was meant as a pledge of friendship. Indeed, the poor natives were evidently utterly bewildered when the officer on duty bundled them out of the ship and threw the poor dog's body after them, and it was only on Capt. Moresby's going on shore and professing friendship that they were quieted. Another method of friendly salutation is to squeeze the nose and the navel simultaneously with the fore-finger and thumb of each hand; the natives were quite ecstatic when Capt. Moresby and his men, with excellent tact, returned the grotesque salutation. This pleasant people extend all along the south and north coast visited, the black Papuans differing in many respects from the former, and seemingly quite untractable, not having been met with till about 148° E. on the north coast. Though Capt. Moresby does not profess to be either botanist or zoologist, and unfortunately none of his staff seem to have had the necessary qualifications, still naturalists will be able to glean some information from his notes as to the nature of the flora and fauna to be met with on the coast. We have referred to the signs which a recent expedition saw of some large quadruped living on the island; similar traces were found by the *Basilisk* expedition near the head of Collingwood Bay, the second large bay from the south-east, on the north coast of New Guinea. "Here Lieut. Smith observed the droppings of some large grass-eating animal in a spot where the bushes had been heavily trampled and broken. Our opinion was decided that a rhinoceros had haunted there; and we were much surprised, as the animal has never been believed to exist in New Guinea." This and other secrets of this interesting island cannot surely now remain long unrevealed.

We have referred at length to Capt. Moresby's account of his work in New Guinea, but the first half of the book contains a most interesting account of a cruise among the islands to the east and north-east of Australia, upwards of fifty of which were in this way visited. Almost everywhere was the *Basilisk* welcomed, and Capt. Moresby made excellent use of his opportunities in noticing the characteristics of the islands and the people, and in impressing upon the latter the desire of England to befriend them. In several places sad results were seen, and harrowing stories told of the visits of the Polynesian kidnappers, whose inhuman traffic Capt. Moresby set himself to put down. It seems doubtful whether some of the islands called at by the *Basilisk* have been visited by white men before. The natives were mostly fine-looking people, evidently allied to the gentle inhabitants of Southern New Guinea. On many of the islands white traders and missionaries are settled, in others the natives are still in their pristine and contented state. We assure both the physical geographer and the ethnologist that in this part of Capt. Moresby's work, they will find a very great deal to interest them.

The work altogether must be regarded as one of the most valuable recent contributions to geography. Capt. Moresby possesses many of the qualifications which go to make an explorer of the first rank, and he has the gift of telling his story in clear simple language, indulging in no theories, and filling every page with valuable information. In an Appendix he draws attention to the suitability of New Guinea for colonisation, and urges upon the imperial government, we think with justice, the annexation of it and all the neighbouring islands to the south and south-east. While portions of the island are evidently unsuitable for habitation by white men, a very large proportion of the country

would be found perfectly salubrious and productive in the highest degree. We cannot see the force of some of the arguments with which Capt. Moresby supports his plea for annexation. His strong attachment to the natives and his desire for their welfare we think mislead him as to how this is to be accomplished. If New Guinea is to be colonised by white men, all previous experience teaches us that the natives will inevitably suffer, will be demoralised, and ultimately extinguished. It is inexpressibly sad to think of such a fate overtaking these gentle and altogether superior natives of New Guinea; but how can it be helped, unless it is resolved to put a stop to the increase in the white portion of the world's population. We commend the Appendix to the notice of all interested in Australia, which already is beginning to feel itself overcrowded, and must sooner or later overflow, for, as is well known, the interior is a blank. If this country does not speedily annex New Guinea, some other country, with possibly less regard for the interests of the natives, certainly will. We hope at least that Capt. Moresby's work will be the means of giving a new stimulus to the exploration of this abundantly interesting island. Why don't the governments of the various Australian colonies combine to organise an expedition for its thorough exploration, with the countenance and assistance of the imperial government? With a man like Capt. Moresby at the head of such an expedition, how much might be accomplished.

OUR BOOK SHELF

Sketches of British Insects. A Handbook for Beginners in the Study of Entomology. By the Rev. W. Houghton, M.A., F.L.S. (London: Groombridge and Sons, 1875.)

THIS is an attractive little volume, suitable for a child's prize; it contains much useful and carefully selected information, accompanied by some excellent woodcuts, and six gorgeously coloured plates.[1] Although not wholly free from errors, most of them are happily confined to the chapter on Lepidoptera. It may not be amiss to point them out, as they are likely to mislead, and should be corrected in a subsequent edition.

It is doubtful whether the general reader will comprehend the author's statement that "there are no hermaphrodites in the class" of insects; the frequent occurrence of gynandromorphous specimens in collections being a seeming contradiction to this assertion.

The description of the oviposition of *Chrysopa* (pp. 62, 63) is not accurate. The insect, touching the surface of the plant-stem with her abdomen, draws out a thread of viscous matter, and by not at once excluding the egg attached thereto, gives it time to harden; it is *only by not removing* her body, or depositing the egg too soon, that the upright hair-like thread is produced.

In the chapter on Lepidoptera a number of statements are made, which (however seemingly true to the mere tyro in entomology) are perfectly erroneous: thus it is not true that butterflies ever have less than six legs, although the first pair are, in some families, aborted; butterflies cannot be separated from moths by any distinctions but those which serve to divide their families; for a butterfly has not always a pair of *club-shaped* antennæ, the antennæ of some moths are distinctly clubbed. Although most butterflies carry the wings upright when in repose, the *Ageroniæ*, many of the *Erycinidæ* and *Hesperidæ* settle with the wings flat and extended; some of the *Geometridous* moths on the other hand close them in an upright position over the back. The *Vanessæ* among the butterflies frequently fly by night, and are sometimes taken at sugar;[1] whilst the *Castniidæ*, *Agaristidæ*, *Zygænidæ*, *Ægeriidæ*, many *Sphingidæ* and *Lithosiidæ*, some *Bombycidæ* and *Noctuidæ*, the *Uraniidæ*, some *Geometrina*, *Pyralidina*, *Tortricina*, and *Tineina* all fly by day.

The termination *inæ* should be used for sub-families; therefore it is incorrect to say that "the family *Papilionidæ* consists of two sub-families, the *Papilionidæ* and the *Pieridæ*."

The tails of the *Theclinæ* are not a sufficient distinguishing character, since these appendages occur also in the British *L. bœticus* and its allies.

The Camberwell-beauty has, of late years, been seen on the wing by most entomologists, and the manner in which the squeaking of *Acherontia atropos* is produced has been fully described in a previous volume of NATURE. The wings of the female Vapourer-moth, although very minute, are clearly distinguishable; this insect therefore cannot be said to be "entirely destitute of wings."

The female stag-beetle bites somewhat sharply, but the male has comparatively little power; it is frequently taken to school by mischievous boys to alarm their fellows, but we never knew of a case in which it caused actual pain.

[1] The plates are rather sticky, and consequently the tissue-paper occasionally adheres to them; this is, however, a matter for congratulation, as it subdues the excess of colour.

[1] *Hesperiidæ* have also been taken at light.

The Year Book of Facts in Science and the Arts for 1875. Edited by C. W. Vincent. (London: Ward, Lock, and Tyler, 1876.)

THE present volume is a decided improvement on its predecessor, though it is yet far from being what we hope to see ere long—an annual record of science similar to the excellent American publication edited with so much ability by Mr. Baird. We are glad to observe that this year Mr. Vincent has embraced a wider range in his excerpts, though the newspaper reports of the papers read at the last British Association meeting seem to have been a little too heavily laid under contribution. But then one must remember what a godsend such reports must be to the editor of scientific scraps: two copies of each paper, a pair of scissors, and a gum-bottle, and the thing is done. It would, however, be an injustice to Mr. Vincent to leave our readers under the impression that this book is carelessly edited. Extracts from our own columns, the *Philosophical Magazine*, the *Comptes Rendus*, the *Chemical News*, the *Academy*, and other journals are largely made, and on the whole a wise discrimination and some care have been shown in the selection and arrangement of these scientific jottings. There are, at the same time, some striking omissions which ought hardly to have been passed over. No reference is made to Mr. Crookes's Radiometer and his experiments thereon, beyond a brief report of a discussion on the subject at the British Association. Nor is there any notice of the new system of quadruplex telegraphy, designed by Mr. Winter, nor of the largely increasing use of duplex telegraphy, owing to the valuable modification of that discovery—which really made the system a practical one—devised and carried out some time ago by Mr. W. H. Preece. We commend the editor to the columns of the *Telegraphic Journal* for information on these points. There are also other omissions of recent experimental researches, but as we have already said, this volume is not without its merits, and doubtless many will be glad to make use of the quantity of broken-up information it conveniently conveys. We presume Prof. Osborne, on p. 72, means Prof. Osborne-Reynolds.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Professor von Siebold and the Freshwater Fishes of England

THE object of the present letter is to appeal to naturalists throughout the British islands to assist Prof. von Siebold—the eminent zoologist of Munich—in his studies of the freshwater fishes of Europe. Prof. Siebold is preparing a new edition of his well-known work on that subject, and is exceedingly anxious to obtain specimens of some of our British freshwater fishes to compare with the specimens which he has collected from all parts of Europe. In spite of various attempts, he has, I am very sorry to have to say, failed to obtain specimens from English naturalists. I am sure that this can be only owing to the fact that he has not been able to make his wants known directly to those who could help him. I have not myself been able to do much in supplying the specimens of which he forwarded to me a list, but from the Thames at Oxford have sent him Dace, Bleak, Pope, Miller's Thumb, and Sticklebacks. The list to which I refer included the Graining and the Azurine fishes which have been obtained in or near Knowsley Park; and I have received a kind assurance from Lord Derby that efforts shall be made to procure specimens for Prof. Siebold. Specimens of these and of the Powan, the Pollan, the Gwyniad, and the Vendayce, are the chief desiderata which I am anxious to obtain for Prof. Siebold; his list also includes the Sharp-nosed and the Broad-nosed Eel.

If any naturalist who possesses specimens of these fish which he can spare for the purposes of scientific investigation, or who can by reason of local opportunity obtain such specimens, will forward them to me at University College, London, preserved in spirit, I will transmit them to Prof. Siebold, taking care that he shall know to whom he is indebted in each case.

A more difficult task, I am afraid, is that of procuring specimens of the Brine Shrimp, *Artemia salina*. Prof. Siebold has made an extensive study of specimens of Artemia and allied Branchiopoda from various European localities, and is anxious to compare English specimens with those from other localities. He wishes especially to obtain "gatherings" of these Crustacea in order to determine the absence, presence, and relative abundance of the male sex in different localities. Specimens from Lymington or from Guernsey would be very welcome.

I hope that through the columns of NATURE I may succeed in reaching those naturalists who, I am sure, are not few in number, who will be willing to contribute material for the valuable researches which Prof. Siebold has so long been carrying on.

Seasonal Flower Distribution and the Radiometer Vagaries

ALTHOUGH apparently so dissimilar, there is an intimate connection between the seasonal order of colour in flowers and the seeming erratic behaviour of certain radiometers.

Whatever be the cause of the mechanical action of light which is now exciting so much attention, the kind of light remaining the same, the experiments show that different surfaces produce dissimilar effects, the results with pith discs applying to pith only and being different from those obtained with mica, which strictly apply to mica alone. This is due in all probability to the difference in inter-molecular conditions presented by the two substances. When these conditions are thoroughly understood and a proper margin allowed for experimental errors, the observations which seem now at variance will most likely be reconciled. To acquire the needed knowledge, it is my humble opinion that some modification of the present method will be required, because many of the comparative experiments which have been tried hitherto in the domain of radiant light and heat are open to the objection that heterogeneous bodies having been dealt with, a difference of chemical constitution has been introduced for which no allowance could be made. To obviate this in the present instance, and ascertain the result of such differences, would it not be well to employ the following typical mode of procedure:—

In preparing the radiometer, let the discs be dipped into melted sulphur, or other convenient colour-changing body, and the completed apparatus inclosed in a jacket for the convenience of raising the temperature. A series of observations made at the normal temperature, when compared with a like series made at a high temperature, would doubtless reveal many interesting facts. There are many difficulties in the way which would take much experiment to overcome.

Now turn we to the flowers. The former question seems to depend probably upon the reflection of light, and the latter on absorption, the one being complementary to the other. I would here call the attention of your readers to the behaviour of inorganic coloured bodies when heated and to the laws of colour-change given in NATURE (vol. xiii. p. 298). There is here such an identity of relations as nearly to preclude the possibility of its being a mere coincidence. I shall speak more particularly of this in another note in a few days.

In reply to Mr. Rogers' query (p. 326), it may be remarked that *absorbed light* seems to be the active agent in vital work, *e.g.*, it is the light absorbed by the retina which, as motion of some kind, is transmitted along the optic nerve. This being the case, it would seem highly probable that to exclude from a flower such light as it reflects would not affect it at all, although of course the only sure answer to such a query is experiment.

D-line Spectra

WITH reference to Prof. Stokes's courteous but rather theoretical explanation in NATURE, vol. xiii. page 247 (which I have been prevented from acknowledging before), I would ask him or yourself for a practical explanation of the following simple experiment:—

1. If platinum wire be reddened from a constant source of heat, as that applied to it by means of a blowpipe and a candle, we find the D-line spectra indefinitely produced until incandescence takes place by *additional* heat, or, in other words, that their permanency is in direct proportion to the *bulk* of the wire used, and in inverse proportion to the amount of heat applied. We can therefore, by using a *thick* platinum wire and the ordinary flame of a blowpipe, produce D-line spectra as long as we like, or as long as the fuel lasts.

2. Now if this D-line producing flame be due to sodium, its action for a long period upon a reagent so sensitive to sodium as is *Boric Acid*, ought to give a reaction by which the presence of that alkali would be detected. Thus, if a pin's head speck of pure cobalt oxide be heated by a blowpipe in a bead of pure boric acid, it forms within it a *black ball* which the minutest trace of any *sodium* salt partially dissipates, causing a *pink* suffusion round the ball.

3. A boric acid bead fused upon the ring of a thin or ordinary platinum wire, which has previously been made incandescent by a blowpipe flame, *i.e.*, from which the D-line producing property has been previously removed, is clear, colourless, and refractive as a diamond; but if the same boric acid be fused upon a *thick* platinum wire with the same degree of heat, the bead is *opaline* and *almost opaque*; and this phenomenon seems evidently and only referable to the above-mentioned permanency of the D-line spectra produced in the latter case.

4. To settle this point, however, let us fuse a clear colourless bead of boric acid on an ordinary platinum wire, and screw that in a geometrical pen, along with, but a little *behind* (that is, *away* from the source of heat) a *thick* platinum wire, so that the D-line producing flame from the thick, hot wire, impinges constantly and for some time upon the clear boric acid bead; we find opacity produced as in the former case. Now, supposing sodium to be in this case, the producer of the D-line spectra, we ought to have, in the opalised boric acid, a tangible result of the effect of applying to it (according to Prof. Stokes) "free sodium," but, on heating in it, as before, a speck of cobalt oxide, there is *no* dissipation of any part of the resulting ball, nor the least pink suffusion, but, on the contrary, a reaction, decided indeed, but *almost exactly* the opposite of that caused by adding sodium to the bead in any proportion.

5. Let us now screw a platinum wire ring containing a boric acid bead with a cobalt-borate ball inside, into a geometrical pen behind another platinum ring containing a bead of some soda salt, and heat both together with a blowpipe, so that the orange flame from the latter impinges upon the former. Instead of opalescence, similar to that caused by the orange flame from the thick platinum (4), we find the viscid boric acid made *more*

fluid and clear, the cobalt borate ball partly dissipated, and, on cooling, the surface of the bead presenting a pink appearance, evidently caused by projected particles of soda, volatilised *per se*.

6. It would thus seem that the blowpipe is even a more delicate analytical weapon than the spectroscope, for it distinguishes between two flames exhibiting D-line spectra only, which spectrum analysis does not.

The Screw-Propeller in Nature

Now that the question of the best form of the screw as a propeller has become of such importance it is interesting to note what Nature has done in this direction.

The seed of the ash (*Fraxinus excelsior*) is provided with a wing very delicately twisted, and, when the seed falls, the action of the air upon this screw-like wing causes it to revolve rapidly. The result is that the seed is kept suspended in the air for a comparatively long time, and is wafted by the slightest breeze to a considerable distance from the parent tree. I do not know that this peculiarity is referred to in any botanical work, but it very beautifully fulfils the object which characterises more completely the lighter-winged seeds, viz., the dispersion of the seed beyond the limits of the plant or tree which bears it.

I am not by any means sure that the screw on the ash seed will not *by its own action*, independently of any wind, work itself away, in its fall, from the perpendicular line. But, when the wind blows strongly—and it takes a strong wind to blow the seeds off at all—their range is very extensive.

The seeds hang stubbornly to the tree through the winter months, reserving themselves for the March gales, of which the wind-fertilising plants avail themselves so largely.

I should much like to know if any of your readers have observed this screw and studied its pitch, and it would be very remarkable should it prove that the pitch of this natural screw is the one which will give the most power to the propeller of a steamer.

The seeds of the maple and the sycamore have somewhat similar appendages, but the screw is, in neither case, so marked. If anyone, at this season, will throw up a stick at the seed clusters of ash, maple, or sycamore, he will find the seeds come fluttering to the ground like a cloud of butterflies and alighting quite as softly on the ground.

Feb. 15 ALFRED GEORGE RENSHAW

The Migration of Species

In NATURE, vol. xii. p. 86, I read a communication signed "W. L. Distant," in which the writer states that sea-going ships were frequently visited by both birds and insects.

In confirmation of this fact, I can mention from my own observation two instances of birds visiting ships in which I was making the homeward voyage from the West Indies, and one instance on a voyage to New Zealand, in which the visitor was a butterfly.

In the first case, the ship being off the Spanish coast, but not in sight of land, a very handsome bird came on board. It was a species of dove, blue being the principal colour, with darker markings. Some of the seamen called it a Spanish dove. It was caged and taken home by one of the passengers.

In the second case, being in the neighbourhood of Bermuda, a large flight of a species of swallow settled on the vessel. These poor birds were in a very exhausted condition, and numbers of them were captured by a large cat belonging to the ship. The survivors continued their passage at daybreak next morning.

In the year 186—, on a voyage to New Zealand, we were one morning visited by a butterfly, there being at the time a light breeze blowing. My sons made great efforts to capture this interesting stranger, but unfortunately without success, as it fluttered overboard, and was soon lost to sight in the hollows of the waves. They, however, got sufficiently near to ascertain it to be a true butterfly. The colour consisted of various shades of rich orange brown, and the margins of the wings were deeply indented.

I made careful inquiries of the officers of the ship as to the proximity of land, and was informed that the nearest was the rock of St. Paul's, then fully two hundred miles distant.

The Three Kingdoms of Nature

SOME children were playing at a game called "The Kingdoms," which consists in the mention of various substances, and asking if they belong to the animal, vegetable, or mineral kingdoms. One little girl mentioned "water," and the company were puzzled as to which kingdom it should be assigned. Is there a sub-aërial or gaseous kingdom? Will you kindly enlighten the members of our NURSERY?

March 4

OUR ASTRONOMICAL COLUMN

THE VARIABLE STAR, β PERSEI (ALGOL).—Herr Julius Schmidt, Director of the Observatory at Athens, publishes in the *Astronomische Nachrichten* the results of observations on the times of minima of this variable star, extending from August 1846 to November 1875. The epochs are given in Paris mean time with correction for the light-equation. The probable error of a single determination of the time of minimum from 183 observations by Schmidt is ± 8·0 minutes; fifty observations of Argelander gave a probable error of ± 6·0 minutes, and fifty-five observations of Schönfeld, one of ± 4·6 minutes, showing by a mean of the 288 observations a probable error of ± 7·0 minutes. The period assumed by Schmidt in the discussion of his Algol observations between 1840–1875 is 2d. 20h. 48m. 53·6s.

Some interesting details respecting this star are found in Schönfeld's "Der lichtwandel des Sterns Algol im Perseus" (Mannheim, 1870). His comparison stars and their relative assumed brightnesses were :—

Star.	Brightness.
ν Persei	0·9 in grades.
α Trianguli	3·5 ,,
δ Persei	7·8 ,,
β Trianguli	9·1 ,,
γ Persei	10·9 ,,
ϵ Persei	12·8 ,,
β Arietis	16·7 ,,
ι Aurigæ	17·3 ,,
γ Andromedæ	23·4 ,,

The following, extracted from the more extensive table given by Schönfeld in his treatise, will indicate the law of variation as derived from the light curve :—

Distance from Minimum. h. m.	Brightness. Before.	After.
4 30	20·7	20·8
4 0	20·2	20·2
3 30	19·6	19·2
3 0	18·7	17·7
2 30	17·4	15·8
2 0	15·3	13·2
1 30	12·1	9·8
1 0	8·5	7·6
0 30	6·3	6·2
0 0	5·6	5·6

The most probable period over which the variation extends is $9\frac{1}{4}$ hours, and the minimum lies very nearly in the middle of the same. The most perceptible diminution of brightness occurs 1h. 26m. before the minimum, when the star is somewhat fainter than the mean of γ and ϵ Persei, and the most perceptible augmentation when the star arrives at nearly the same degree of brightness, but 1h. 47m. after minimum. In this phase it is hardly fainter than the mean of δ Persei and α Trianguli. Schönfeld states that to his eye the variation of Algol is included between the magnitudes 2·2 and 3·7; he considers γ Andromedæ an average star of the second magnitude, δ Persei 3·5, α Trianguli about 3·1, and ν Persei 4·1.

For elements of Algol we may adopt at present the following, derived from Schönfeld's last catalogue. First minimum of 1876 .. January 2·23233 Greenwich mean time; period 2·867288.

CONJUNCTION OF JUPITER AND β SCORPII.—Mr. J. Birmingham, Millbrook, Tuam, writes as follows with reference to the near approach of Jupiter to the bright star β Scorpii on the morning of Feb. 28.—"The weather prevented any observation until 19h. 25m. Greenwich M.T., when the western limb of Jupiter had nearly, but scarcely quite, reached the R.A. of the star. The micrometer-wire through the star then just grazed the northern edge of the planet, and so closely that it could not be said for certain that there had not been actual contact. Clouds coming on again soon put an end to the observation." Allusion was lately made to the above phenomenon in this column.

NOTE ON BIELA'S COMET.—It will be remembered that when, on the appearance of Biela's Comet in 1805, the similarity of elements to those of the comet of 1772 had been remarked, it was pointed out by Gauss that the differences between the orbits, particularly the diminution of the inclination, could not be accounted for except on the supposition that in the interval the comet had undergone perturbations from one of the larger planets, and the necessary proximity could only have been consistent with the assumption that several revolutions had been performed in the interval between 1772 and 1805, as on the next observation of the comet in the spring of 1826 was proved to have been the case.

If we adopt the elements for 1772 assigned by the late Prof. Hubbard of Washington in his masterly investigation on the motion of this comet, we shall find the following distances from the orbit of the planet Jupiter :—

True Anomaly.	Radius vector.	Distance.
+ 156° 0′	5·029	0·316
157 30	5·143	0·281
158 0	5·180	0·283
+ 160 0	5·327	0·344

A true anomaly of 157° 30′ corresponds to 645·5 days after a perihelion passage, and the comet would arrive at this point of its orbit, which may be taken as that of nearest proximity to the orbit of Jupiter about 1794·21, while the planet would be in the same longitude about 1794·43, and it thus appears that it was in the spring of the year 1794 that the very material changes in the elements of the comet's orbit were caused by the attraction of Jupiter. Another near approach of the two bodies would appear to have taken place towards the end of the year 1746.

THE NEW GERMAN SCIENTIFIC EXPEDITION TO THE OBI

THE Expedition to Northern Siberia, fitted out by the "Verein für die Deutsche Nordpolarfahrt in Bremen"—the same Society which sent out the Second German North Polar Expedition, and published the excellent account of its results—left Bremen last week. The attention of the Council of the Society having been called to the immense unexplored area between the Jenisei and the Obi, it was resolved, as there were not sufficient funds for a naval expedition this year, to send out a small zoological and ethnographical expedition overland to the Obi, which appeared to be less known than the Jenisei. In this they received the warm support of the highest scientific authorities at St. Petersburg who were asked for advice on the subject. Dr. Otto Finsch, Director of the Zoological Museum at Bremen, was appointed leader of the expedition, and Dr. Brehm, the well-known author of "Das Thierleben" and many other natural history works was selected to accompany him. They were joined by Count Walburg-Zeil-Trauchburg of Stuttgardt, who made an expedition to Spitzbergen in 1870 at his own expense, and who is well acquainted with physics and is a good botanist. Professor Oscar Schmidt of Strasburg, who had likewise intended to go, was unavoidably prevented at the last moment. The route selected is by St. Petersburg and Moscow to Nishni, and thence in sledges viâ Kasan, Perm, Ekaterinenburg and Omsk to Semipalatinsk. Thence a detour will be made, if possible, into the Altai. From Ekaterinenburg they will go to Barnaul and down the Obi to the embouchure of this river. They will return to Germany in the autumn—certainly not without a rich harvest of results.

UNIVERSITY REFORM

(Communicated.)

THE speech of Lord Salisbury on introducing a bill to reform the University of Oxford, inaugurates a fresh epoch in the history of University reform. The speech nominally referred to Oxford only, but the principles enunciated in it apply equally to both Universities. The defects of the Oxford system, pointed out with such clearness by Lord Salisbury, are also the defects of the Cambridge system, and the remedies to be applied, must, in their broader features, be the same for the two Universities.

Lord Salisbury lays it down as the cardinal point in his scheme of reform that, till the requirements of the University for teaching and research are satisfied, no portion of the funds of the colleges ought to be employed for endowing idle fellowships.

"I do not know," he says, "that what is available from the whole of the idle fellowships will be required for University purposes, and I do not venture to lay down the principle that no fellowship should exist which would give the holder no educational work, and which should last for a few years. It may be wise to maintain a few of these, limiting the holding of them to a certain number of years, but I do venture to lay down that all the University wants in the shape of museums, libraries, lecture-rooms, and the proper payment of teachers, should be provided for before the subject of furnishing incomes to men who do nothing can be entertained."

The enunciation of such views as these by a Conservative Minister must be hailed by genuine University reformers as a most reassuring sign of the progress of public opinion. Up to the present time such principles as those contained in Lord Salisbury's speech have only been whispered in secret by a few men who have been generally regarded as extreme and unpractical ; but it is to be hoped that for the future these principles will form the starting-point of University reform. It is to be regretted that they have not been more distinctly embodied in the Bill presented to Parliament. The indefiniteness of the plan of reform there laid down, and the powers of resistance secured to individual colleges, seriously detract from its efficiency. We trust that these points will be altered in Committee ; otherwise everything will depend on the wisdom, union, and determination of the Commissioners.

Lord Salisbury alluded to the more pressing wants of the University of Oxford, which include a new library, museum, schools, and other permanent structures ; and states that for these alone an immediate outlay of 210,000*l*. is required. In addition to this sum a large yearly income is needed to bring up the staff of University teachers to a suitable standard both in numbers and efficiency. Large as are the wants of Oxford, we believe that those of Cambridge are also very large both as regards permanent buildings and the professoriate. This is not only shown by the report of the Buildings Syndicate of the University of Cambridge, but also by the recent appointment of a Studies Syndicate, which indicates that the present staff of teachers is generally considered inadequate. The above facts are in themselves sufficient to demonstrate that, if the principles laid down by Lord Salisbury are firmly carried out by the Commissioners it will

be necessary for them to abolish in a nearly complete manner the existing idle fellowships.

In fact the term "Fellow" will cease to be the name for a successful candidate in an examination, who, as a reward for his success, receives for a longer or shorter period a considerable income, and will become the title of one engaged in University work.

It must not, however, be lost sight of that the abolition of idle fellowships is only valuable as a means to an end—that end being the increased efficiency of the teaching and research in the Universities. On this account it becomes important to follow out the further changes which will be entailed by the abolition of idle fellowships.

On the abolition of these fellowships, all the colleges will be in possession of a large income entirely available for University purposes. A considerable part of this will no doubt be at once employed for the buildings and other permanent structures needed by the Universities, and will be handed over to the Universities either in the form of a yearly tax or a share of the college property. Of these two methods of contribution the former appears on the whole to be attended with the fewest inconveniences, and will have the further advantage of supplying at once an available income to the University.

On the most extravagant estimate it seems clear that, after all the requirements of the University for permanent buildings, &c., have been satisfied, the available revenues of the colleges will by no means be exhausted, but a considerable sum will still be left to meet the urgent need of fresh Fellows to carry on the work of the University.

Ought the money intended for the payment of these Fellows to be handed over to the University, or left in the hands of the colleges? Although some advantages might accrue from handing over the money directly to the University, yet the proposal cannot be entertained. No Conservative Government could thus despoil the colleges. The opposition would be too great and not improbably the whole scheme of reform might be ruined. If it is admitted that the money is to remain in the hands of the colleges, a further question arises as to the system under which the new Fellows are to be elected.

Is their election to be carried on by the colleges on the old system, or to be more or less directly under the control of the University? We believe that the value of the proposed reforms depends greatly upon the answer given to these questions.

In dealing with them in a practical way it is neither possible nor desirable to overlook the fact that a collegiate system of teaching exists. Were it proposed, while still leaving the money in the hands of the colleges, to remove the election of the Fellows completely from their control, they would feel greatly aggrieved and would offer the strongest opposition to the scheme. It certainly could not be looked on as otherwise than a hardship for the colleges, that they should have no voice in the election of the men who were to form their governing body.

It must not, however, be overlooked that so long as Fellows are elected on the present system, a great increase of efficiency in the teaching staff of the University cannot be anticipated.

The causes which render the present system unsatisfactory are for the most part easily detected. In the first place Fellows are not elected for their efficiency in teaching or in research, but on account of their success in an examination, a very unsatisfactory test either of their powers of research or their powers of teaching.

In the second place, the standard requisite to obtain a fellowship, especially at Cambridge, is very different in the various colleges. In some of the smaller colleges the standard is very low, yet were the present system to be continued, these colleges would go on appointing Fellows totally incompetent for their University position.

In the third place, the nature of the colleges as closed corporations causes it frequently to happen that, after a man has been elected to a fellowship and continues to reside, he is appointed to a lectureship in spite of evident incompetency. In addition to these inherent faults in the existing mode of election to fellowship, the present system labours under great defects owing to the absence of centralisation. So great are these defects, that both Universities have recognised, and to a certain extent attempted to cope with them. Cambridge has done so by starting what is known as the "intercollegiate system of lecture;" a system which consists in the combination of the greater number of the colleges for the purpose of having common lectures open to the students of all the combining colleges. Oxford possesses a somewhat similar system, including several combinations of three or more colleges with the same objects as the one combination at Cambridge.

We cannot enter into the details of these systems, but confine ourselves to pointing out that they are generally recognised as very imperfect substitutes for a completely centralised system. They contain no sufficient guarantee for the efficiency of the teachers employed, and in the case of subjects where the students are few, the very existence of these systems interferes with the appointment of fresh lecturers, however incompetent the existing lecturers may be; and lastly they afford no help whatever to research.

The past action of the Universities themselves, as well as other considerations, indicate that the present system of election to fellowships ought to be abandoned, and a system involving greater centralisation substituted for it.

Though Lord Salisbury does not distinctly state that he regards this centralisation as necessary, yet the general tenor of his speech clearly indicates that he does so; and the very argument he has used against permitting the colleges separately to reform themselves, applies equally against their separate action in the election of Fellows.

To meet the requirements of the University in the election of Fellows, it is necessary to devise some system in which a central board, directing and influencing the elections, shall work in concert with the colleges in whom the actual election must be vested.

The function of the central board ought not only to be the indication of the men to fill the fellowships, but also the settlement of the branches of study in which teaching or research is required. In the election of Fellows by a college, no preference ought to be shown to a member of the college, and the lectures of the Fellows ought to be equally open to all the students of the University. In such subjects as natural science, rooms ought to be assigned to the Fellows in the University buildings.

Whatever system of election of Fellows may ultimately be found advisable, the colleges will necessarily be left completely free to elect their Tutors, Bursars, Deans, and other officers, and the election of a certain number of Fellows for college teaching ought to be left in their hands.

The partial inefficiency of the present staff of University professors will probably be urged as an argument against the centralisation of teaching in the University. This inefficiency, so far as it exists, has mainly arisen from its not being possible for men who have obtained a University post to rise in their profession; and we believe that by instituting a series of grades, the highest of which shall only be held by distinguished men, it will be possible to supply the stimulus as necessary for efficiency in a University career as in all other professions.

The efficiency of the Professoriate in the German Universities appears to be mainly due to the existence of this stimulus, and we may therefore hope that the presence of this alone is necessary in order to render the professors in the English Universities as efficient as those in the German ones. Promotion ought of course to be granted for research as fully at least as for successful

teaching, and a much-needed stimulus thereby given to learning in the Universities.

The remarks of Lord Salisbury on the question of research are quite as liberal as those on the questions of general education of the University. "The only point," he says, "in the connection to which I wish to call attention is that referring to research. We are of opinion that the mere duty of communicating knowledge to others does not fulfil all the functions of a University, and that the best Universities in former times have been those in which the instructors, in addition to imparting learning, were engaged in adding new stores to the already acquired accumulation of knowledge."

How best can research be combined with teaching? It will probably be found advisable to relieve from all teaching some of the professors who belong to the highest grade, and who have shown their capability for research; but we do not believe that this principle can with any advantage be generally adopted in the case of young and untried men. It would appear to be far safer to give opportunities of research by not demanding too much teaching work. With a large staff of lecturers it would not be necessary to demand from each more than two terms' teaching in the year. With only two terms' work and the remainder of the year free, ample time would be given for a teacher, not only to keep up with the progress of his subject, but also himself to advance it; but this point might be left for further consideration and experience.

The research we are anxious for is not confined to the natural sciences, but embraces all branches of learning, and we cannot better explain our view in this matter than by again quoting a passage from Lord Salisbury's speech. "What I am particularly anxious for," he says, "is that all branches of culture should have equal encouragement, and should be regarded not as rivals but as allies in the great and difficult task of cultivating and developing the human mind."

SCIENCE AND ART IN IRELAND

THE Royal Dublin Society held a special meeting on Thursday, March 2, to consider the Report of the Council on Lord Sandon's letter. In the absence of his Grace the Duke of Leinster, the President of the Society, the chair was taken by Sir George Hodson, Bart., one of the Vice-Presidents. Dr. Steele read the Report of Council, which concluded with a recommendation that the Society should sanction the Council's sending a deputation to London to press the following points upon her Majesty's Government:—

1. An assurance that the library, and the collections in the museums, shall be maintained in Dublin for the use of the public.

2. That ample accommodation shall be secured for the members of the Society for the purposes of their meetings, for their reading rooms, and for their officers; the whole being maintained for the Society, and under its own control.

3. That a suitable apartment as a reading room in connection with the library shall be provided for the exclusive use of the members of the Society.

4. That the members shall have the privilege, under reasonable restrictions and conditions, of borrowing books out of the library.

5. That the Agricultural Department shall be compensated by an equivalent for any space of which it may be deprived.

6. That the laboratory, with the services of an analyst, shall be preserved as heretofore for the purposes of the Society.

7. That the services of the present officers of the Society shall be retained; or the salaries and emoluments which they now enjoy secured to them.

8. That, as heretofore, an adequate staff shall be maintained for the purposes of the Society, or an equivalent grant to enable it to provide itself with the same.

9. That the members shall have free access to the new Institution at all times that such s open (whether by payment or otherwise) to the public.

That as some equivalent for the property surrendered, and as a compensation for a possible falling off in the income of the Society, an annual sum be granted to enable it to continue its several works of utility.

Mr. Ferguson moved a resolution in the following terms: "By reason of the very recent date of Lord Sandon's letter (Feb. 9, 1876) relative to the establishing in Dublin of a 'Science and Art Museum,' and the consequent short period the Council of the Society have had to make the Report thereon as this day laid before the Society, it is desirable that the consideration of the Council's Report be now adjourned till this day four weeks, for the purpose of enabling the Council to lay before the members of the Society such necessary information as will enable due and proper action to be taken on the several matters therein." This resolution was at once seconded by Dr. O'Donovan, and the necessity of adjourning was urged by several members to whom the leading facts in reference to the Society's relation to the Government, as stated in the Council's Report, appeared quite new. Dr. E. P. Wright said that the mover and seconder of the resolution asked for more light; to him it appeared as if the light they already had had dazzled them. Let the terms of the minute of the Science and Art Department of Sept. 21, 1865, be remembered, and how could the Society indulge in the illusion that the so-called Departments of the Society belonged to it otherwise than as in trust for the public? As to representing that the Government were not fully aware of the position of affairs, was it not a fact that the Chancellor of the Exchequer, Lord Sandon, and Mr. W. H. Smith had within the last few months personally inspected all the arrangements of the Society for themselves? and did anyone present doubt that Sir M. H. Beach had not a perfect knowledge of the Society's wants and merits? and then there had been a Parliamentary inquiry in 1864 and a Royal Commission in 1868. Why then waste time in asking for more information? Lord Sandon's letter was clear and explicit. Why not boldly face the inevitable, and see in the proposed scheme a means of having in Dublin what all desired, a National Library and a Museum of Science and Art? Several of the points asked by the Council it seemed probable would be yielded by the Government; but he appealed to those who had the true interests of their country at heart to support and co-operate with the Government in this matter, and not to treat them as Greeks, though bringing gifts. As the feeling of the meeting seemed to be in favour of having the Council's Report *in extenso* before them, he would move as an amendment: "That Lord Sandon's letter and the Report of the Council just read be printed and circulated among the members; and that this meeting do adjourn until this day fortnight—then to consider the same." This amendment was seconded by Lord Powerscourt, but on being put was negatived, whereon the original resolution was put from the chair and declared duly carried. It was further resolved that the Council should send a deputation to London to obtain such additional information as they could as to the intentions of the Government.

At a special meeting of the Royal Irish Academy, held on Monday last, the following amendments were adopted by a large majority:—

1. That the Royal Irish Academy being desirous of co-operating with her Majesty's Government in the measures necessary for the establishment of a National Science and Art Museum in Dublin, provided that the independence and usefulness of the Academy be not injuriously affected by such measures, is willing to consent to the

transfer of its antiquarian collections commonly known as its Museum, to the Government upon the conditions—

a. That the arrangement of the Museum, as well as the purchase of additions, shall continue to be conducted by the Academy; and that adequate provision shall be made for the continued acquisition of Irish antiquities which may hereafter be discovered or offered for sale.

b. That the Museum of the Academy, together with such other Irish antiquities as may be added to it, shall be for ever kept apart from other collections, and be permanently maintained as a Museum of our National Antiquities, no portion of its contents being ever removed from the City of Dublin, unless by permission given under the seal of the Academy.

c. That the Academy shall be accountable, as at present, to her Majesty's Treasury, through the Irish Government, for all sums voted by Parliament, and shall not be subject, in the conduct of its affairs or the expenditure of its grants, to any control on the part of the Science and Art Department, or any of its officers.

2. That, considering the position which the Academy has long held, and will continue to hold, as the first scientific, literary, and antiquarian Society of the country, the proportional representation proposed to be given to it on the Board of Visitors (sect. 12 of Lord Sandon's letter), is altogether inadequate; and the Academy further think that no paid official of the Science and Art Department should be eligible to act as a representative on the Board.

3. That there should be provided in the yearly estimates, as laid before Parliament, instead of the several sums now annually voted, a sum at least equal to what is at present voted, to enable the Academy to discharge more completely its functions as a scientific, literary, and antiquarian body, by making grants in aid of original research, by publishing the results of such research, by maintaining a library specially adapted to assist learned investigation, and by editing and printing ancient Irish texts, &c.

SCIENTIFIC INSTRUCTION AND THE ADVANCEMENT OF SCIENCE.

ON Wednesday and Thursday last week two separate deputations from the Council of the British Association waited respectively on Mr. Cross and the Lord President of the Council, the Duke of Richmond and Gordon, both introduced by Dr. Lyon Playfair, and headed by the president of the Association, Sir John Hawkshaw. The object of the deputations was to induce the Government to adopt certain recommendations of the Royal Commission on Scientific Instruction and the Advancement of Science.

Dr. Playfair said there were three points in the Reports of the Science Commission to which they desire to direct attention—namely, the recommendations as (1) the study of science in elementary and endowed schools, (2) the endowment of research, (3) the administration by a Minister of Science and Art.

Sir John Hawkshaw said that the matters which they that day desired to mention were chiefly treated in the Fifth and Eighth Reports. He read a memorandum on these points approved by those he represented. This document set forth that the Government possessed, through the elementary schools and through the authorities charged with framing schemes for endowed schools, the machinery for insuring scientific teaching. The public schools will follow the Universities; the Universities in England and Scotland are about to be the subjects of inquiry by Commissions, and science ought to be adequately represented on these Commissions. University College and King's College, London, Owens College, Manchester, and Trinity, Dublin, would require special consideration, and if further pecuniary assistance were granted them by Government, guarantees should be taken for the further encouragement of scientific teaching. Direct endowments of research must be approached with caution. There would be no objection to the course of liberally endowing professorships in the several Universities, combining the duty of original research with a moderate amount of teaching to be attached to the professorship; an extension of the principle involved in the grant to the Royal Society might be advantageously resorted to, and the grant might be gradually increased. The Lord President of the Council was practically entrusted with the functions of a Minister of Education, responsible to Parliament; and it therefore seemed to follow that he should be made the responsible administrative head of the business connected with scientific institutions which receive their support from public grants, with the allocation of funds for scientific purposes, as well as of the business relating to the promotion of scientific instruction, as these matters all form an essential part of public education in science. Sir John Hawkshaw would only add to the document that it would be of great advantage if the State would establish, say, a laboratory for chemical science, and an observatory for physical investigations.

Prof. A. W. Williamson, Prof. Roscoe, Mr. Spottiswoode, Dr. De La Rue, and others spoke in support of the deputation's object, with which Mr. Cross said he sympathised very much indeed.

The Duke of Richmond and Gordon said the Government were well aware of the great importance of scientific education. With regard to the Reports of the Science Commission, he thought Lord Salisbury was now acting upon the Third Report, in respect to Oxford and Cambridge. It seemed to him that the endowment of professorships had not been altogether satisfactory so far as it had been tried. With regard to the Government grant to the Royal Society, that was a grant, not an endowment for those who work, but, as he understood it, a provision of apparatus. The sum of money was so expended. It was not an endowment of research. With regard to establishing physical observatories, the Government had taken action in the work connected with astronomical physics which Mr. Norman Lockyer was now carrying on, or beginning to carry on at South Kensington. With regard to the laboratories for chemistry and physics which Mr. De La Rue alluded to, it seemed to him they could not very well do more in that direction till they had the report of the Commission which was to inquire into the Universities' scheme proposed by Lord Salisbury. He concluded by assuring the deputation that the Government were quite alive to the great importance of the subject.

PHYSICAL SCIENCE IN SCHOOLS

I CONFESS I did not understand Dr. Watts's letter quite as Prof. Roscoe has done. But that is of little importance. Prof. Roscoe has opened wider questions as regards the position of Physical Science at Schools, and I should be glad of the opportunity, if you can spare me the space, of writing a little more at length on this matter, and, if possible, of thereby arriving at a distinct understanding what it is that the thorough-going advocates of science, like Prof. Roscoe, want. His letter is a good hearty grumble at things in general, and a good grumble from him wakes people up, and does us all good; but we want to know what specific changes he wants, and who is to make them. "Regulations" and "Examinations" and the "position accorded to science in schools," and the "discouragement to the teaching of science," want of "efficient means of teaching science," "difficulty of obtaining masters," are all in turn mentioned as obstacles. Some of these arise from one cause, some from another, and before any improvement can be effected, we must analyse the position of science at schools, see what

the circumstances are which affect it, and understand where pressure can effectively be brought to bear.

The position of science at schools is dependent on—

1. The Public Schools' Commission.
2. The Statutes and Regulations of each School; *i.e.*, the Governing Bodies.
3. The Indirect Influence of the Universities and other Examining Bodies.
4. Head-Masters.
5. Parents.

1. The Public Schools' Commission enforce the teaching of science by requiring (Reg. 3) that "In any examination of a boy (not being one of the senior boys) in the school, or in any report of a general examination, the proportion of marks to be assigned to Natural Science shall be not less than one-tenth nor more than one-fourth, as the Governing Body shall think fit." Also that (Reg. 6) "There shall be one Mathematical Master, at the least, for every 100 boys in the school, and one Science Master, at the least, for every 200 boys learning Natural Science in the school." Also that (Reg. 7) "Every boy shall learn Natural Science continuously from his entrance into the upper middle form, Div. II., until he become one of the senior boys in the school." Further, that (Reg. 8) Senior boys may pursue special subjects of study and discontinue other subjects for that purpose: and that (Reg. 11) "Any boy in the school who may evince an aptitude for Natural Science shall have facilities for that study." Also (Reg. 10), "Any boy entering the school shall have the opportunity of showing acquaintance with Botany, Physical Geography, or some other branch of Natural Science."

It is evident that the all-important question here is, who are senior boys? Regulation 5 says "the Governing Body shall from time to time determine the point in the school list above which the boys shall be reckoned as senior boys for the purposes of these regulations."

These regulations are dated Aug. 4, 1874.

I do not think any reasonable fault can be found with these regulations from Prof. Roscoe's point of view, unless he finds fault with Regulation 7, which does not give natural science equality "as regards range," with classics and mathematics. To this I shall recur again.

2. The Statutes of Rugby School order that three Major Exhibitioners shall each year be elected—to pursue their studies elsewhere—for general proficiency in the studies of the school; and that four Minor Exhibitioners shall be elected, for proficiency in Classics, Mathematics, Natural Science, and Modern Languages respectively. The Regulations (37) order that "Natural Science shall be obligatory on every boy in the middle school, and either Natural Science or German on every boy above the middle school." Also (40) that "two Major and three Minor Scholarships shall be given for proficiency in Classics; one Major and one Minor for proficiency in Mathematics; one Minor for proficiency in French, and one in Natural Science." These are open to all boys between twelve and fifteen years of age.

I think it cannot but be felt that Natural Science has not been ignored in these regulations; it is not indeed put on an *educational equality* with Classics, but it is respectfully treated.

3. The Universities and other examining bodies affect us greatly. We at Rugby are principally influenced by Oxford and Cambridge, and it is of their influence only that I proceed to say a few words. It is plain that at the Universities some subjects must be universal, and some optional. The compulsory subjects are Latin, Greek, Mathematics, and Scripture Knowledge; optional subjects are numerous enough. Science ranks there with Law, History, Moral Science, Medicine, &c. Does Prof. Roscoe think that this is wrong? I really wish to know whether any thoughtful man who has considered the subject will say that science ought to be a *sine quâ non* for admission or for a degree at the Universities? *I* certainly think that science has its right position among the optional subjects. The point in this system that is more doubtful is the position of Greek, whether it might not be ranked with the optional subjects, and so give fair play to those schools and portions of schools which teach Science instead of Greek, and which are practically relegated to the rank of middle class schools (whatever they are called), because they have no outlet into the Universities. This is a change that has been already discussed more than once, and the opinions are, I believe, so nearly balanced, that the existence of a few more such schools, and a little pressure from without, will probably soon cause the change to be made. There is no doubt that the ready sympathy between the Universities and the educational needs of the country will be shown in this as in other things.

This is a digression, however. To return. Such being their system, the Universities are asked to examine schools and award leaving-certificates. I have reason for thinking that it was felt that this was not a time for fettering schools, or preventing educational experiments; they therefore declined to lay down *any* universal subject of education. They grant certificates without requiring a knowledge of even Latin and arithmetic. Every school may select its own studies. They will not, however, grant a certificate without a certain variety of attainment: four subjects must be taken, speaking generally, from three groups. Language, Mathematics, Literature, and Science form the groups.

It seems to me, therefore, not fair, not a statement of facts, to charge the University examination for certificates with "placing the science subjects in a distinctly inferior position to the older studies." The position is exactly identical. As a *leaving* examination nothing can be fairer.

What I pointed out in my first letter (Feb. 24) was that the *leaving* examination from school was in fact, to our boys, an *entrance* examination to the Universities; and in it they select, of course, the compulsory subjects of the Universities, for otherwise the certificate has no value. Science is not one of these compulsory subjects, and therefore the indirect action of these examinations is adverse to science. But I do not see how it can, or ought to be, otherwise; only I wish that their examination in science was a little more carefully arranged, with a view of forming at schools a sound method of teaching science.

The Universities of course affect us greatly by their scholarships in Natural Science, which do more to guide the teaching than anything else, and by their training masters. The influence of men like Maxwell and Clifton in inspiring teachers of Physical Science is very great; and when this influence is wanting in any subject at the Universities, the schools are the bodies which suffer. The Professors of Chemistry and Physics at the Universities are masters of the situation.

4. Head-masters have, of course, the chief power at schools of making science teaching effective or the reverse. This is a delicate matter for an assistant-master to speak of; and I have no right to discuss in this place—nor indeed elsewhere—how far the Regulations of the Commission and Governing Body are carried out in letter or in spirit, here or elsewhere.

But I may point out that, except in rare instances, head-masters follow, and do not lead, public opinion on educational points. The competition between schools is close; their prosperity depends on their meeting the demands of the public; and few men are bold and clear-sighted enough to make with success a move in anticipation of a demand from the public. At present a Balliol Scholarship, or other University Scholarship, are the grand advertisements; got at whatever cost to boy or school, they *pay*. And head-masters, being but men, are influenced by this. To get one such scholarship, except

in cases of rare genius in a boy, costs the school a good deal, not in money, but in efficiency. To get one you must spoil several. First-rate proficiency in a subject, it is believed, can only be got when many are working together in it. Competition is stimulated by numbers. The success is less brilliant when the racers are few. A form is somewhat disorganised, it is urged, if some boys drop Greek, and others drop verses, or composition altogether; and thereupon many are kept to swell the triumph of the few. The possible disorganisation is an imaginary evil, I believe, but a real argument none the less, and science suffers much at schools from a want of freedom given to boys to drop some other subjects and pursue it as a principal study.

Then there is the inevitable silent disparagement of non-appreciation. Some men have genuine sympathy with learning of all kinds, and can make others feel that they respect a learning they themselves do not possess. But such men are rare. It is too often made plain to boys who "take to science," that they are regarded as failures—as we hear of some "ne'er-do-weel" that he has "taken to" sheep-farming in Australia. It is the entire and transparent honesty of this opinion that makes it so effective, and this adverse influence, which is deeper than words, and often in flat contradiction to them, will only be eliminated by the general growth of public estimation of science, and by the fruits that education in science can show. For this we must wait.

5. The last influence is that of parents and the public generally. From them, as far as I can judge, there is no trace of a demand for a revolution in education. The only subjects on which there seems to me to be a strong and tolerably united opinion, are the postponement of Greek in the education of young boys, and a desire for greater weight to be given to arithmetic, good writing, and geography. The teaching of science is desired, principally on grounds of utility, not of training; and choice of the time of introduction of it, the order of the subjects, &c., the stratification of science, in a word, has not been considered, except by very few.

Prof. Roscoe thinks science ought to have "educational equality both in range and time with classics and mathematics." Here I distinctly differ. I maintain, after trial, that it is unwise, and unscientific from an educational point of view, to attempt to teach science at school to boys till they have attained a certain standard of knowledge in arithmetic, and a certain power of reasoning and language, as shown by their attainments in geometry and Latin. Let science be held before them as a thing to be enjoyed when they are older and more advanced. It is spoiled for them, and they are spoiled for it, by its being taught them too soon. The dicta of men like Faraday and Sir John Lubbock, and Roscoe are misleading opinion on this point, and I wish to record my protest against them. Do Sir John and the Professor know, have they the slightest idea what the standard of arithmetic is in the lower forms and among the new boys of a public school? I will tell them. This was the entrance paper I set in Arithmetic last January. By the Regulations, "No boy shall be admitted who cannot work sums in Fractions and the Rule of Three."

"RUGBY SCHOOL, JANUARY, 1876.

"*Entrance Examination.—Arithmetic.*

"You are required to satisfy the Examiners in this paper.

1. Subtract one hundred and seven pounds, nineteen shillings and sixpence three farthings from two thousand seven hundred and three pounds, and threepence halfpenny.

Multiply the result by seventeen.

2. Write out the table of square measure, and find the number of ounces in a ton.

3. If 49 tons 15 cwt. 1 qr. 13 lbs. of coal are distributed among 23 persons, how much will each receive?

4. Multiply 11*l*. 3*s*. $6\frac{5}{8}$*d*. by $3\frac{3}{7}$.

5. Simplify $2\frac{3}{4} \div 1\frac{5}{8}$ and $\dfrac{2\frac{1}{2} - 1\frac{1}{4}}{7 \div 5\frac{1}{4}}$.

6. If a man walk 4 miles, 1 furlong, 40 yards in one hour and 13 minutes, how far will he walk in two hours?

7. Multiply .105 by 3.027 and $.10\dot{5}$ by $3.02\dot{7}$.

8. Find the cost of 3,653 articles at 7*l*. 13*s*. $6\frac{1}{2}$*d*. each."

The plucking on this paper happily did not rest finally with me. But it may affect Prof. Roscoe's opinions if I tell him that if every boy had been required to answer one of the first three questions, and either 4 or 5, and 6, —[1] per cent. would have failed: and the average age of these boys cannot have been under fourteen. This is a stubborn fact. No doubt boys *ought* to know more. But they *don't*.

What, therefore, we insist on is that boys, when once in the school, shall not begin science till they know something of fractions, decimals, and square measure, and half the first book of Euclid. Does the Professor think our standard too high?

To sum up, therefore, what has been said. The commission and governing body secure fair play to science; the Universities do the same, though the new examination is, indirectly, rather adverse to it. Head-masters follow, and do not lead the public; and the public has no very decided opinions just at present.

If, therefore, I were asked what I think ought to be the programme of those who are interested in the progress of physical science and of sound education generally, in schools, I should reply that our great aim ought to be *the postponement of Greek in all schools, and its removal from the compulsory subjects in the examination for certificates that carry a University value*; that meantime we ought to use the certificate examination, and improve it; and to demonstrate, if possible, to unbelievers, the advantage it would be to some boys to drop Greek and composition for the purpose of scientific study, and that such a liberty would not injure the efficiency of schools in classics. It will be well also to watch with care the progress of schools in which Greek is not taught at all. No index to public opinion can be more valuable.

"The History of Education," Henry Sidgwick says,[2] "is the battle-ground and burial-ground of impracticable theories; and one who studies it is soon taught to abate his constructive self-confidence, and to endeavour humbly to learn the lessons, and harmonise the results of experience."

It is in this spirit—and I trust it is mine—that anything must be written that will now, in the present stage of the discussion, be a valuable contribution to the formation of opinion on this interesting and important question.

Rugby, March 6 JAMES M. WILSON

I should feel obliged if you would permit me to say that my views with regard to this question agree in the main with those of Mr. Hutchinson and Mr. Wilson.

The regulations of the Oxford and Cambridge Schools Examination Board were amended after the first examination in 1874, and the paper together with the practical work set last year was, in my opinion, sufficient in point of difficulty. Several of the candidates from Clifton, and doubtless from other schools, were quite prepared to work a much more difficult paper. That, however, is not the question which is to determine what shall be required of the average boy when he leaves school.

In Clifton College the Modern Side receives instruction in science at the rate of two lectures a week on chemistry and two on physics. Latin gets only three hours a week. A large number of boys (over fifty) attend voluntarily in the laboratory and thus have three or more hours a week of practical work, whilst a few of the more advanced receive two lessons in theoretical chemistry, besides doing a considerable amount of reading out of school. The subject is rewarded by marks at the same rate per hour as Latin, and also gets a fair share of prizes. In short, science at Clifton occupies a prominent and

[1] In the revise I have struck out this number. Its publication might be regarded as a breach of confidence. And it is almost incredible.

[2] "Essays on a Liberal Education." Macmillan, 1867.

honourable position in our curriculum. At other schools, as, for example, the Manchester Grammar School, I am told that even a larger proportion of the time of the boys is given to work of this kind; and on the whole I am inclined to think that, notwithstanding the reluctance of some of the old foundations to admit the interloper, yet that the prospects of science in connection with general education are exceedingly satisfactory and encouraging.

It would be a mistake to attempt to *displace* classical studies, as some people seem to wish, in favour of science or any other subject. It cannot be expected that all boys should have the same tastes or capabilities. It would be as much an error to compel a boy, who has shown no aptitude for science, to devote any large proportion of his time to that subject, when he might be getting on with his classics, as it would be to doom another to Latin prose when his heart was all the time in the laboratory. The true system I believe to be this. After passing through a junior school, in which all should be equally instructed in some branch of natural history or experimental science, boys should then be drafted off into one of three departments. There should be (1) a classical school, in which Latin and Greek should be the staple, though not to the exclusion of a certain modicum of mathematics and science; (2) a modern school, in which mathematics are predominant; and (3) a science school, in which languages, though subordinate to science, should not be altogether extinguished. This is very nearly the system pursued at Clifton, and I can testify to its practical convenience and success.

As regards the choice of subjects, though I believe chemistry is pre-eminent in its capacity for developing certain of the mental powers, I consider that the fullest advantage is not derived from it, unless it is taught in a certain way. I hold that teachers of chemistry *in schools* are wrong when they set about teaching boys according to the methods commonly in use in the instruction of ordinary chemical students. The latter have to apply their knowledge to practical purposes, and this is not the prime object to be kept in view in determining the educational value of a given subject.

And this leads me back to the question of examination papers. I consider that examiners have as much to learn as teachers in connection with their respective functions. At present it is too frequently, "How do you make this?" or, "What are the properties of that?" a style of question which is good enough in its way, but to answer requires very little intellectual effort. The preparation for such an examination is little better than "cram," and is of proportionately small educational value.

If examiners, whether in school or university, would take more pains in framing their questions so as to extract not alone that which is in the memory of the candidate, but to get the product of his brain, I believe great and important service would be rendered to scientific education.

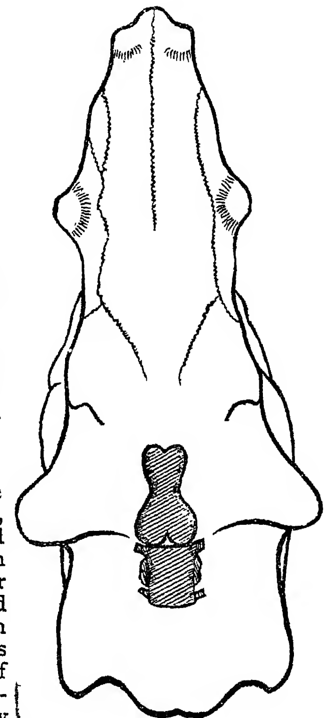
William A. Tilden

Clifton College, Bristol, March 6

PRINCIPAL CHARACTERS OF THE DINOCERATA

Under the above title, Prof. O. C. Marsh, of Yale College, has published several facts of great importance with reference to the structure of the huge Eocene Mammals of Wyoming, of which we have already given a short description (Nature, vol. vii. p. 366) from the same author's memoirs.

We now learn that the brain as known from the inside of the skull was very remarkable, being proportionately smaller than in any other known mammal, the Spermaceti and some other whales alone excepted. In *Dinoceras mirabilis* the entire brain was not greater in any of its transverse dimensions than the spinal canal in the cervical region. Its relative size and position can be best estimated from the accompanying drawing, copied from one given by Prof. Marsh, the brain in it being shaded, with a portion of the spinal cord attached. From the figure it is also evident that the olfactory lobes are proportionately large, at the same time that the cerebral lobes are hardly bigger than in some reptiles. The cerebellum must also have been small, whilst the cranial as well as the spinal nerves and the cord were immense.



The teeth are figured with their prominent V-shaped ridges, the dental formula being given as:—

$$i\,\frac{0}{3}\;c\,\frac{1}{1}\;pm\,\frac{3}{3}\;m\,\frac{3}{3}\times 2 = 34.$$

The upper canines were very long and pointed, and peculiar expanded descending processes on either side of the lower jaw seem to have acted as guards to protect them whilst the mouth was closed. The condyles of the lower jaw were transverse, and therefore only allowed of an up-and-down movement. The molars were peculiarly small for the size of the animal and of the skull. The creature must have been carnivorous, as mastication could only have been slight, and the food therefore nutritious.

The feet are figured. They were very elephantine, there being five digits on each; these, with the carpus and tarsus, being short and compressed from above downwards. The terminal phalanges were well developed. The other bones much resembled those of the elephant in size as well as contour. Prof. Marsh tells us that the head could evidently reach the ground, and that there is no evidence of a proboscis.

These characters all point to the fact that in Eocene times there lived an order of animals which have no representatives at the present day, and that they were highly specialised in some points of their structure, whilst in others they were equally ill-developed.

NOTES

We learn that a scheme is on foot for a memorial of the late Prof. Rankine. Students of Thermodynamics, Engineering, &c., will be doubly delighted to hear that the memorial is to take the form of an edition, in two handsome quarto volumes, of his valuable papers contributed to the various scientific societies and magazines.

A series of lectures upon zoological subjects will be delivered after Easter in the Zoological Society's Gardens, in Regent's Park, on Thursdays, at 5 p.m. The following are the titles, together with the days on which they will be delivered by the respective lecturers:—April 27, Mr. P. L. Sclater, F.R.S., on the Society's Gardens and their inhabitants; May 4, Prof. Flower, F.R.S., Rhinoceroses and Tapirs; May 11, Prof. Flower, Horses and Zebras; May 18, Dr. J. Murie, the Manatee; May 25, Prof. Garrod, On Birds; June 1, Prof. Mivart, On Bats; June 8, Mr. Tegetmeier, On Homing Pigeons;

June 15, Prof. Garrod, on Reptiles; Mr. J. W. Clark, on the Beaver and its distribution; June 29, Dr. Carpenter, on the Zoological Station at Naples.

WE are in a position to state that M. Leverrier has not accepted a seat in the Berlin Academy of Sciences, as was announced recently in a London daily paper. He would have been present at the meeting of the Royal Astronomical Society, to receive his medal, had he not been prevented by ill-health. Although not serious, the illness was sufficient to keep him at home for a protracted period.

WE have received the *Atlas Météorologique de l'Observatoire de Paris* for the years 1872, 1873, and 1874, which has been prepared from documents received and discussed by the Departmental Meteorological Commissions, the normal schools, the observers, and others, and published with the concurrence of the Scientific Association of France. This very valuable publication, giving in detail results of much of the important meteorological work now undertaken by France, together with separate discussions on inquiries of great interest by such writers as Prof. Raulin, MM. E. Belgrand, G. Lemoine, and Brault, we shall take an early opportunity of more fully bringing before our readers.

A DAILY weather report, by the *Deutsche Seewarte*, began to be issued at Hamburg under the direction of Dr. G. Neumayer, on 1st January last, which shows on one map embracing nearly the whole of Europe, the distribution of pressure, wind, and cloud, and on another, temperature, rainfall, and sea disturbance, along with a general review of the state of the weather in the morning, the changes that have occurred since the afternoon of the day before, and occasionally a forecast of the weather to be expected. The reports are based on weather telegrams received from twenty-seven places situated in different parts of Germany, supplemented by reports from Great Britain, France, Italy, Austria, Russia, Denmark, Sweden, and Norway. The report is a valuable addition to the daily weather maps of Europe, and considering the great ability of Dr. Neumayer and his coadjutors, the system will be most efficiently worked.

WE have received from the South Australian Institute, Adelaide, six valuable meteorological diagrams, representing the main facts of the rainfall at Adelaide from January 1839 to October 1874, at Melbourne from January 1855 to July 1874, and at Sydney from April 1840 to July 1874. The diagrams for Adelaide are particularly full, showing the rainfall each day for the thirty-five years, the annual amounts, and the monthly averages and extremes.

THE Central Committee for the participation of Germany in the forthcoming Exhibition of Scientific Apparatus has up to the present admitted 260 applicants, who will exhibit altogether 2,300 instruments. The British Government has afforded every facility to the exhibitors, having sent specially-fitted carriages to Berlin for the safe conveyance of instruments of great value.

AT a recent meeting of the Sedgwick Memorial Committee at Cambridge, the treasurer announced that the fund amounted to 11,500*l.* This sum is, however, insufficient for the purpose of erecting a Museum worthy as a building to commemorate the late Professor, and it is hoped that additional subscriptions will still be forthcoming. It is intended that the Museum should form part of a group of buildings for Natural Science purposes. The whole question is under the consideration of a Syndicate.

AT a meeting of the Senatus Academicus of Aberdeen University, held on Saturday, it was resolved to confer the degree of LL.D. upon Mr. Charles Meldrum, the Observatory, Port Loüis, Mauritius, and Mr. John Smith, Professor of Chemistry, University of Sydney.

A CROWDED meeting was held by the Italian Geographical Society on Tuesday morning in one of the large halls of the Collegio Romano for the purpose of taking leave of the Marchese Antinori, Signor Chiarini, Professor of Geology, and Capt. Martini, composing the expedition sent out to Central Africa. The President, Commendatore Correnti, ex-Minister of Public Instruction, addressed the meeting. Among the many distinguished persons present were Prince Humbert, Honorary President, and General Menabrea, member of the Council of the Society. In the evening a banquet was given to the members of the expedition, and yesterday they were to embark at Naples direct for Aden.

THE *Times* Berlin correspondent writes that Capt. Sosnovski, the Russian traveller, who has just threaded his way from the shores of China to the South Siberian frontier, has presented to his Government an explicit report upon new caravan roads to be formed through Mongolia.

M. GREARD, the Director of Public Instruction of the City of Paris, has just published his Reports, which contain a great number of interesting facts. In 1861, 48 children in each 100 were educated in the public schools of the city; in 1872 the proportion was 68 per cent.; but out of the remaining 32 per cent. only 20 per cent. are uneducated, the other 12 being educated in their families or in private institutions. The fact is all the more noteworthy that in the department of the Seine or suburban Paris, the number of schools and of pupils is diminishing. This is attributed to the impoverishment and sufferings resulting from the German and civil wars, which fell more heavily on the suburbs than on Paris itself.

M. ANSART, a captain in the French navy, has published, under the title "Anemology," an interesting article on the formation of winds, in the *Revue Maritime et Coloniale* for December. The principal aim of the author is to prove that the electrical attraction exerted on the clouds by the earth is an important factor in the generation of winds; the motions of the air being thus not merely dynamical as is generally supposed. Capt. Ansart is not the only meteorologist who has tried to take account of the electrical power of the earth. At the end of his essay he quotes the opinion published by M. Keller, who explains by attraction of the earth the production of waterspouts. He concurs in opinion with Capt. Ansart that the matter of the clouds under special circumstances is attracted by the negative electricity of the earth being strongly positively electrified. The rotation of a waterspout, according to Capt. Ansart, is caused by the attraction of the earth not being equally exerted on the whole of the surface of the cloud.

THE *Augsburg Gazette* states that the number of students registered in Berlin, of German nationality, is 1,884, in Leipzig 2,575, and in Munich, 1,087.

EARTHQUAKE shocks were felt in the province of Constantine, Algeria, at Philippeville and Gigelly, two sea-ports, on the night of Feb. 22–23. The exact times for Philippville were 1 and 1.30 A.M.; the direction north-west to south-east. Another motion was felt at Gigelly on the 23rd, at 4 o'clock in the afternoon. M. Bulard, Director of the Observatory of Algiers, expected other shocks on the 4th or 5th of March, and has published the prediction in the *Moniteur de l'Algerie.*

MESSRS. HENRY S. KING and Co., inform us that it was by an inadvertence that Bernstein's "Five Senses of Man" was advertised as ready; it will not be out for at least a fortnight.

WE have just received the first number of the Italian *Giornale del' Museo d'Istruzione e di Educazione*, containing forty pages of valuable matter connected with various departments of education. The Museum of which this journal is the organ, was founded

at Rome by decree of Victor Emmanuel in 1874, and is probably one of the finest and most complete educational museums in the world. It is freely open to the public, and teachers have ample facilities for taking advantage of its circulating library, and of the various other means which it possesses for furthering the cause of higher education.

A NEW French geographical journal has been established by M. George Renaud, a member of the Paris Geographical Society, under the name of the *Journal Géographique Internationale*, which will be published twice a month. Each number will contain a coloured map.

MR. CUNLIFFE OWEN, the director of the South Kensington Museum, visited on Saturday last the photographic workroom established in the *Moniteur* office, Quai Voltaire, Paris. The peculiarity of the process used is the reproduction of colours by a series of chromo-printings. It is a combination of photography and chromo-lithography, which gives astonishing results, chiefly in the reproduction of models of engines and *natures mortes*.

THE March part of the *Geographical Magazine* contains two maps by Mr. Ravenstein, in connection with Lieut. Cameron's recently-accomplished journey across Africa. One of these is of a portion of South Africa, illustrative of Cameron's route from Lake Tanganyika to the west coast, and the other is a map of the country between Lake Tanganyika and Nyangwe, according to Livingstone and Cameron. The same number contains an interesting account by Lieut. Liardet of an ascent to the lake on the summit of the island of Taruini, in Fiji.

"THE Study of Natural Science" is the title of an address delivered to the Natural Science Classes in the University College of Wales, by Mr. F. W. Rudler, F.G.S., recently appointed Professor of Natural Science in the College. Mr. Rudler has sound notions as to the relations which ought to subsist between scientific and literary training in education, and of the methods which ought to be followed in the study of science.

WE have received a copy of the rules, list of members, and Papers read before the Cambridge Natural Science Club The number of members is very limited, and the rules are sufficiently stringent to exclude all but men who mean to work. Some of the papers which have been read are of permanent value.

WE are glad to see that the Edinburgh Naturalists' Field Club, founded in 1869, is still in existence and evidently in a prosperous condition.

FROM its Tenth Annual Report, we are glad to learn that the North Staffordshire Naturalists' Field Club is in a prosperous condition; the number of members is now 330. The excursions and meetings during the past year appear to have been instructive and interesting. The Report contains the Annual Address of the President, Mr. C. Lynam, on the Sepulchral Monuments of Staffordshire. Other papers are: "The Geology of Needwood Forest," by Mr. W. Molyneux, F.G.S.; "Uriconium," by the Rev. J. S. Broad; "Ancient Church Bells in Staffordshire," by Mr. C. Lynam; and "Structural Features of Plants in relation to their uses in the Arts and in Medicine," by D. J. T. Arlidge.

PART 3 of Vol. I. of the *Transactions* of the Watford Natural History Society contains the following papers:—On the Botanical Work of the past Season, by R. A. Pryor, F.L.S., with a map of Hertfordshire; List of Works on the Geology of Hertfordshire, by W. Whitaker, F.G.S.; and A Few Words about some Local Ferns, by J. E. Littleboy.

IN the last-issued part of the Transactions of the Institution of Engineers and Shipbuilders in Scotland is a paper by Mr. James Brownlee "On the Action of Water and Frictional Resistance or Loss of Energy when flowing at various velocities through a nozzle with a converging entrance and diverging outlet," with two plates.

THE President and Fellows of Magdalen College, Oxford, have commenced free courses of lectures on botany, zoology, and chemical physics, for artisans resident in Oxford. They will be continued throughout the present and Easter Term and the Long Vacation on each Saturday evening. The lectures are conducted by Prof. Lawson and Messrs. Chapman and Yule.

MESSRS. LEWIS AND CUNNINGHAME, special assistants to the Sanitary Commissioners with the Government of India, have just published a Report describing a series of important observations on the Soil in its relation to Disease.

"LIST of Hemiptera of the Region West of the Mississippi River" (extracted from the *Bulletin of the Geological and Geographical Survey of the Territories*, No. 5, second series, Washington, January, 1876) is the title of a pamphlet by Prof. P. R. Uhler, who has thus added one to the many valuable hand-lists now being published in various parts of the United States. The need of monographs and synonymic lists in the present day is constantly making itself felt; without them the entomologist can scarcely keep pace with the rapid growth of his study; so that he hails the appearance of such a paper as the above, with its well-executed and clearly-defined plates, as a godsend, for which he can hardly be too grateful.

THE additions to the Zoological Society's Gardens during the past week include a Brown Monkey (*Macacus brunneus*) from Siam, presented by Mr. Thos. G. F. Hesketh; a Tyrant Eagle (*Spizaetus tyrannus*) from South America, a Many-zoned Hawk (*Melierax polyzonus*) from East Africa, two Brazilian Caracaras (*Polyborus brasiliensis*), white variety, from Patagonia, presented by Lord Lilford; two Common Pintails (*Dafila acuta*), three Spotted-billed Ducks (*Anas pœcilorhyncha*), eighteen Red-crested Whistling Ducks (*Fuligula rufina*) from North-west India, presented by Mr. E. C. Buck; a Ring-necked Parrakeet (*Palæornis torquata*) from India, presented by Mrs. Henry Kingston; a Cape Dove (*Æna capensis*) from Africa, presented by Miss Barrer; an Indian Elephant (*Elephas indicus*), a Secretary Vulture (*Serpentarius reptilivorus*) from South Africa, deposited; a Greenland Falcon (*Falco candicans*) from Greenland, purchased; a Great Kangaroo (*Macropus giganteus*), a Red Kangaroo (*Macropus rufus*), born in the Gardens.

ANNIVERSARY ADDRESS OF THE PRESIDENT OF THE ROYAL GEOLOGICAL SOCIETY, JOHN EVANS, F.R.S.[1]

II.

MR. EVANS, in continuing his address, spoke of stratigraphical geology and of palæontology, expressing his belief that all recent discoveries pointed to uninterrupted continuity in both regions. After briefly referring to the evidence found in Settle Cave of the pre-Glacial existence of man in this country, and to the Wealden boring, Mr. Evans spoke as follows:—

There is only one more subject on which I will say a few words, and which, as to some slight extent involving a question in which I am personally interested, I have kept for the end of my address.

It is one to which it appears probable that the earnest attention of geologists will immediately be called, namely, the water-supply of this vast metropolis. This is, indeed, not the first time that the attention of this Society has been called to it; for Professor Prestwich devoted to it a considerable portion of his presidential address in 1872. It has since been more fully discussed in the Sixth Report of the Commissioners appointed in 1868 to inquire into the best means of preventing the pollution of rivers, who have extended their inquiries somewhat beyond

[1] Continued from p. 356.

what appear to be the strict limits of their Commission. It is with their report that I am mainly concerned.

The Commissioners have expressed their opinion that the rivers Thames and Lea (or Lee, as the word is spelt in their Report) ought to be abandoned as early as possible, and especially the former, as sources of supply to London. They regard the condition of these rivers as hopeless, and point out that an abundance of spring- and deep-well water can be procured in the basin of the Thames and within a moderate distance of London; and they are further of opinion that the metropolis and its suburbs should be supplied, on the constant system, exclusively with this palatable and wholesome water.

They believe that within forty miles of St. Paul's a sufficient volume of deep-well and spring-water can be obtained for the present daily wants of the metropolis, but especially point to the chalk and upper green-sand above the Gault, as the sources of supply. They state that within thirty miles of London there is an area of 849 square miles "covered" by these formations, and that within 40 miles radius the area is 1,597 square miles.

They estimate, to a great extent guided by experiments carried on during many years under my superintendence, that the portion of the annual rainfall upon this large extent of porous rock, which sinks to reappear in springs and streams, may be taken at six inches annually, and point out that this amount of infiltration into the chalk area within thirty miles of the metropolis indicates the quantity of 202 millions of gallons daily, as the theoretical maximum supply available from that area. They suggest that the greater portion of this water, which now escapes in springs and in the river-beds at the lower levels of the absorbent district on which it falls, might be abstracted by a sufficient number of wells sunk below the present spring-heads of the district, and so constantly drawn upon, that there should always be a void for the reception of unusual rainfalls below the level at which the drainage of the district naturally escapes. They incidentally admit that any water drawn from the subterranean reservoir in the chalk by artificial means will be at the expense of the streams which now flow through the valleys in the chalk area, but do not give even a passing consideration to the effect upon that area of abstracting from it its natural supply of water, and conveying it —"convey, the wise it call"—to London—should the scheme they advocate ever be carried into effect.

It can hardly be believed that a proposal such as this, involving the diversion of the whole of the water from the natural springs and streams over an area of not less than 440 square miles—an area larger than that of several English counties—should have been brought forward without the slightest reference to what would be the result upon this vast extent of country, the inhabitants of which are to be sacrificed to the presumed needs of this overgrown city. It will, I think, come within the province of the geologist to point out not only where spring-water of good quality is to be obtained, but also what will be the effect of its abstraction upon the districts where it now exists in sufficient abundance to overflow into the streams. It will be for him to show what will be the effect of producing "a void below the level at which the drainage of the country naturally escapes;" how what are now fertile and even irrigated meadows will be converted into arid wastes; how watercress beds, now of fabulous value, will be brought to the resemblance of newly-mended turnpike roads; how in such a district all existing wells, many of them already some hundreds of feet in depth, will be dried, the mill-streams disappear, and even the canals and navigable rivers become liable to sink and be lost in their beds. And these results would, if the scheme were carried out, not be confined to some single spot, but would extend over hundreds of square miles.

It may perhaps be thought that I am exaggerating the size of the area, the natural water-supply of which it is proposed to abstract; but the calculation may be readily verified.

The quantity of water now daily supplied to London by the different water-companies, exclusive of the Kent Company, which already supplies deep-well water to the extent of 9,000,000 gallons daily, is stated to be 104,800,000 gallons. Now if the supply of 6 inches of rainfall per annum, absorbed over 849 square miles, be, as the Commissioners calculate, equivalent to 202,000,000 gallons daily, it is evident that it will require more than half that area to furnish 104,800,000 gallons daily, the exact figures being 440½ square miles.

It must, however, be remembered that the Commissioners regard this quantity as the theoretical maximum of water-supply available from such an area. And they are right in so doing; for in some years a far larger area would have to be exhausted in order to produce so large a water-supply, since not unfrequently the quantity of the rainfall which percolates to a depth of only 3 feet into the soil, instead of being 6 inches, as supposed in the calculation, is as low as 3 inches. For three years running I have known the percolation through a depth of 3 feet of ordinary soil covered with vegetation to have been on the average only 3½ inches, and through chalk under the same conditions, less than 5¼ inches. It would appear then that it would be safer to regard the available spring-water supply as not representing more than 4 inches of the rainfall per annum, instead of 6 inches, in which case the area requisite to supply 104,800,000 gallons daily would be 660 square miles.

To avoid any possible error, let us look at the matter from another point of view. One inch of rain falling over a statute acre produces, as nearly as may be, 100 tons, or 22,400 gallons of water. Dividing this by 30 as representing the daily consumption of one person, there would be enough for one person for 743 days, or, say, for two for one year. Four inches of rain would render each acre capable of supplying the wants of eight persons, so that a square mile of 640 acres would supply 5,120 persons for one year. Calling the population of the metropolitan area 4,000,000, and dividing that number by 5,120, we arrive at an area of 780 square miles as necessary for their supply.

There can therefore be no doubt as to the vast extent of country which the proposal of the Commissioners would place under unnatural conditions with regard to its springs and streams.

No doubt wells may, in some few instances, be placed in such a position as to affect but slightly the neighbouring streams. The wells of the Kent waterworks, for instance, which supply 9,000,000 gallons daily, are so placed as mainly to derive their supply from water that would otherwise find its way into the Thames by springs along its bed; indeed, from the amount of chlorine present in the water, it may be doubted whether some portion of it is not derived from the Thames itself by filtration through the chalk. It seems probable that in the valley of the Thames immediately above London there may be spots from which a limited supply of water might be pumped without much injury to the neighbouring property; but a wholesale abstraction of the entire supply of spring-water from an area of even 300 or 400 square miles could not be otherwise than most disastrous.

On looking at the actual chemical analysis of the waters supplied by the different companies, as furnished by the Commissioners, there would at first sight appear to be some difficulty in understanding their reasons for so highly commending the Kent Company's water, and so unhesitatingly condemning that of the other companies, if we are to take as our guide the "previous sewage or animal contamination," on which so much stress is laid. It is hard to comprehend why, if river or flowing water which exhibits any proportion, however small, of "previous sewage or animal contamination," is to be regarded as suspicious or doubtful, the water in wells, say 100 feet deep, may be allowed 10,000 pints in 100,000, or 1 pint in 10, and may yet be regarded as reasonably safe. For, in these deep wells, if at no great distance from a river such as the Thames, it by no means follows that there is not some amount of comparatively direct communication through which water may trickle rather than filter, and not improbably the river-water below London is more objectionable for drinking purposes than it is higher up the Thames.

Let us for a moment compare the "previous sewage or animal contamination" of the water supplied by the different companies deriving their water from the Thames and Lea with that of the Kent Company's water. I take the average of the different analyses of each, as given at p. 270 *et seq.* of the Report:—

West Middlesex	3·083
Grand Junction	3·226
Southwark and Vauxhall	2·983
Lambeth	3·081
Chelsea	2·785
New River (excluding 1868)	2·751
East London	2·304
Average	2·888
Kent Company	6·480

or upwards of twice that of any one of the other Companies.

In this average, however, is included the water from the wells at Charlton and Belvedere, both of which are condemned

by the Commissioners. Omitting these two, the average is 3·780, which is still far higher than any of the others.

If we refer to the headings Organic Carbon and Organic Nitrogen, there can be little doubt of the superiority of the Kent Company's water, but judging merely from the statistics under the awful heading of "Previous Sewage Contamination," that of the River Companies seems the purest.

Why the source of supply from the two rivers should be condemned as hopeless it is hard to determine. This startling recommendation to give up the supplies of water on which London for centuries has depended, is brought forward just at a time when the most strenuous efforts are being made to purify the rivers Thames and Lea, and but a few years after the Commissioners on the Water Supply of the Metropolis, within whose proper sphere this question lay, had reported that with perfect filtration and efficient measures taken for excluding from them the sewage and other polluting matter, these rivers will afford water which will be perfectly wholesome and of suitable quality for the supply of the metropolis.

It is not for me to enter into the chemical part of this question, but I may venture to express a doubt whether considerably more might not be done by increased reservoirs for subsidence, and by artificial aëration of the water, in addition to filtration, so as to carry still farther the oxidation of any organic matter it may chance to contain.

I have less hesitation in strongly insisting on the fact that, irrespective of the New River water, the metropolis is already supplied with 9,000,000 gallons per diem, or at least 2¼ gallons per head, of the deep-well water so highly commended, a quantity which would seem amply sufficient for dietetic and culinary purposes. I am, moreover, of opinion that the difficulty of distributing this water over the whole area by means of a second service distinct from that of the water for ordinary domestic purposes, though great, is by no means insurmountable. Even were the waters of the Thames and Lea unfit for drinking purposes, it is very far from being the case, that London is in the same plight as Coleridge's "Ancient Mariner," with—

"Water, water everywhere,
Nor any drop to drink."

Enough is already there for all culinary and dietetic purposes, could it but be distributed; and to lay out incalculable sums of money and inflict incalculable mischief, in order to import chemically pure water with which to lay the dust in our streets, and to flush our sewers, seems "a multiplying improvement in madness, and use upon use in folly." We might almost as well import wine for the purpose; and in that case the Commissioners might find a historical parallel in the proclamation of Jack Cade:—"Here, sitting upon London Stone, I charge and command, that of the City's cost, the conduits run nothing but claret wine the first year of our reign."

As deeply interested in the water-power and general prosperity of one of the chalk valleys within the fated radius of thirty miles, I may have spoken strongly on this question, and may not unfairly be accused of having done so from interested motives. No one, however, can submit silently to an insidious attack upon the property which he is fairly entitled to hold; and after carrying on experiments, for upwards of twenty years, as to the percolation of water to the underground springs in a chalk area, I may claim some experience in such a question, and much doubt whether my judgment is seriously distorted. Even should the abstraction of water be spread over a much larger area than has been supposed, so as to reduce the amount conveyed away from any particular district; or even should the gross quantity required prove less than supposed, it may be left to any one who will take the trouble to investigate the matter, to determine whether the effects if wider spread, or somewhat diminished in intensity, would be much less injurious. Any injury from this cause would moreover be felt with double intensity at those seasons, which are of by no means unfrequent recurrence, when even without this gigantic artificial abstraction, the water in the upper portions of the chalk district becomes short, and wells which during the previous season may have had fifty or sixty feet of water in them run absolutely dry.

It now only remains for me to thank the Council, the officers of the Society, and the fellows at large, for the uniform kindness and consideration which they have extended to me, not only during the two years I have had the honour of being your president, but during the eight preceding years, during which I was one of your secretaries. I look back with pleasure on the prosperity which, during those ten years, the Society has enjoyed, a prosperity which I hope may continue even in a greater degree, now that I quit this chair in favour of my old friend and fellow-secretary, Prof. Duncan, who is, in all respects, so thoroughly well qualified to fill it.

SCIENTIFIC SERIALS

THE *Journal of the Chemical Society* for January contains the following papers:—Isomeric terpenes and their derivatives (Part V.), by G. H. Beckett and C. R. A. Wright, D.Sc. The authors in this paper describe the results of their experiments upon peppermint camphor from Japan. This substance has been shown by Oppenheim to be an alcohol (menthylic alcohol) of the formula $C_{10}H_{19}OH$, which by the action of dehydrating agents yields menthene, $C_{10}H_{18}$, this latter substance when treated with bromine yielding a tetrabromide $C_{10}H_{18}Br_4$, which on heating splits up into hydrobromic acid and cymene. The cymene thus obtained is identical with those previously obtained from other bodies. The authors have examined also the toluic acid from seven different cymenes, and conclude therefrom that "by the action of a large number of agents on terpenes and bodies related to them, absolutely the same cymene results, this cymene being identical with the paramethylpropyl benzene recently obtained synthetically by Fittica." Clove oil hydrocarbons and the liquid oil from camphor sublimation have also been examined.—On the decomposition of stearic acid by distillation under pressure, by George Johnston. The oils produced contain, among other products, mixtures of seven paraffins with the corresponding olefines.—On tolyl-phenyl, a new hydrocarbon, by T. Carnelley, B.Sc. The hydrocarbon is produced by the action of sodium upon a mixture of bromobenzene and pure bromotoluene (1 : 4):—

$$C_6H_5Br + C_6H_4.CH_3Br + Na_2 = 2NaBr + C_6H_4 \left\{ \begin{matrix} CH_3 \\ C_6H_5 \end{matrix} \right.$$

The behaviour of this hydrocarbon on oxidation is described, and and also some of its nitro and amido substitution derivatives.—A simple form of gas regulator for maintaining a constant temperature in air-baths, water-baths, incubators, &c., by F. J. M. Page, B.Sc.—The remainder of the journal is devoted to abstracts from foreign periodicals.

THE January number of the *Ibis* commences with a paper by Mr. Robert Ridgway, of the Ornithological Department of the United States National Museum, Washington, entitled "Second Thoughts on the genus *Micraster*," in which he modifies his view previously expressed as to the reduction of the number of species, from an examination of the specimens in Messrs. Salvin and Godman's collection. The same author also writes on the genus *Glaucidium*, embodying the results of Mr. Sharpe's criticism of a previous paper by him on the same subject; *G. jardinii* is figured.—Mr. D. G. Elliot has remarks on some type specimens of Trochilidæ from the museums of Neuchâtel and Florence; and notes on the Trochilidæ. In the former paper three of Tschudi's types—*Bourcieria insectivora*, *Heliodoxa leadbeateri*, *Leucippus leucogaster*—are discussed. The male of the first is described; *Trochilus otero* (Tschudi) is the second; the third is one of two species only of the genus. Four of Sig. Benvenuti's types are described. *Mellisuga judith* is *Panoplites flavescens*; *Mellisuga salvadorii* is the female of *Cynanthus cyanurus*, *Mellisuga ridolfii* is a female of *Eriocnemis vestita*, and *Polytmus cecilæ* is *Campylopterus lazulus*. Mr. Elliot's second paper is on the genus *Lampropygia*.—Mr. C. Bygrave Wharton has Notes on the Ornithology of Corsica, describing 113 species, mostly from the west coast.—Mr. R. B. Sharpe gives Part I. of Contributions to the Ornithology of Borneo, with a plate figuring *Orthotomus borneonensis* and *Calamodyta doriæ*, based on a collection made by Mr. Arthur Everett, *Circus spilonotus*, *Copsychus problematicus* (sp.n.), *Brachypodius immaculatus* (sp.n.), *Herpornis brunnescens* (sp.n.), *Henicurus ruficapillus* are the species described for the first time from the island. Mr. Sharpe also determines two new species of South African birds collected by Mr. F. A. Barratt near the Macamac gold-fields. They are *Andropadus flavostriatus*, and *Bradypterus barratti*.—Mr. J. H. Gurney continues his notes on Mr. Sharpe's Catalogue of the Accipitres in the British Museum, discussing the Buteoninæ.—Mr. H. E. Dresser gives notes on Severtzoff's Fauna of Turkestan.—Prof. Newton writes on the assignation of a type to Linnean genera, with especial reference to the genus *Strix*.—Messrs. H. Seebohm and J. A. Harvie Brown give notes on the birds of the Lower Petchora, based on an expedition made there last summer.

SOCIETIES AND ACADEMIES

London

Geological Society, Feb. 23.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—The Rev. David Charles, D.D., Thomas Musgrave Heaphy, C.E., William Smethurst, Edward Horatio W. Swete, M.D., and John Thomas Young were elected Fellows, and Prof. Joseph Gosselet, of Lille, a Foreign Correspondent of the Society.—The following communications were read :—On the greenstones of Western Cornwall, by Mr. John Arthur Phillips, F.C.S. In this paper the author brought forward evidence to show that the so-called "greenstones" of Penzance really belong chiefly to the following three classes :—*a*. Gabbros or Dolerites, in which the originally constituent minerals are either to a great extent unchanged, or, sometimes, almost entirely represented by pseudomorphic forms. *b*. Killas, or ordinary clay-slates. *c*. Highly basic hornblendic rocks, exhibiting a tendency to break into thin plates; these under the microscope present the appearance of metamorphosed slates. Slaty rocks of a character intermediate between *b* and *c* also occur. In the Cape Cornwall district the "greenstones" are chiefly hornblendic slates, sometimes with veins or bands of garnet, magnetite, or axinite. The rocks near the Gurnard's H ad are almost identical with those of Mount's Bay. The crystalline pyroxenic rocks and metamorphic slates of the St. Ives district exactly resemble those of Penzance. The greenstones between St. Erth and St. Stephen's are probably altered ash-beds or hardened hornblendic slates; unlike the hornblendic and augitic rocks of the other districts, they do not occur in the immediate vicinity of granite, but elvan courses are always found near them. The percentage of silica in the two series of rocks is nearly constant; the hornblende slates contain about 10 per cent. less silica than the crystalline pyroxenic rocks, and there is an excess of iron oxides to nearly the same extent, their composition in other respects being very similar. The Killas is an acidic rock of essentially different chemical composition.—On columnar, fissile, and spheroidal structure, by the Rev. T. G. Bonney. Some of the above structures have comparatively recently been discussed by Mr. Mallet and Prof. J. Thomson. Both these authors agree in attributing columnar structure to contraction due to loss of heat while cooling, but differ in their explanation of cross jointing and spheroidal structure. In this paper it is sought to show that the principle proved by Mr. Mallet to be the explanation of the columnar structure is capable of a wider application. After a brief notice of some instances of columnar structure, the author described cases of a fissile structure seen in certain igneous rocks (especially in the Auvergne phonolites), closely resembling true cleavage, and often mistaken for it; also the tabular jointing of rocks; a peculiar form of this, where most of the segments are of a flattened convexo-concave form; spheroidal structure and cup-and-ball structure. He showed by examples that Prof. Thomson's explanation of spheroidal structure was inadequate, and gave reasons for considering all these structures to be due to contraction. He also discussed more particularly the cup-and-ball structure, giving reasons for thinking that the spheroidal and the horizontal fissures were often to some extent independent of each other.

Physical Society, Feb. 26.—The president, Prof. G. C. Foster, F.R.S., in the chair.—The following candidates were elected members of the Society :—The Rev. R. Abbay, M.A., and Mr. W. Bottomley, sen.—Mr. A. Haddon exhibited and described a form of tangent galvanometer, so arranged that by the aid of an electric lamp an image of the needle can be projected on the screen, and its deflections thus made evident to large audiences. A horizontal beam of light falling on a mirror inclined at 45° is thrown vertically upwards. In its path it meets with a glass box containing a lozenge-shaped magnet about three-quarters of an inch long; above this needle is a graduated semicircle. The pivot supporting the needle is fixed in the centre of the glass plate which forms the bottom of the box. Above this box is a lens, and on the top of the whole is a second reflector parallel to the first. On either side of the needle is a hoop of stout brass wire, fourteen inches in diameter, one end of each hoop being insulated by a piece of ebonite, while the other end is in metallic connection with a brass ring which slides easily over the circular base of the instrument. The hoops are separated from each other by a distance equal to half the diameter of either hoop, *i.e.*, 7 inches. The instrument having been placed at a distance from the screen equal to the focal length of the lens, and the needle brought to zero by rotating the graduated scale, the hoops are placed parallel to the magnetic meridian, and the instrument is ready for action. As an illustration of the manner in which the galvanometer is employed, Ohm's Law was proved in the cases of large and small external resistance.—Mr. O. J. Lodge, B.Sc., then described some investigations on which he has recently been engaged in reference to the flow of electricity in plane bounded surfaces, in continuation of a paper read before the Society in the early part of last year, by Prof. G. C. Foster and himself. After some introductory considerations, he pointed out that all the conditions of the flow of electricity are known for any number of poles in an unlimited sheet. The problem then consists in reducing cases of poles in bounded plates to corresponding cases in the unlimited plane, such that the flow conditions on the bounding line may be the same in both cases. The determination of these data, however, for limited planes of certain forms presents considerable difficulty. In studying questions of this nature there are two kinds of lines which must be considered. These are "equipotential lines," *along* which no electricity passes, and "lines of flow," *across* which no electricity passes. The boundary of any conducting surface will of course always be a line of flow, and, in a bad conductor, we can form an equipotential line by laying a band of copper in the required direction. If, therefore, in studying a surface of limited extent in contact with an electrode, we can find a point or points outside the surface such that, if they be made electrodes, the boundary line of the surface becomes a line of flow, we are at liberty to treat the surface as part of an infinite plane, and all the circumstances are therefore known. To take the simplest case, a straight line in an infinite surface will be a line of flow if equal sources be placed in pairs on opposite sides of the line so that one is the virtual image of the other; but, if the components of each pair are of opposite sign, it becomes an equipotential line. To make a circle of radius (r) an equipotential circle, we require a source A, within, and a sink B, without, such that $CA.CB = r^2$. To make it a line of flow we require two sources, such that $CA^1.CA = r^2$ and an equal sink at C, the centre of the circle. The cases of an infinitely long straight strip and of a surface bounded by two straight lines inclined at an angle θ were then referred to, and Mr. Lodge showed that the first requires an infinite number of external sources arranged on a straight line, and the second an infinite number on a circle except when θ is a submultiple of π, the number then becoming finite. Diagrams of the images for certain cases of triangles and squares were also shown. The dimensions of the electrodes in contact with conducting surfaces are not matters of indifference. In a plane bounded by straight lines the electrodes within and without the boundary are of equal size, but when the boundary is a circle the areas of electrodes vary as the squares of their distances from the centre. It was then pointed out that not only the poles may be reflected in this way, but also every point in the sheet; and if the lines of flow or of potential are drawn inside a given circle for any arrangement of poles, the lines outside can be immediately obtained from them by inversion with regard to the centre of the circle by means of a Peaucellier cell. The author then described the manner in which the principle of Wheatstone's Bridge can be employed for tracing out lines of equal potential. If A and B be a source and sink on a conducting ring, and P any point on the ring between A and B and Q any point between B and A, then P and Q are of equal potential whenever $\frac{PA}{PB} = \frac{QA}{QB}$. If now the wire under the point P be flattened out into a surface, the above expression holds good for a certain line on that surface, which is therefore an equipotential line. Similarly by flattening out the wire under the point A, the line for which the expression then holds good is a line of flow for a certain distribution of poles. At this point the reading of the paper was adjourned to the next meeting of the Society.—Prof. McLeod exhibited a glass plate covered with a film of silver which had in places been deflagrated by means of Leyden jars, the poles being placed at varying distances apart. The form of the surface acted upon tended towards the Lemniscate of Bernouilli.

Paris

Academy of Sciences, Feb. 21.—Vice-Admiral Paris in the chair.—The death of M. Brongniart was announced.—The following papers were read :—Meridian observations of small

planets, made at the Observatory of Greenwich (sent by the Astronomer Royal) and at the Observatory of Paris, during the fourth quarter of 1875, by M. Leverrier.—Theorems relative to the displacement of a plane figure, two points of which glide in two curves of any order and class, by M. Chasles.—Remarks on the laws of storms, by M. Faye. The older meteorology places the origin of great atmospheric movements in the lower layers, the new meteorology traces them to upper currents of the region of cirrhus.—On fire-damp, by M. Faye. Instead of trying to suppress all causes of ignition (which is evidently impracticable, and has for result the allowing of large quantities of gas to accumulate till an explosion comes), would it not be well to supply the ceilings of the galleries with small open lamps every ten or twenty metres, so as to constantly burn the gas as it was presented? M. Berthelot gave some reasons against this method.—On the rotatory power of styrolène, by M. Berthelot.—On the invariability of great axes of the orbits of planets, by M. Tisserand.—Report on an apparatus of M. Vinot for recognising stars.—On the principles which ought to govern the construction of common lodgments (for men and animals), by M. Tollet. Outline of memoir. Barracks constructed, under the author's directions, for the eighth Army Corps, have realised an economy over the old system, of 300 francs per man, and 50 to 60 francs per horse, or 600,000 to 800,000 francs per regiment.—On the coefficient of dilatation of the air under atmospheric pressure, by MM. Mendéléeff and Kaiander. The most probable number is $\alpha = 0{\cdot}0036843$, or about $\frac{11}{2986}$ instead of $\frac{11}{3000}$, which has been adopted hitherto.—On some remarkable points in magnets, by M. Blondlot. If a very short magnetic needle, supported at its centre of gravity, be carried along near the surface of a magnet, then among its varying directions, those normal to the surface of the magnet are remarkable; the points to which they correspond M. Blondlot terms *orthogonal points*. One property of these points is that if a small magnetic body be placed at one of them, more mechanical work will be required to remove it from there to an infinite distance, than if it had been placed at any other neighbouring point on the surface of the magnet. Another property: the positions of equilibrium of a small magnetic body in relation to a magnet are precisely the orthogonal points.—Composition of the dark matter that is obtained in calcining ferrocyanide of potassium, by M. Terreil. It is a mixture containing, in minute division, cast-iron, magnetic oxide of iron, free carbons, and a small quantity of cyanide of potassium.—On the formation of anhydrous acids of the fatty and the aromatic series, by the action of phosphoric acid on their hydrates, by MM. Gal and Etard.—On the products of the action of chloride of lime on amines, by M. Tscherniak.—Reply to the reclamation of M. Plateau, on the subject of digestion of insects, by M. Jousset. M. Jousset disputes M. Plateau's statement that in insects in the normal state, the digestive juices are all alkaline or neutral, never acid; also that the liquid secreted by the gastric cœcums acts on starch but not on albuminoid substances.—M. Husson gave details of a process for testing, by means of sulphate of soda, the resistance of stones to frost.—M. Beyris described a convenient syphon, which consists of a caoutchouc tube; one end has a valve opening inwards, the other a stop-cock. The tube, stretched straight, is filled with liquid and the cock closed; you then put the valve end in the liquid, curve the tube, and open the cock.

Feb. 28.—Vice-Admiral Paris in the chair.—The following papers were read:—On the explosion of powder, by M. Berthelot. The chemical transformation is expressible, in every case, by a simultaneous system of very simple equations.—Researches on a sulphate which seems to contain a new oxide of manganese, by M. Fremy.—On the influence of mould on the nitrification of azotised substances of organic origin, employed as manures, by M. Boussingault. In sand and chalk there was little nitrification; it was in mould already nitrifiable, that all the azotised organic matters developed most nitric acid and least ammonia.—On fire-damp, by M. Faye. The ascent of the light protocarburetted hydrogen to the upper parts, takes place immediately, and it would there be burnt without danger. M. Berthelot replied.—On the methods of meteorology, by M. Sainte-Claire Deville.—Proposal made by Bouguer, in 1726, for obtaining from the log-books of all ships, by professors of hydrography, information useful to navigation, by M. de la Gournerie.—M. Dupuy de Lome, in presenting a work by M. Ledieu, "Les Nouvelles Machines Marines," recommended it for the application made of the mechanical theory of heat, to comparative examination of new engines.—Report on the memoir published by Messrs. Noble and Abel, "Researches on explosives, fired gunpowder." —Report on a memoir of M. Alb. LePlay, on a system of irrigation of meadows by means of rain-water in the mountainous and impermeable strata of Limousin.—Note on the meridian circle of the imperial observatory of Rio de Janeiro, by M. Liais. —The heart experiences at each phase of its revolution changes of temperature which modify its excitability. Note by M. Marey. The cooling corresponds to the phase of less excitability.—On the oil of Elæococca, and on its solid modification produced by the action of light, by M. Cloëz.—Means of preventing explosions of fire-damp, by the employment, *a tergo*, of compressed air, by M. Buisson. He would convey pure compressed air in pipes to the bottom of the mine, and drive the vitiated air outwards.—Note on the tracing of gearings by arcs of a circle; improvement on the method of Willis, by M. Léauté.—On some combinations of titanium (second note), by MM. Friedel and Guérin. This treats of the oxychloride and the sesquioxide. — On sulpho-phenylurea, by M. de Clermont.—On the antiseptic properties of borax, by M. Schnetzler. The body of a horse which had lain four months in a layer of borax earth in California, was quite fresh and odourless, the pupil clear and bright, the hair supple and well attached. —Reply to M. Glénard's last note on the *rôle* of carbonic acid in the phenomenon of spontaneous coagulation of the blood, by MM. Mathieu and Urbain.—On the reducing sugar of raw sugars, by M. Müntz.—Note on a new genus of fossil Entomostraca from the carboniferous system of Saint Etienne (*Palæocypris Edwardsii*), by M. Ch. Brongniart.—On the half November oscillation in America, by M. Hinrichs. This is as well marked, from Iowa up to Newfoundland as in Europe and Algeria. Curves are given.—On the manufacture of superphosphates destined for agriculture, by M. Millot. The retrogradation of these, after their ordinary preparation, is due to the presence, in the natural phosphates, of sesquioxides, and especially of sesquioxide of iron. —On movement in the hairs and foliar laciniations of *Drosera rotundifolia* and in the leaves of *Pinguicula vulgaris*, by M. Heckel. This refers to the action of chloroform and sulphuric ether placed near the plant under a bell jar. The effect was at first irritant, but, where the dose was not too strong (*e.g.*, three drops of chloroform) the organs soon returned to a state of repose. The jar having been removed, it took eighteen minutes, in this case in open air, for the irritability to be removed.—Meteoric combustions, by M. De Fonvielle. He suggests a method of ascertaining aërostatically the amount of dust in a given layer of air. At the end of a pole is placed a surface of some square decimetres, held horizontal, one of the sides covered with very pure glycerine. Let H be the vertical height traversed by the aërostat, S the sticky surface in square decimetres, and p the weight of dust received. The amount in a cubic metre will be $\frac{p \times 100}{HS}$.—Reclamation of priority concerning the mechanism of an electric lamp, presented by M. Girouard.

UNIVERSITY REFORM

THE discussion in the House of Lords on the second reading of the Oxford University Bill cannot be said to have been satisfactory. Those who took part in the debate were, almost without exception, Oxford men with high honours; and they evidently represented the opinions of the majority of Oxford residents. It is, indeed, a singular circumstance that there should be among the peers so large a proportion of persons who have gained first-classes, and who have themselves held "idle fellowships;" a proportion greater than can be found in the House of Commons. But the experience contributed by them, however valuable, ought not to have monopolised the whole discussion of the matter in a legislative assembly. Such experience is of the nature of one-sided evidence, which should be heard and weighed before a decision is reached; but which cannot be permitted to substitute itself for a thorough discussion of a subject of national importance. This aspect of the debate is the more to be regretted, because it will tend to encourage the feeling, which seems to be already predominant at Oxford, that the limited vision of the present race of University residents, together with their own pecuniary interests, is to determine the course of academical reorganisation. The hopes raised by Lord Salisbury's first speech will be dashed to the ground, if such petty matters as the difference between the legislative functions of convocation and congregation, the influence of the parochial clergy on either body, or the period during which an "idle fellowship" should be tenable, are thrust forward as the supreme considerations. These subjects, no doubt, require to be discussed and settled, once and for all; and it is, perhaps, an omission that they have not found a place in the Government measure. But no misfortune would be graver than if it were to go to the country, as the Liberal peers seem to wish, that the Bill does not contain principles of reform, in comparison with which these details sink into their proper insignificance.

Lord Salisbury's speech was welcomed, certainly by men of science, and we believe also by all those whose ideal of a university is not confined to what they learned during their adult school-days at Oxford or Cambridge, because he unhesitatingly announced two new principles, upon which the whole merits of the scheme turn. He proposed that the University should be endowed at the expense of the colleges, and that scientific research should take its place in the University by the side of religion and learning. Now, these two main principles were entirely disregarded in the discussion of last Thursday; or, when they were referred to, were "damned with faint praise." The Archbishop of Canterbury, whose speech was, on the whole, worthy of his position, professed himself ignorant of the precise meaning to be attached to the word "research;" as if there had not been, during the last three years, abundance of discussion on the subject in the press, and as if it had not been defined in the report of a Royal Commission. Both Lord Carlingford and the Earl of Morley reproduce the old argument, which to those familiar with the topic has long ago been worn threadbare, that the endowment of teaching professors is the only endowment of research which is either desirable or possible. It is not necessary in these pages to show how entirely is this objection founded upon ignorance. It is enough to observe that those very persons who are the most ardent advocates of the present system of awarding fellowships as sinecures, express themselves as most fearful of the danger of opening these sinecures to the physical sciences, and imposing on their holders the duty of original investigation. Lord Morley was in his day a distinguished classical student at Balliol College; but, so far is he from understanding the new demands of the present time, that he concluded his speech with the following idle peroration:—"I trust that the University, reinforced by the proposed aids, will take up the proud position *she has so long held*, and will, I hope, long continue to hold, as *the head and centre of all science* and learning." With regard to the proposal to satisfy the admitted wants of the University out of the surplus income of the colleges, hardly a word was said. Everybody was too anxious to support the condemned system of "idle fellowships," to bestow a thought upon the profitable uses to which these misapplied funds might be devoted. And so the House of Lords read the Oxford University Bill a second time, without any deliberate consideration of its essential features, but evidently prepared to dispute in Committee over all sorts of uninteresting details.

There is, however, one important point, on which not only the House of Lords, but also the nation at large, seems in danger of being misled. This has reference to the intentions of founders, and the original object for which fellowships were endowed. It seems to be universally assumed that the intention of the founders was primarily to promote religion, and secondarily education. "Orignally," said the Earl of Carnarvon, "religion was the object of the University; then, after a struggle, learning was added;" and now it is proposed to complement the two former by the addition of research. Against the theory implied in the last clause nothing can be urged; but the two former statements represent a most perverted view of history. The Archbishop of Canterbury, who ought to be better informed, is equally wrong, though less positive. "We know very little, perhaps, now of the exact intentions of the founders. We do know that many of them were desirous to benefit their own souls by having masses celebrated in their own Colleges; . . . but when that is said, we know very little more than that they had a general desire to promote education." Now, as a matter of fact, there is no historical evidence whatever, to show that the University or the colleges commenced with religious observances, and that learning had a hard fight to enter in. So far as we know anything about the condition of the University of Oxford in the pre-collegiate epoch (and it is true that our knowledge of that period is very small), it is certain that the University of Oxford, like the sister University of Paris, was an assembly of teachers and students, by no means of priests and monks. Study was the primary object then, as later, to which religious functions were only subordinate. No doubt the majority of the learned men were *clerici*, *i.e.*, in orders, but so were the lawyers at that time, and the Universities are no more ecclesiastical corporations than

are the Inns of Court. From the date of the foundation of the first college our knowledge becomes more definite. The original statutes have been preserved, and were published to the world by the University Commissioners about twenty years ago. The evidence, therefore, of the intentions of the early founders of fellowships is abundant, and it is also decisively clear. It was, no doubt, desired that the study of Theology should be supreme, and ample provision was made for divine worship; but it must be recollected that in those days Theology included Law, and did not exclude Natural Philosophy. But what the founders had foremost in view, as might easily be shown by copious extracts from their statutes, was not religion, or even education, but advanced study. The few earliest colleges make no reference at all to the endowment of teaching. Their fellowships were established "for the support of indigent scholars in the University of Oxford, who are bound to study and make progress in the divers Sciences and Faculties." The function of teaching was left to be performed by the University, and all those who had taken the higher degrees enjoyed the privilege, as they were under the obligation, of giving instruction. "To study, not to teach, was the business of the Fellows. The founder of Queen's College has even expressly stated that he intends his benefaction to relieve his Fellows from the necessity of teaching." The full period of study required for the degree of Doctor lasted for thirteen or nineteen years, varying in the different faculties; and the fellowships were intended to support poor students during this long season of probation. Nor must it be supposed that Theology and the Classics were the only subjects meant to be encouraged. Many of the founders made provision for the study of medicine; at New College Astronomy is specially mentioned; and William of Waynflete, in the statutes of Magdalen, expressly prescribes Natural Philosophy as one of the three departments of knowledge which the Fellows were to cultivate. Other instances of a similar nature might be quoted; but nothing further is required to prove what the colleges themselves will scarcely admit, that the fellowships were given not as prizes to stimulate clever boys, nor as subsidies for academical teachers, but to promote mature study. The appeal, therefore, to the intentions of the founder does not lie in the mouth of the advocates of the existing order of things, but is one of the strongest arguments that can be used by those who support the endowment of research, which turns out to be merely the restoration of the old practice.

MINERALS OF NEW SOUTH WALES

Mines and Mineral Statistics of New South Wales. Compiled under the direction of the Hon. John Lucas, M.P.; also "Remarks on the Sedimentary Formations of New South Wales." By the Rev. W. B. Clarke, M.A., F.G.S. (Sydney, 1875.)

THE volume now before us is a companion to that we reviewed recently in this journal on the minerals and rocks of Victoria,* and like it has been called forth by the necessity of cataloguing and describing the collection of specimens exhibited at the Metropolitan Intercolonial Exhibition held at Sydney in 1875, which consisted of rock-specimens, fossils, samples of coal, ores of iron, and other metals, collected by the Examiner of Coal-fields, the Government Geologists, and furnished to a large extent by the owners of mines, the whole being arranged by Mr. C. S. Wilkinson, Government Geologist to the colony. The volume also contains statistics of the minerals raised in 1874 and preceding years. These do not pretend to be more than approximations, but they are sufficient to enable us to see the strides this great colony is making in the development of those mineral treasures which are almost lavishly bestowed throughout the area already explored, and which give promise of still wider distribution; meanwhile, the authorities seem fully alive to the importance of having accurate returns. It is stated that "the arrangements for the future are such as it is hoped will secure the collection, publication, and preservation of complete and authentic returns, and no pains will be spared to render our records of the past more complete than they are at present."

It may interest our readers, however, to be put in possession of the latest returns, which are for the year 1874, and are as follows:—

	Total Value.
Gold	£30,656,246
Coal	6,565,328
Tin	866,461
Copper	807,476
Oil-shale (Kerosine)	261,414
Silver	77,216
Iron	15,434
Antimony	897
Total	£39,220,472

It is impossible to rise from a perusal of this volume without the conviction that the resources in not only the precious metals, but the more useful minerals—coal and iron—are practically inexhaustible, and that being developed by British colonists are destined, or are at least calculated, to produce a nation rivalling the mother-country in manufacturing industry. We gather that the colonists now fully perceive this themselves; and for this they are to no small degree indebted to the voluntary labours of that veteran geologist, the Rev. W. B. Clarke, who for a quarter of a century has been engaged in exploring the interior of the continent and unfolding its geological structure. A more detailed survey is now in progress, which has been attended with highly encouraging results; and it would be well for intending settlers to possess themselves of all the available information afforded by the maps and reports of the geological surveyors, as by this means they may become the happy possessors of treasures lying below the surface. Meanwhile, sufficient is known to enable us to give a short sketch of the physical features and geological structure of this great colony.

New South Wales is bounded on the south by the Murray River—separating it from Victoria—and on the north by a line generally corresponding to the 29th parallel, by which it is separated from Queensland.

The coast line extends from Cape Howe to Point Danger, a distance of nearly 700 miles, with the Ports of Wollongong, Sydney, Newcastle, and the Clarence River at intervals. At a distance from the coast-line, varying

* "Rocks and Minerals in the Melbourne Museum," NATURE, vol. xiii. p. 165.

from 30 to 150 miles, runs the Cordilleras range of mountains—sometimes serrated, at others tabulated—and reaching elevations of 6,000 or 7,000 feet. "The highest point in all Australia," is at the head of the Murray River and near the boundary with Victoria, being, according to Strzelecki, 6,500 feet above the sea, but according to the later observations of Clarke 7,175 feet. From the base of this range the country extends in a spacious plain to the sea margin, and on the west into the great central wilds of South Australia, and the regions watered by the Darling, the Lachlan, and the Murrumbidgee Rivers. The central tract from the coast to the Cordilleras is occupied by the Sydney coal-field, having a sea-board of about 200 miles, and an area of over 15,400 square miles—as estimated by Mr. J. Mackenzie, F.G.S., Examiner of the Coal-fields—richly stored with coal, and, along its western margin, with iron. Newcastle in Australia is a coal-shipping port, as well as the Newcastle in the old country, and from the number of projected lines of railway communicating with it, it is clear that the neighbouring collieries are destined to distribute mineral fuel into the far interior, as well as to the ocean steamers and coast towns.

Another point of similarity between the mother-country and her daughter, dates from the far-off ages of Geologic time; for Mr. Clarke and other geologists have clearly demonstrated that the coal-beds of New South Wales and of Britain were elaborated in Nature's workshop during the same Geological period; and on comparison it will be found that the general succession of the members of the Carboniferous series in the North of England and Scotland have their equivalents, as nearly as possible, at the Antipodes. This may be accidental, but it is at any rate a striking illustration of the prevalence of similar conditions over wide areas of the globe during the Carboniferous period.

The general succession of the Upper Palæozoic series of New South Wales and their possible British representatives is as follows:—

New South Wales.	Great Britain.
(*e*) *Wianamatta Series*.—Shales, with fish (*Palæoniscus*), fresh-water shells, and plants. 500 feet.	(*e*) Possibly Permian Beds.
(*d*) *Hawkesbury Series*.—Chiefly sandstones, with ferns (*Glossopteris browniana*). 1,000 feet.	(*d*) Upper Red Sandstone of the Glasgow district.
(*c*) Upper Coal-measures of Newcastle, &c., with plants—as *Glossopteris*, *Sphenopteris*, Conifers—with sixteen coal-seams over three feet in thickness. 480 feet.	(*c*) Upper coal-measures of Scotland, with Millstone Series at base.
(*b*) *Upper Marine Beds*.—Shales, sandstones with coal-seams, &c., with numerous Lower Carboniferous shells (*Spiriferæ*, *Producti*, Crinoidal stems. 350 feet. *Lower Coal-measures*. — Shales, sandstones with similar fossils. 100 feet.	(*b*) Lower coal-measures of Scotland of the Carboniferous Limestone age.
(*a*) *Lepidodendron Beds*.—Shales and sandstones, with Carboniferous plants (*Cycloptoris*, *Knorria*, *Sigillaria*, *Lepidodendron*) resting unconformably in Devonian beds.	(*a*) Calciferous Grit Series.

Though Prof. M'Coy considers, on palæontological grounds, that the upper beds of the above series may be of Mesozoic age, we are unable to concur in that view, and consider Mr. Clarke's demonstration of their Palæozoic age conclusive. The whole series, with the exception of the Wianamatta shales, are conformable throughout, and the differences in the flora and fauna between the Upper and Lower series are not greater than those between the Upper and Lower Carboniferous beds of Great Britain.

The quantity of coal raised in 1874 amounted to 1,304,567 tons, and the returns of the out-put since 1829 show a steady annual increase. The demand in the future is likely to exceed the supply; but collieries are being rapidly opened up where means of transport to the markets are available.

Amongst the most valuable products of the coal-fields are the "Kerosine shales," a kind of oil-shale or cannel, of which 96,141 tons were raised in 1874 from three mines. These beds resemble the oil-cannel of Torbane Hill in Scotland, and the associated shales from which the celebrated paraffin oil is extracted. Some of these seams are exceedingly rich, and are used for the production both of petroleum and gas. Beds of clay-ironstone, besides large veins and masses of brown hæmatite, occur towards the base of the Carboniferous rocks in several places, amongst which those of Wallerawang are likely to become of the highest importance. A detailed account of the various ores has been drawn up by Prof. Liversidge, accompanied by chemical analyses, which show that the ores are rich, containing from 40 to 56 per cent. of metallic iron. Other iron-producing works have been established at Lithgow Valley and Berrinia, but space forbids fuller reference. For the accounts of the gold, silver, and precious stones, including the diamonds of Inverell and Armidale, we must refer to the pages of the book itself, which, though full from cover to cover of valuable information, suffers much from the want of a good index.

OUR BOOK SHELF

Geological Sketches. By L. Agassiz. Second Series. 8vo. pp. 229. (Boston, James R. Osgood and Co.; London, Trübner. 1876.)

No better idea can be given of this little book than is obtained from the first few words of the preface. "This edition of the 'Geological Sketches' offers nothing new to the public. Taken in connection with the former one, it only presents in a permanent form and in their original sequence all the geological and glacial papers contributed by Prof. Agassiz to the *Atlantic Monthly* during a number of years." It consists, in fact, of five chatty papers on glacial phenomena in various parts of the world, written in that kind of personal manner that makes them read like a book of travels or a chapter of an autobiography. It is perhaps chiefly from this latter point of view that this collection is interesting. Whatever may be Agassiz's position with respect to the interpretation of the phenomena of recent glaciers, there can be no question but that to him is due the first recognition of their former existence and extent in this country and elsewhere where they now no longer exist. From the day of that discovery in 1840, "Glacial Geology," now a department by itself, has been steadily growing, till investigations into the work of ice has been carried into almost every part of the globe, not excluding the Tropics. Agassiz has therefore a fair right to the title of Father of Glacial Geology. He gives us here an interesting sketch of his first opening up this ground by his visit to Scotland, and puts in a popular

form his theory of the formation of the parallel roads of Glen Roy. We have a glimpse of his well-known tone of thought in the question which he says, in one of these essays, one *naturally* asks, "What was the use of this great engine set at work ages ago to grind, furrow, and knead over, as it were, the surface of the earth?" and finds as an answer that it was a special provision for making the surface fertile by ploughing it deeply and preparing it as a grain-growing soil. Perhaps we could not have a better justification for calling teleological arguments "barren virgins," with Prof. Huxley, than this instance, for if the glacial period were a special provision for the wants of man, we should be cut off from the conclusions, now almost proved by evidence, first that man existed in these isles *before* the glacial epoch, and second, that this epoch should rather be called the *last* glacial epoch, as there have been similar ones throughout geologic time. This last conclusion, involving the extension of glacial conditions through a long range of time, at various intervals, a conclusion largely due to Prof. Ramsay, will be only second in importance, when fully established to its extension in space so conclusively proved by Agassiz and others. The longest of the five papers in this collection is the most recent: "On the Physical History of the Valley of the Amazons," in which he gives his reasons for considering the whole of that valley to have been filled with ice, and to have extended much further to the east at that period. This is scarcely the place for discussing conclusions that have been made known in a larger work with the evidence stated; but we may call attention to the fact that no furrows, striæ, or polished surfaces are anywhere to be found there, and the evidence, therefore, is not of that positive character that so remarkable a conclusion would seem to demand. The country is so little known that at any time fresh observations might modify any conclusion drawn from negative or secondary evidence.

To the Victoria Falls of the Zambesi. Translated from the Original German of Edw. Mohr. By N. D'Anvers. (London: Sampson Low and Co., 1876.)

IN noticing the German edition of this work (NATURE, vol. xii. p. 231) we said that it was well worth translating into English, and we are therefore glad to see that Messrs. Low and Co. have put it within reach of the English reading public. The work is full of interest, and is a really valuable contribution to our knowledge of the region traversed—from D'Urban to the Victoria Falls of the Zambesi. Mr. D'Anvers has done his work of translating very satisfactorily, judiciously omitting a few passages which deal with matter already brought before English readers. All the original illustrations seem to have been retained, including the brilliant but tasteful chromo-lithographs. A new route-map, on a larger scale than the one in the German edition, has been constructed for this translation.

Sport in Abyssinia, on the Mareb and Tackazzee. By the Earl of Mayo. (London: John Murray, 1876.)

THE Earl of Mayo seems to have published this book to show intending sportsmen in Abyssinia how not to do it. His expedition, organised solely for sport, was rather an unfortunate one. Very little sport was obtained by the author, and ere he had well set to work, he was taken so ill that he had suddenly to return to Massowah to catch a homeward-bound steamer. The work contains some shrewd observations on Abyssinian people and affairs, and will no doubt be appreciated by sportsmen.

Health in the House. By Catherine M. Buckton, Member of the Leeds School Board. Sixth edition. (London: Longmans and Co.)

THIS useful book consists of twenty-five lectures on Elementary Physiology in its application to the daily wants of Man and Animals, delivered to the wives and children of working-men in Leeds and Saltaire. It will be found a great help to national schoolmasters and others engaged in education, who may desire to give their pupils clear ideas of the structure and life of man, together with a practical knowledge of the necessity of fresh air and cleanliness in their daily life. At the end of the book will be found questions on some of the lectures, a list of works useful for preparing lectures, and tables of foods most suitable for health.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Corrections in the Address of the President of the Royal Microscopical Society (Vol. xiii. p. 332)

BY some unaccountable oversight in copying out the data for calculating the number of molecules of liquid water, the factor expressing the specific gravity of the vapour of water was omitted, and afterwards overlooked. The number of atoms of a gas should really be multiplied by $\frac{8}{9} \times 770 \times \frac{1}{\cdot 6239} \times \frac{1}{2} = 617$. But moreover, on reflecting on the relative reliability of the determinations by the various authors of the number of the atoms in gases, it appears that in taking the mean, greater weight ought to be allowed to that by Clerk-Maxwell, since founded on more recent and accurate data. If his results be considered as of equal value to those of Storey and Thomson combined, the mean would be reduced to so nearly the same extent as the molecules of liquid water would be increased by the above-named correction, that the numbers given in the address may be considered to be as good an approximation to the truth as can be determined in the present state of the question, and none of the general conclusions need be modified. H. C. SORBY

Vivisection

I HOPE that you will permit me to call attention to a passage in the "Statement of the Society for the Protection of Animals liable to Vivisection on the Report of the Royal Commission on Vivisection" (published by the Society, 1, Victoria Street, Westminster). Under the heading "Extracts of Evidence on Extension of the Practice of Vivisection, and Abuses connected therewith," the following words occur (p. 22):—

"Dr. Crichton Brown describes:

"Forty-six animals sacrificed in trying if chloral were antagonistic to pycrotoxine. Cases of poisoning by pycrotoxine are of very rare occurrence. Twenty-nine animals used in Ferrier's series."

I will leave your readers to judge of the kind of impression which this passage tends to give; I will only ask, is it in accordance with the ordinary principles of justice that the following important details (also gathered from Dr. Crichton Brown's evidence) should be entirely omitted by the compilers of the Statement?

1. "Pycrotoxine is sold in large quantities as Barber's poisoned wheat for the destruction of birds" (3218). Concealed in an edible substance, this poison must therefore pass largely through the hands of an ignorant and careless class of persons.

2. Dr. Crichton Brown "succeeded in proving that after a poisonous dose of pycrotoxine has been given to an animal, if a dose of chloral be given subsequently the animal will recover" (3163).

3. The operation to which the animals sacrificed were subjected "consisted in the introduction under the skin of a little fluid by means of a perforated needle . . . . the pain is infinitesimal" (3218).

4. The after effects are convulsions and death, and "convulsions themselves are not necessarily painful" (3218). This is proved by direct and distinct evidence.

5. In consequence of the use made of Barber's poisoned wheat, "numbers of animals die of it in convulsions every year" (3218). It is almost incredible that a course of action which may result in saving human life should be mentioned in the manner above quoted; while a course of action identical as far as the ultimate effect on the animals is concerned, in which

there is no question of saving life, and which is repeated a thousand times for the private benefit of its performers, is omitted!

6. In Dr. Ferrier's research, anæsthetics were so "carefully and liberally given," that five animals out of the twenty-nine sacrificed "died before they were touched or operated on in any way" (3178). FRANCIS DARWIN

Down, Beckenham

The Use of the Words "Weight" and "Mass"

IN a letter with the above heading published in NATURE, vol. xiii. p. 325, Mr. Bottomley has recommended that the ambiguity of the word weight shall be avoided by using the phrase "the gravity of a pound" when we mean the downward force due to the earth's attraction upon a pound weight.

The ambiguity against which Mr. Bottomley wishes to guard is a very real one. Not to speak of common usage, which allows three meanings of the word weight to be loosely intermingled, we have two of these meanings adopted into scientific nomenclature. The universal practice in chemistry is to employ the word weight to signify mass, and anyone may satisfy himself that this use of the word could not be dispensed with in that science by making the attempt to substitute other forms of expression for the convenient words weight, heavy, light, heavier, lighter, as used by chemists. On the other hand, physicists have generally employed the term to signify a force, and the best writers on mechanics are careful to avoid using it to express mass.

But I fear Mr. Bottomley's remedy, if adopted, would introduce quite as serious, perhaps a more serious, ambiguity. Gravity is an acceleration. When we say that gravity is less in a balloon or in a mine than at the surface of the earth, or greater at Glasgow than at Manchester, we are speaking of alterations of g—the acceleration due to the earth's attraction; and it would create confusion to employ this word to designate forces also.

But a practice which I adopted in lecturing on mechanics in Queen's College, Galway, many-years ago seems to meet the difficulty, and may perhaps recommend itself to other teachers. It is to use the word *gravitation* in the proposed sense.

If this were done, *gravity* at Glasgow would mean an acceleration; the *gravitation* of a kilogramme there would be a force; and *weight* would continue a word of doubtful import, to be judged of by the context, sometimes used for a force, sometimes for a mass, and sometimes for those pieces of metal which are employed as measures in weighing (as in the phrases "a set of weights," "a gramme weight"). In further support of my suggestion, it may be observed that the proposed use of the substantive *gravitation* follows legitimately in the English language from the established meaning of its correlative, the verb *gravitate*.

I would wish to take this opportunity of also recommending a prefix which I have found of the utmost service both to students by assisting them to acquire clear conceptions with ease, and to myself. We use the prefix *hyper* placed before the name of any metrical weight, as hyper decigramme, hyper-gramme, hyper-hektogramme. hyper-kilogramme, hyper-tonne, to indicate those forces of the absolute metrical series which are slightly larger in amount (about 2 per cent. more) than the gravitation at the earth's surface of the decigramme, gramme, hektogramme, &c., respectively.

When a student has to use weights as forces, as he must in the laboratory, he should be trained from the beginning to think of them in their relation to the neighbouring absolute forces. For instance, if he uses a hektogramme to exert a pressure, he should be encouraged to think of it rather as $\frac{g}{10}$ths of a hyper-hektogramme (which is a force) than as a hektogramme (which is more properly a mass). This will also keep prominently before his mind that the amount of the pressure depends on the station at which the experiment is made. G. JOHNSTONE STONEY

Queen's University, Ireland, March 9

MR. BOTTOMLEY remarks in his letter on weight and mass that appeared in NATURE, vol. xiii. p. 325, that "During the present session we have aided ourselves in Glasgow with four very important helps to the teaching of the kinetic system of force-measurement. . . . The third help is the construction by Prof. Thomson, for the first time so far as I know, of spring balances for indicating poundals and kilodynes."

Will you permit me to point out that about three years ago Prof. Ball, when introducing the C. G. S. system of units into the course of mechanics at this college, had a series of dynamometers in absolute measure specially constructed by Messrs. Salter, of West Bromwich. These dynamometers were exhibited at the Bradford meeting of the British Association, and will also be seen at the forthcoming Loan Exhibition at the South Kensington. W. F. BARRETT

Royal College of Science, Dublin

Metachromism

MR. FLINDERS PETRIE in his interesting letter (vol. xiii. p. 348) criticises the abstract of my paper which appeared in NATURE some weeks ago. Before considering his communication, I would remark that my argument against Schönbein's theory accounting for metachromism is based upon the colour relation which he mentions. I gave a small table of anhydrous binary compounds which conform to the rule, and that table includes the chlorides of chromium which Mr. Petrie has pushed out into the cold. The relation is thus referred to:—"Those compounds in a series which show the highest amount of the basylous element have the most refrangible colours." So far as I am aware, it is there announced for the first time.

For the sake of clearness we will first examine Mr. Petrie's proposition:—"Increase of the electro-negative element produces a colour-change towards the red end of the spectrum, and *vice versâ*."

Increase of the electro-negative element is *accompanied* by less refrangible colours, but to say that this increase *produces* the change is going farther than the observations warrant, is, in short, opposed to fact. For example, if we take the series of oxides of chromium which he gives—Cr_2O_3 green, CrO_2 yellow green, CrO_3 red, I fail to see that increase of the electro-negative element, *i.e.*, *colourless* oxygen *produces* a change towards the red end, or, on the contrary, that decrease in the positive element does the same. The facts seem rather to show that colour in any body is dependent upon the proximity of its molecules, since we find bodies which, with like chemical composition but different densities, have different hues.

The metachromatic scale given on page 298 is not intended to be absolute, and may, in fact, need a little modification with the accession of more knowledge. But certainly Mr. Petrie's remarks do not affect it, because (1), the colour gradation he refers to is attended by chemical differences, whereas in metachromatic phenomena we have purely physical alterations; (2) white does not come between yellow and blue, either in the "natural" or in the metachromatic arrangement. For if by "natural arrangement" he means that of the pure spectrum, then green is what intervenes between blue and yellow, and white has its nearest counterpart in the ultra-violet grey. Quite recently this part of the spectrum has been termed "silvery grey" by M. Sauer. Independently of this, however, I was led to place white in the ultra-violet part of the metachromatic scale by certain mineralogical facts which I shall not trouble your readers with detailing here.

The assertion, then, that white comes between yellow and blue, would seem to rest upon the colour relation found to obtain between the oxides of the alkali metals, which really is not worth much, because of the little we know about the sub-oxides; and because even the chief series he gives, that of sodium, is an exception to the rule, Na_2O_2 being pure white (Watt's "Dictionary," vol. v., p. 340), and not orange, as Mr. Petrie states; and, finally, because we cannot fairly compare the order of colour we see in the binary compounds with what we get in metachromatic phenomena, although to a great extent there is a colour parallelism which is remarkable. The U.S. Survey Publications

IN NATURE, vol. xiii. p. 314, I observed a note upon the rumour that the publication of Prof. Hayden's Geological Reports was likely to be stopped by the U.S. Government.

Having brought the paragraph under the notice of the Museum Committee of the Town Council, I am requested by them to communicate with you, and to say that several of these Reports have been received by the Leicester Museum, and are regarded as of great value; and that the Museum Committee will be glad

to co-operate in any proceeding which may be thought most likely to induce the Government of the United States to continue the publication of them.

FREDK. T. MOTT

Town Museum, Leicester, March 7

Origin of the Screw Propeller

I SHOULD like to remark, in reference to last week's letter on the origin of the screw propeller, that I have long considered the pectoral fins, which are so extremely useful to and prominent upon soles, or the family *Pleuronectidæ*, as being highly suggestive of this more modern mode of propulsion. Anyone who likes to watch these extremely interesting fish in their swimming movements and graceful gyrations may witness the action and I think attribute to its movements more than is possible in the case of ash and other seed vessels.

WILLIAM EARLEY

The Three Kingdoms of Nature

IN reply to your correspondent's question as to which of the three kingdoms "water" belongs, I beg to state that the strict scientific definition of a mineral, adopted in most mineralogies, is as follows: a mineral is any *inorganic, homogeneous, natural* substance.

This definition obviously includes water, which is accordingly always described in books on mineralogy; and the fact of water being a liquid at ordinary temperatures cannot of course exclude it from the list of minerals. Indeed, in some mineralogies, gases—such as carbonic acid, sulphurous acid, and even the air—are described as minerals. Water, like many other minerals, can exist in more than one form; thus, if the temperature of our globe were much lower than it is, we should only have water in the form of the transparent crystalline solid, known as ice, which—like other minerals, such as sulphur, metallic lead, metallic mercury, &c.—has its own particular point of fusion; thus: sulphur melts at 226° F., water at 32°, mercury at 39°. All these substances still further resemble one another in their capability of being converted into a gaseous form, at certain fixed temperatures. These facts—with many others—prove water to be as much a mineral as calcite or gypsum.

VITA BREVIS

OUR ASTRONOMICAL COLUMN

COMET 1840 (II.).—In *Astronomische Nachrichten*, No. 2,079, Dr. Kowalczyk, of Warsaw, publishes his investigation of a definitive orbit for the comet discovered at Berlin, by Prof. Galle, the present Director of the Observatory at Breslau, on the 25th of January, 1840. This comet, which was last observed at Kremsmunster on the 1st of April, had already been made the subject of extensive calculation by Professors Plantamour and Loomis. The former, in 1843, discussing his own series of careful observations taken at Geneva, found (*Astron. Nach.*, No. 476) that a parabolic orbit represented the comet's course within the probable limits of error of observation; on including the series taken at Berlin he found the most probable orbit to be an ellipse, but of great excentricity to which little weight was considered to attach. Loomis, on his side, taking into account the effect of planetary perturbation during the interval of the comet's visibility, also found an ellipse, but with a more moderate excentricity, the period of revolution being about 2,420 years; the sum of the squares of the errors in the ellipse is diminished to one-third of the amount with the best determinable parabola. Loomis's investigation will be found in the "Transactions of the American Academy," vol. viii.; his orbits are not included in the extensive collection in Dr. Carl's "Repertorium der Cometen-Astronomie," a work which, notwithstanding its great utility to the student of this branch of the science, is yet not complete or free from numerical errors.

Kowalczyk starts with the parabolic elements obtained by Plantamour in 1843, comparing them with the whole course of observations. After introducing the corrections for aberration and parallax, and the earth's positions from Leverrier's tables, instead of those from the Tables of Carlini used by previous computers and by the usual method of equations of condition for ten normal places, he finally arrives at an elliptical orbit, very closely agreeing with observation, and showing a period of revolution of 3,789 years.

BERLINER ASTRONOMISCHES JAHRBUCH, 1878.—The Berlin Ephemeris for 1878 has been received during the past week. In its speciality—the ephemerides of the minor planets—Prof. Tietjen has evidently made a very vigorous and successful effort to keep pace with the frequent additions to the list; his volume contains approximate places for every twentieth day during the *present* year of 144 of the 160 small planets hitherto detected, and accurate opposition ephemerides of 71, occupying together one-third of the entire work. The collective table of elements to No. 147 inclusive is not the least important part of this volume of the *Jahrbuch*.

Prof. Tietjen continues to transfer to the Berlin work—of course after reduction to that meridian—the places of the moon from our *Nautical Almanac*, which, by order of the Admiralty, is invariably published three complete years in advance of that to which it applies, and considerably earlier than any other of the national ephemerides. The economy of labour of computation thereby effected, which is probably found by the conductor of the *Berliner Jahrbuch* of material assistance for the production of his extensive work on the minor planets, might possibly be extended in other directions. An ephemeris of the moon from Hansen's Tables, employed for all the European ephemerides, admits of pretty complete check at a small expense of calculation, and there appears to be no advantage derivable from an independent work involving such heavy labour as the computation of the moon's positions through a whole year. Prof. Tietjen contents himself with a few direct calculations from the Tables which he says "invariably exhibit a satisfactory agreement" with the results in the *Nautical Almanac*.

PHYSICAL SCIENCE IN SCHOOLS

WHEN I claimed for science a position of educational equality "both as regards *range and time* with classics and mathematics," I intended to express the *amount* of science teaching in the school curriculum which alone can satisfy the upholders of a scientific education. I am as fully aware as Mr. Wilson is of the

[1] N.B.—This is $\frac{1}{10}$ lower than I ever saw it before.

importance of a firm mathematical foundation, and I am as far from wishing to overwhelm the younger boys with science before they have mastered the elements of arithmetic and grammar and languages as he can be. My experience amongst boys has, however, not been such as to enable me to say exactly when a thorough science teaching ought to begin.

The mistake, as it seems to me, which is prevalent respecting science teaching in schools, is the notion that it is a subject to be *lectured* upon for two hours per week to those already educated, and who show an aptitude for it, whilst it can, and ought to, be introduced at a definite period as a regular part of *school work*. It is now usually made an extra subject, a quasi-amusement, put on the same footing as drilling or drawing, whilst it can, and ought to, be made as much a discipline as the Latin grammar or Euclid, affording, as it does, in my opinion, if properly taught, an excellent training ground for acquiring that reasoning power and habit of application which it is usually supposed can only be gained through one or other of these older channels. I am sorry that Mr. Wilson thinks that any man of science is misleading public opinion on this subject. This is a serious charge, but as it rests on a misconception, I remain convinced that in the long run public opinion will endorse our views.

It is out of my power to tell Mr. Wilson whose business it is to make the change to a better state of things, which he himself feels to be necessary, for he admits that the new examination is adverse to scientific education. I do, however, feel strongly that unless the authorities of our great schools and the examining Boards set earnestly to work to introduce this new discipline and give it (as many of them to their honour are now beginning to do) a fair field and no favour, the beneficial influence which these schools have had on English education, must soon begin to diminish.

The Balliol scholarships and the other great University "advertisements" I believe to be in many ways stumbling-blocks in the path of true education in this country; "the many," as Mr. Wilson truly says, "are kept to swell the triumph of the few," and the prizes have to be got "at any cost to boy or school." Are we never to break loose from this degrading bondage to the Moloch of examination? I for one think better both of commissioners, governors, and head-masters, and look forward with hope to the ultimate emancipation of school-boys from their ancient fetters. Then those subjects will be taught at school which are best suited to make the mass of boys good citizens, and to forward the highest interests of the country, instead of the great aim of the schoolmaster being to secure a Balliol scholarship. We shall then see less than we do now of University men taking to sheep-farming in Australia, and hear less complaint of the superiority of our continental friends both in pure science and its application. HENRY E. ROSCOE

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA[1]

IV.

IT was mentioned in the last lecture that no true Proboscideans have been found below the Miocene strata, but among the most remarkable of the numerous recent discoveries in the Eocene formations of Wyoming Territory, North America, has been that of a group of animals of huge size, approaching, if not equalling, that of the largest existing elephants, presenting a combination of characters quite unlike those known among either recent or extinct creatures, and of which there were evidently several species living contemporaneously. To form some idea of their appearance, we must imagine animals very elephantine in their general proportions, elevated on massive pillar-like limbs, with the same complete radius and ulna, the same short, round, five-toed feet which distinguish the elephants from all other known hoofed quadrupeds. The tail, as in the elephants, was long and slender, but the neck, though still short was not so much abbreviated as in modern Proboscideans, and there is no good evidence of their having possessed a trunk. The brain was exceedingly small for the size of the creature. The head differed greatly from that of the elephants, being long and narrow, more like that of a rhinoceros, and, as in that animal, was elevated behind into a great occipital crest, but unlike that or any other known mammal, it had developed from its upper surface, three pairs of conspicuous laterally diverging protuberances, one pair from the parietal region, one over or in front of the orbits, and one near the forepart of the elongated nasal bones. Whether these were merely covered by bosses of callous skin, as the rounded form and ruggedness of their extremities would indicate, or whether they formed the bases of attachments for horns of still greater extent, either like those of the rhinoceros or the cavicorn ruminants, must still be a matter of conjecture. But in either case they must have given a very strange aspect to the creature which possessed them, and have been formidable weapons in encounters either with animals of its own kind, or with the fierce carnivorous beasts whose remains are associated in the same deposits with them. There were no incisor teeth in the upper jaw, but a pair of huge descending canine tusks very similar in position and form to those of the musk-deer. Behind these, and at some distance from them, were, on each side above and below, six molar teeth of comparatively small size, placed in continuous series, each with a pair of oblique ridges, conjoined internally, and diverging externally in a V-like manner, and with a stout basal cingulum. The lower incisors and canines were small, and are only known at present by their sockets. The dental formula is—

$$i\,\frac{0}{3}\,c\,\frac{1}{1}\,p\,\frac{3}{3}\,m\,\frac{3}{3} = 34.$$

The first discovered evidences of the existence of animals of this group were described by Leidy in 1872, under the name of *Uintatherium*, from the Uintah Mountains, at the base of which they were found. Very shortly afterwards other portions of bones and teeth of either the same or closely allied forms, were described by Marsh as *Dinoceras*, and by Cope as *Loxolophodon* and *Eobasileus*. Whether these names will ultimately be retained for separate generic modifications, or whether they will have to be merged into the first, it would be premature to attempt to decide upon the evidence before us. A more important question is, what are the affinities of the animals, and what light do they throw on the general evolutionary history of the class to which they belong? Looking at the totality of their organisation as already known, at first sight they seem to present a considerable resemblance with the Proboscidea. The absence of the third trochanter, and of the fossa for the ligamentum teres on the femur, and the general form of the feet with their short broad toes are quite Proboscidean characters, but a closer examination of the structure of the carpus and tarsus, especially of the mode of union of the different bones with each other, shows more essential affinities with Rhinoceros. The same may be said of the cranium, so that on the whole they appear to come nearer to the Perissodactyle Ungulates than was formerly supposed. This relationship is strengthened by the discovery of other forms, constituting the genera *Bathmodon* and *Metalophodon* of Cope, of earlier geological age, which with the same general structure of the *Uintatheriidæ* retain in a most interesting manner many primitive characters, especially the complete number of incisor and premolar

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.) Continued from p. 356.

teeth. These are forms for fuller information upon which we anxiously wait.

The negative evidence (which of course must be received with the greatest caution in palæontology) of the absence of remains of any of these animals in the true Miocene or Pliocene deposits of North America, indicates that the race became extinct at least in that land, though it possibly may have emigrated elsewhere, and perhaps in Asia, may have laid the foundation of that family which first appears in the Old World under the more familiar aspect of typical Proboscideans. While, however, there are no grounds for assuming that the latter were derived directly from the Eocene Bathmodons and Uintatheriums, it is not too much to look upon these as affording some indications of the steps by which the process might have taken place, and, as such, their discovery is one of the most interesting that has been revealed by modern palæontological research.

It should be mentioned that Marsh, who has given us very full information upon the osteology and dentition of this group, has made of *Uintatherium* and its immediate allies a peculiar order of mammals, to which he gives the name of *Dinocerata*, while Cope, who formerly included them in the Proboscidea, and placed *Bathmodon* and its allies in the Perissodactyla, has recently formed an order called *Amblypoda*, containing two sub-orders, of which *Dinocerata* is one, and *Pantodonta* (*Bathmodon* and *Metalophodon*) the other.

The tertiaries of South America have yielded some very remarkable forms of mammalian life, the nature and affinities of which have greatly puzzled all zoologists who have attempted to unravel them. *Macrauchenia* has been already described among the Perissodactyle Ungulates, of which group it is undoubtedly a member, although in some characters somewhat aberrant. The articulation of the fibula with the calcaneum is an Artiodactyle, or perhaps generalised character. The teeth ally it to Palæotherium and Rhinoceros. *Homalodontotherium* from the banks of the River Gallegos, South-east Patagonia, is known by the teeth alone, which, though very generalised, are on the whole rhinocerotic. *Nesodon*, from the same locality, also only known by the dentition and some parts of the skull, connects the last and *Macrauchenia* with *Toxodon*. These three genera have the typical dental formula of $i\,\frac{3}{3}\,c\,\frac{1}{1}\,p\,\frac{4}{4}\,m\,\frac{3}{3} = 44.$ *Toxodon* is an animal about the size of a hippopotamus, of which many specimens have now been found in Pleistocene deposits near Buenos Ayres, which have been described by Owen, Gervais, and Burmeister. The teeth consist of incisors, very small lower canines, and strongly curved molars, all with persistent roots; the formula being apparently $i\,\frac{2}{3}\,c\,\frac{0}{1}\,p\,\frac{4}{3}\,m\,\frac{3}{3} = 38$. The cranial characters exhibited a combination of those found in both Perissodactyles and Artiodactyles, but the form of the hinder part of the palate, the absence of an alisphenoid canal, and especially the tympanic being firmly fixed in between the squamosal and the exoccipital, ankylosed to both, and forming the floor of a long, upward directed meatus auditorius, is so exactly like that of the *Suina*, that it is difficult to believe that it does not indicate some real affinity to that group. These characters seem to outweigh in importance those by which some zoologists have linked it to the Perissodactyla, and the absence of the third trochanter, and the articulation of the fibula with the calcaneum tell in the same direction. The structure of the feet is not known, but it is probable that it had five toes on each.

Mesotherium, Serres, also called *Typotherium* by Bravard and Gervais, was an animal rather larger than a Capybara, and of much the same general appearance. Its skeleton is completely known, and shows a singular combination of characters, resembling Toxodon, or a generalised Ungulate on the one hand, and the Rodents, especially the *Leporidæ* on the other. In the presence of clavicles, of five toes on the fore-foot and four on the hinder, it differs from all existing Ungulates, and yet if it is considered as a Rodent, it must be looked upon as a most aberrant form. The teeth are $i\,\frac{1}{2}\,c\,\frac{0}{0}\,p\,\frac{2}{1}\,m\,\frac{3}{3} = 24.$ Although our knowledge of many of these forms is still very limited, we may trace among them a curious chain of affinities, which, if correctly interpreted, would seem to unite the Ungulates on the one hand, with the Rodents on the other; but further materials are needed before we can establish with certainty so important a relationship, one which, if true, would alter materially some of the prevailing views upon the classification of mammals. It may be convenient provisionally to include those Ungulates which are neither *Artiodactyla* nor *Perissodactyla*, under a third heading, of which *Polydactyla*[1] would be the appropriate designation; though there is no evidence that they form such a homogeneous group as either of the other two.

(*To be continued.*)

PROF. HUXLEY'S LECTURES ON THE EVIDENCE AS TO THE ORIGIN OF EXISTING VERTEBRATE ANIMALS[2]

I.

TWENTY years ago the arguments as to the causes of the phenomena of organic nature, brought forward in support of the then recently advanced views of Mr. Darwin, were largely speculative; all one could hope to show was that no valid objections could be urged against the theory of evolution. But since that time "many have run to and fro and knowledge has been increased"; the question has come out of the region of speculation into that of proof; every day increases our familiarity with the phenomena of life on the globe in antecedent ages, and so gives us the only valid evidence obtainable as to the evolution of living things.

When we consider any animal at the present day there are three hypotheses which may be put forward with regard to its origin: that it arose out of nothing, that it had its origin from dead inorganic matter, or that it arose as a modification of some pre-existing living being. It is hardly worth while to consider the two first of these hypotheses—for the first it would be utterly impossible to obtain any evidence, and the second is devoid of all ground of analogy, and opposed to all our knowledge of what actually takes place. The last, on the other hand, should, if true, be capable of some sort of proof—at any rate it can be brought to the test of facts.

It is quite conceivable that all evidence as to the origin of an animal may have disappeared, and that the problem becomes, in consequence, insoluble by direct evidence, analogy and probability being the only guides left. As a matter of fact, however, we possess in the 70,000 feet of stone, gravel, sand, &c., which form the earth's crust, fossil remains imbedded in chronological order, and in many cases so perfectly preserved, that all important details can be made out almost as well as in the recent state.

The plan adopted in these lectures will be not to give all obtainable evidence with regard to the origin of each group of vertebrate animals, but to select from each class one or two definite cases of living animals, and to see what evidences can be obtained, by going back in time, as to the way in which they have come about, or at any rate as to the extent of the duration of their existence.

[1] An extension of the order *Toxodontia* of Owen, and *Ungulata multidigitata* of Burmeister.

[2] A course of six lectures to working men, delivered in the theatre of the Royal School of Mines. Lecture I., Feb. 28.

To begin with fishes: we will take as our first example the very beautiful genus Beryx, a fish not unlike our sea-bream, found widely distributed through the deep seas, and extending to about 40° on each side of the equator. Like the perch or the sea-bream, it is a greatly *specialised* fish; the head is immensely large, the bony rays supporting the fins hard and unjointed, the ventral fins or representatives of the hind limbs situated just behind the head, under the throat, the operculum curiously ornamented, and the air-bladder completely shut off from the gullet; thus differing very markedly from a more *generalised* fish such as the herring or carp, in which the head is proportionally much smaller, the fin-rays soft and jointed, the ventral fins far back, the operculum not ornamented, and the air-bladder communicating by a duct with the œsophagus.

We now know that at depths greater than five or six hundred fathoms, the sea-bottom is to a great extent composed of a very fine greyish-white mud, sticky when first removed from the water, but afterwards hardening into a delicate friable stone, not at all unlike chalk. This mud, which is largely made up of shells of the minute marine organism *Globigerina*, forms the bed of thousands of square miles of sea in which Beryx lives, and there can be no doubt that when the fish dies it sinks to the bottom, and, its soft parts being destroyed, becomes gradually imbedded in the soft mud, there to remain until the present sea-bottom is upheaved and becomes dry land.

Now, as a matter of archæological evidence, what is known of the history of Beryx and of the source whence it proceeded? Naturally it is useless to seek for such evidence except in deposits formed under like conditions to those in which the fish lives at the present day. Through the whole of the Pliocene and Miocene epochs no deep-sea formations are known, but in the middle of the Eocene period—a time so remote that tropical plants flourished on the banks of the Thames, and crocodiles abounded in this country—we are acquainted with an extensive deep-sea deposit, the Nummulitic limestone, which, besides the fossil giving it its name, contains large quantities of Globigerina, in all essential respects like that of the present day. In this formation are found two forms closely allied to Beryx, but with such slight differences as to receive different generic names; these are known as Acanus and Pristigaster. On passing from the Eocene or lowest tertiary to the chalk or uppermost secondary formation, which bears the closest possible resemblance to the modern Atlantic mud—the two may, in fact, be looked upon as belonging to one continuous series of deposits—we find an actual Beryx, a fish differing no more from the modern Berices than the various modern species of Beryx do from one another. This fossil, owing to the fineness of the chalk-forming mud in which it was buried, is so perfectly preserved, that all the details of structure of its hard parts, even to the ornamentation of the scales, can be compared with those in the recent fish; and in this way the most conclusive evidence is obtained that the differences which separate it from its modern relatives are of no greater importance than those by which the recent species of Beryx are distinguished from one another.

Thus we have positive evidence that a fish altogether like the Beryx of the present day, existed millions of years ago, before the Alps, the Himalayas, or the Rocky Mountains were upheaved, and has continued to live ever since. In face of these facts we cannot but conclude that the modern Beryx is derived from that of the chalk, and that the hypotheses of its creation out of nothing, and of its origin from inorganic matter are, for scientific purposes, simply non-existant.

As to the form from which the Beryx of the chalk was derived, we have absolutely no evidence, for there is no trace of any such fish in any lower formation.

We now pass on to a fish of a far older and less specialised type than Beryx—the genus *Ceratodus*, recently discovered in Australia. This animal, which attains a length of six feet, is distinguished by the possession of very curious fins, consisting of a central lobe, with a surrounding fringe of fin-rays, and by the character of its teeth, which are produced into curious horn-like processes, so arranged that those of opposite jaws interlock. Ceratodus is probably a vegetable feeder, lives in fresh or brackish water, and is said sometimes to leave its native element and crawl about among the weeds on the bank. It is enabled to do this by the fact that it can breathe air directly as well as air dissolved in water; it has, in fact, besides gills, an organ which is altogether a half-way house between the air-bladder of a fish and the lung of an amphibian.

In the Wealden, the most recent estuarine deposit of which we have any knowledge, there is no trace of Ceratodus to be found, but this is hardly surprising, as only two or three small patches of the earth's surface formed at this epoch have been examined, and animals have a geographical distribution at all times. But on passing back to the Trias, a formation as far from the chalk in point of time as the chalk from the present day, we find teeth belonging to an undoubted Ceratodus, in shape and in microscopic structure, exactly like those of the modern Australian fish. No other remains of the Triassic Ceratodus have as yet been found, but teeth are known to be so important a diagnostic character that no naturalist would have any hesitation in naming the genus to which the fish bearing such teeth should be assigned.

Thus we have a far more astonishing example of a persistent type than was afforded by our Beryx, and as in the case of the latter fish, all trace of the actual genus Ceratodus is lost at this point, and we are obliged to content ourselves with a few singular hints as to the way in which the type has come about. The most valuable of these hints are obtained by a study of a singular group of fish found in great abundance in the Old Red Sandstone. These are distinguished by the possession of curious fringed fins, unlike those of any other fish except Lepidosiren and Ceratodus—in fact, one genus, Dipterus, has fins quite like those of Ceratodus, and its teeth and skeleton were formed on just the same type. It is doubtful whether there is any relation between Ceratodus and Dipterus in the way of ancestry, but the resemblance between them is remarkable.

It must seem rather strange for a known evolutionist to select as examples two fish like Beryx and Ceratodus, which, of all others, seem most likely to support the notion that species are immutable. The adverse side only of the question has been stated to-night, the other side will be treated of on future occasions.

THE OLD RED SANDSTONE

At a meeting of the Glasgow Geological Society on the 24th ult., Sir William Thomson, F.R.S., president, in the chair, Prof. Geikie, F.R.S., communicated the results of recent researches into the "History of the Deposits known as the Old Red Sandstone." After a preliminary outline of our present knowledge on the subject, he proceeded to consider the development of the Old Red Sandstone in the British Isles under its accepted threefold division into Lower, Middle, and Upper. The Lower member, wherever its true base can be seen, is found to pass down conformably into the Upper Silurian rocks. But a well-marked line of demarcation, both by physical characters and fossil evidence, runs between the two systems. The Silurian formations continue replete with organic remains up to their uppermost zone; but on entering the red strata of the overlying system we meet with a remarkably abrupt change, for the fossils almost wholly disappear, and those which occur belong for the

most part to fishes and crustaceans. The author pointed out the geological evidence in favour of great terrestrial oscillations as explained by Prof. Ramsay, whereby the bed of the Silurian sea in our area came to be raised into land with wide lakes and inland seas. He showed that the beginnings of the movements which led to those results could be traced back a considerable way into the Silurian period, that over large tracts the Silurian deposits had been upraised before the close of that period, and that the oscillations continued during the accumulation of the Lower Old Red Sandstone, as indicated by the coarse conglomerates, the great mass of the deposits, and the unconformabilities traceable in them. Recent detailed work of the Geological Survey has brought to light the fact that this lower division of the Old Red Sandstone attains an almost incredible thickness. In Lanarkshire and Ayrshire Mr. B. N. Peach has found it to measure 15,000 feet. In Perthshire, from the combined surveys of Mr. Peach and Mr. R. L. Jack, it has been ascertained to reach a depth of more than 19,000 feet. But the author has found that traced eastward into Forfarshire and Kincardineshire, its thickness rises above 20,000 feet. And yet in no case is its top actually seen, since it has either been removed by denudation, or buried under some more recent unconformable formation. Nor is its base to be found, since along the flank of the Grampians a great fault runs from the North Sea at Stonehaven to the estuary of the Clyde, with the effect of throwing the strata of the Old Red Sandstone on end, sometimes for a distance of two miles from the line of the dislocation. The amount of displacement must be in some places not less than 5,000 feet, as indicated by the position of occasional outliers of conglomerate on the Highland side of the fault. One of the most striking features in the formation is the enormous development of its contemporaneous volcanic rocks. These are underlaid in Kincardineshire by about 5,000 feet of sandstones and shales, and they pass under the grey flags and conglomerates of Forfar, and an upper series of red and purple sandstones. They consist of thick sheets of various porphyries with beds of tuff and enormous masses of coarse volcanic conglomerates. Zones of grey flagstones, including the well-known beds of Carmylie near Arbroath, are intercalated in them. In the Ochil Hills, according to the measurements of Mr. B. N. Peach, this volcanic zone reaches a depth of not less than 6,500 feet. It runs from the sea-coast at Dunottar through the chain of the Sidlaw and Ochil Hills to near Stirling. It reappears south of the Forth, in the Pentland chain, and stretches south-westwards in great force across Lanarkshire and Ayrshire. The author then alluded to the fossils hitherto noticed in this part of the Old Red Sandstone in different parts of Britain, pointing out the contrast they present to those of the preceding Silurian rocks. He showed that in Forfarshire the well-known crustaceans and fishes had been obtained from strata, lying not as hitherto supposed at the base of the system, but several thousand feet higher, and that the fish-bed found by Mr. Mitchell in Kincardineshire, and supposed by Sir Roderick Murchison to indicate from its Acanthodian forms an approach to the middle Old Red Sandstone, really lay below the position of the Turin flagstones so well explored by Mr. Powrie.

The so-called "Middle" Old Red Sandstone is not known certainly to exist anywhere else in Britain than in the north of Scotland. This subdivision was introduced by Sir R. Murchison, and is based wholly on the evidence from fossils. It presents a remarkably distinct series of ichthyolites, which have not been met with in the Lower Old Red Sandstone of the south, and which have therefore been held to mark a higher series of deposits. The "Middle" Old Red Sandstone is typically developed in the well-known flags of Caithness. Those strata, long since described by Sedgwick and Murchison, cover nearly the whole of that county, and stretch into the Orkney and Shetland Islands. The author had measured a section of these on the east coast of Caithness more than 8,000 feet in thickness. They show conglomerates and red sandstones at the base, and similar strata reappear on different higher horizons. But on the whole, the series consists of dark-grey, hard, fine-grained flagstones, sometimes bituminous, often calcareous, and frequently abounding in remains of fishes, entomostraca, and land-plants. No evidence of contemporaneous volcanic action has yet been met with in these rocks. The general character of the whole series differs in many respects from that of the Old Red Sandstone on the south side of the Grampians, and appears to indicate widely different conditions of deposit. The basins in which the Caithness flags, and the Arbroath flags accumulated, were separated by the intervening mass of the Inverness-shire and Aberdeenshire highlands, as shown by the basement conglomerates on each side of the mountains. The author then dwelt on the fossil evidence and its bearings. He suggested that it could not be held to prove a "middle" series, and that it was not inconsistent with the idea that the Caithness flags really belonged to the Lower Old Red Sandstone, the peculiarities of their fauna not being greater than might be due to great differences of physical geography, and to the fact that the respective areas of deposit were isolated from each other. He further pointed out that some of the most characteristic forms of the lower group occur in the Caithness and Orkney beds, *e.g.*, *Pteraspis*, and *Pterygotus*. The Caithness flags abound in land-plants like *Sigillaria*, *Lepidodendron*, and some of the peculiar Devonian forms found by Dr. Dawson in Gaspé. Some of these latter forms have recently been detected by Mr. R. L. Jack in the course of the work of the Geological Survey in Perthshire.

The red and yellow sandstones, red clays, and red conglomerates and breccias, included under the term "Upper Old Red Sandstone," are copiously developed in Wales, in Ireland, and in the south of Scotland. In the two last-named regions they have been shown to lie unconformably on all older formations, there being a complete physical discordance, and an entire difference in organic contents, between these strata and the Lower Old Red Sandstone. In South Wales a less marked break in the series may be suspected from the cautious descriptions given by Sir Henry De la Beche. In the north of Scotland Sir R. Murchison has described the Upper as graduating downwards into the Middle or Caithness flags. In Caithness itself, however, and in Orkney, they are completely discordant, and the same relation may be inferred to hold elsewhere. This uppermost member thus bears the same relation to the Caithness flags as to the Arbroath flags. Wherever the top of the series can be seen, it is found to pass gradually and conformably into the base of the Carboniferous system. So thoroughly do these two series of deposits dovetail with each other that no sharp line can be drawn between them. If we work our way into the red rocks from the Carboniferous side, we may claim them as merely the base of the Carboniferous system. If we approach them from the side of the Old Red Sandstone, we may well regard them as a late and unconformable sub-division of this system.

The author next adverted to the fossils peculiar to the Upper Old Red Sandstone, calling attention to the continuance of land-plants and ganoid fishes as characteristic Old Red Sandstone features. He then, in conclusion, pointed out the physical geography which appears to be indicated by the deposits of this period. It is still possible to map out some of the terrestrial and lacustrine areas which then marked the site of Britain. Hill-ranges, still in existence, formed prominent features in the landscapes of that time, though with many differences of outline; in particular, with water-filled bays, straits, long fjord-like inlets and scattered lakes which have been filled

up with sandstones, conglomerates, and breccias. The red stain of these deposits, occasional pseudomorphs of rock-salt and layers of gypsum, combined with ripple-marks and sun-cracks seem, as Prof. Ramsay has suggested, to indicate the concentration of the saline waters which filled these basins; while further evidence of the unwholesome nature of the water may be indicated by the general paucity of fossils in the strata, and by the immense numbers of well-preserved fishes which are sometimes met with crowded into a small space, as if they had come from fresher water elsewhere, and had been inclosed and killed in scattered pools. The peculiar breccias and brecciated conglomerates of the Upper Old Red Sandstone have been compared to some recent Glacial deposits, and the resemblance has been pointed out between the form of the stones in these deposits, and those in common boulder-clay. It should be noted also that in many cases these breccias occur in old valleys, and bear many of the characters of valley-moraines. Such are those to the east of Ullswater, and those which flank, and in some places penetrate the Lammermuir Hills. In the latter district worn dome-shaped bosses of rock underlying the breccias recall the aspect of true *roches moutonnées*. Another glacial feature is suggested by the basin-shaped hollows (apparently sometimes true rock-basins) in which the deposits lie. Further indications of ice are given by the remarkable patches of angular and rounded stones scattered through the red sandstones of Arran, the occurrence and position of which may be accounted for on the supposition that they are portions of shore-gravel, which have been frozen and transported in cakes of floating-ice.

Indications of terrestrial disturbance during the accumulation of the Upper Old Red Sandstone in Scotland are furnished by the Lammermuir Hills. Towards the close of the period, and thence through the deposition of the Lower Carboniferous rocks, volcanic action which seems to have been quiescent for a long interval, broke out again over the south of Scotland. To this period belongs the chain of old lavas and tuffs which may be traced from the mouth of the Nith eastwards by Langholm and the Tarras Water, to the head of the Slitrig Valley, and through the plain of the Tweed as far northwards as the Whiteadder. The Garlton Hills, Campsie Fells, and the ranges of hills which run down Renfrewshire and the north-east of Ayrshire, and are prolonged into Bute, the Cumbrays and Arran mark a prolonged series of volcanic eruptions during this same period. Probably the terraced hills of Lorne are of similar age. Traces of contemporaneous volcanic action occur likewise in the Upper Old Red Sandstone of the north of Scotland, and form a remarkable feature in the cliffs of Hoy, one of the Orkney Islands.

The author brought forward evidence to show that while the Upper Old Red Sandstone was being deposited in the British area, there existed outside that area a sea in which some of the characteristic corals, brachiopods, and other organisms of the time of the Carboniferous Limestone already existed. He pointed out the intercalation of limestone bands in the Red Sandstone series in Arran and elsewhere, a long way below the base of the Cementstone group which underlies the Carboniferous Limestone. These calcareous bands, full of species of fossils which are familiar in the Carboniferous Limestone, seem to indicate that while, on the whole, the Upper Old Red Sandstone, and the red strata at the base of the Carboniferous system were deposited under conditions unfavourable to the presence of at least corals, crinoids, and molluscs, their formation was interrupted by intervals during which clearer and less saline water prevailed, perhaps owing to the removal of barriers which allowed the access of the main ocean with its animal forms into the closed lagoons and inland seas of the Upper Old Red Sandstone.

ON REPULSION RESULTING FROM RADIATION[1]

THIS paper contains an account of experiments on the action of radiation on bodies the surfaces of which have their radiating and absorbing powers modified by various coatings. The difference between a white and a lamp-blacked surface in this respect was at first not very decided, and experiments have been instituted with the object of clearing up some anomalies in the actions observed. Two pith discs, one white and the other black, are suspended on a light arm in a glass bulb by means of a fine silk fibre; after perfect exhaustion the white and black discs are found to be equally repelled by heat of low intensity, such as from the fingers, warm water, &c. A copper ball is then tried at gradually increasing temperatures. Up to 250° C. it repels both equally, above that the black is more repelled than the white, and at a full red heat the repulsion of the black disc is very energetic. A lighted candle acts with more energy than the red-hot copper.

The presence of even a small quantity of aqueous vapour in the exhausted apparatus almost, if not quite, neutralises the more energetic action which luminous rays appear to exert on a blackened surface.

After describing several different modifications and some new forms of apparatus devised to facilitate experiment, the author gives a drawing of an instrument which enables him to get quantitative measurements of the amount of incident light falling on it. It consists of a flat bar of pith, half black and half white, suspended horizontally in a bulb by means of a long silk fibre. A small magnet and reflecting mirror are fastened to the pith, and a controlling magnet is fastened outside so that it can slide up and down the tube, and thus increase or diminish sensitiveness. The whole is completely exhausted and then inclosed in a box lined with black velvet, with apertures for the rays of light to pass in and out. A ray of light reflected from the mirror to a graduated scale, shows the movements of the pith bar. The degrees of deflection produced by the light of a candle at distances from 6 feet to 35 feet are given.

The experimental observations and the numbers which are required by the theoretical diminution of light with the square of the distance, are sufficiently close, as the following figures show:—

Candle	6	feet off gives	a deflection of		218°
„	12	„		„	54
„	18	„		„	24·5
„	24	„		„	13
„	10	„		„	77
„	20	„		„	19
„	30	„		„	8·5

The effect of two candles side by side is practically double, and of three candles three times that of one candle.

The action of various solid and liquid screens is next given.

A candle three feet off, giving a deflection of 180°, has its action reduced to the following amounts by

Yellow glass	... ...	161°
Blue „	... ...	102
Green „	... ...	101
Red „	... ...	128
Water „	... ...	47
Alum „	... ...	27

A candle on each side of the apparatus, and equidistant from it, keeps the index ray of light at zero; by shading off either one or the other the light flies off to either extremity of the scale. This gives a ready means of balancing two sources of light one against the other. Thus,

[1] Paper read at the Royal Society, Feb. 10, by William Crookes, F.R.S., &c. Part III.

retaining the standard candle 48 inches off, on the left of the bar, the index is brought to zero by placing on the right

2 candles	67 in. off.
1 candle behind solution of sulphate of copper	6 „
„ „ alum plate	14 „
A small gas burner	113 „

These experiments show how conveniently and accurately this instrument can be used as a photometer. By balancing a standard candle on one side against any source of light on the other, the value of the latter in terms of a candle is readily shown; thus in the last experiment the standard candle 48 inches off is balanced by a gas-flame 113 inches off. The lights are therefore in the proportion of 48^2 to 113^2, or as 1 to $5\frac{1}{2}$. The gas-burner is therefore equal to $5\frac{1}{2}$ candles.

By interposing screens of water or plates of alum, and so cutting off the dark heat, the actual luminosity is measured. In addition to this, by interposing coloured glasses or solutions, any desired colours can be measured either against the total radiation from a candle, its luminous rays, or any desired colour. One coloured ray can be balanced against another coloured ray, by having differently coloured screens on either side.

The variations in the luminosity of a "standard" candle will cease to be of importance. Any candle may be taken; and if it be placed at such a distance from the apparatus that it will give a uniform deflection, say of 100 divisions, the standard can be reproduced at any subsequent time; and the burning of the candle may be tested during the photometric experiments by taking the deflection it causes from time to time, and altering its distance, if needed, to keep the deflection at 100 divisions.

If the pith bar in this instrument be blacked on alternate halves, an impetus given by a ray of light always acts in the same direction of movement. A candle causes it to spin round very rapidly until the suspending fibre is twisted up, and the rotation is stopped by the accumulated torsion.

By arranging the apparatus so that the black and white surfaces are suspended on a pivot instead of by a silk fibre, the interfering action of torsion is removed, and the instrument will rotate continuously under the influence of radiation. To this instrument the author has given the name of the "Radiometer." It consists of four arms of very fine glass, supported in the centre by a needle-point, and having at the extremities thin discs of pith lamp-blacked on one side, the black surfaces all facing the same way. The needle stands in a glass cup, and the arms and discs are delicately balanced so as to revolve with the slighest impetus.

In the "Proceedings of the Royal Society" last year, the author gave a brief account of some of the earlier experiments with these instruments. In the present paper he enters very fully into the various phenomena presented by them, and gives Tables showing the number of revolutions made by the radiometer when exposed to a constant source of light removed different distances from the instrument. The law is that the rapidity of revolution is inversely as the square of the difference between the light and the instrument.

When exposed to different numbers of candles at the same distance off, the number of revolutions in a given time are in proportion to the number of candles, two candles giving twice the rapidity of one candle, and three, three times, &c.

The position of the light in the horizontal plane of the instrument is of no consequence, provided the distance is not altered; thus two candles, one foot off, give the same number of revolutions per second, whether they are side by side or opposite to each other. From this it follows that if the radiometer is brought into a uniformly lighted space it will continue to revolve. This is proved to be the case by experiment.

The speed with which a sensitive radiometer will revolve in full sunshine is almost incredible. Nothing is visible but an undefined nebulous ring, which becomes at times almost invisible. The number of revolutions per second cannot be counted, but it must be several hundreds, for one candle will make it spin round forty times a second.

The action of dark heat (*i.e.*, from boiling water) is to repel each surface equally, and the movement of the radiometer is therefore arrested if a flask of boiling water is brought near it. The same effect is produced by ice.

From some observations made by the author, it appears probable that heat of a still lower refrangibility repels the white more than it does the black surface. Many instances are given of the radiometer revolving the reverse way. Thus, breathing gently on the instrument will generally cause this effect to be produced.

An experiment is described with a radiometer, the moving parts of which are of aluminium, blacked on one side. When exposed to the radiation from a candle, the arms revolve the normal way. On removing the candle they revolve the reverse way. Heated with a Bunsen burner the arms revolve the normal way as they are getting hot, but as soon as the source of heat is removed and cooling commences, rotation sets up in the reverse way, and continues with great energy till the whole is cold. It appears as if the reverse movement during the cooling is equal in energy to the normal movement as it is being heated.

It is easy to get rotation in a radiometer without having the surfaces of the discs differently coloured. An experiment is described with one having the pith discs blacked on both sides. On bringing a candle near it, and shading the light from one side, rapid rotation is produced, which is at once altered in direction by moving the shade to the other side.

The author describes many forms of radiometer, by means of which the movements can be exhibited to a large audience, or can be made to record themselves telegraphically on a self-recording instrument.

THE WATER SUPPLY OF THE METROPOLIS

IN the concluding portion of his anniversary address printed in the last number of NATURE (p. 376), the late president of the Geological Society severely criticises the proposal of the Rivers Commissioners to supply London with pure spring water. The Commissioners advise that the drinking water of London should continue to be derived from its present sources, but that it should be led away to its destination before it is mixed with the sewage of Oxford, Reading, Windsor, and other towns, and before it is fouled by the filthy discharges of paper mills and by other disgusting refuse.

Mr. John Evans thinks that it can hardly be believed that such a proposal as this should have been brought forward, involving, as he believes it would, if carried out, the conversion of the "fertile meadows" of the Thames Valley into "arid wastes," and the utter destruction of "watercress beds, now of fabulous value;" he adds that "even the canals and navigable rivers will become liable to sink and be lost in their beds." In predicting these dire results, he doubts whether his "judgment is *seriously* distorted," although he admits being deeply interested in the water power of one of the threatened valleys, and protests that no one can submit silently to an insidious (?) attack upon his property.

Having carefully studied for many years the hydrographical features of the Thames and other valleys, I have no hesitation in saying that Mr. Evans's fears are, for the most part, entirely unsupported by experience. Sterility

of surrounding land has not accompanied the withdrawal of vast volumes of water from the deep wells at Deptford, Thames Head, Caterham, Canterbury, Watford, Tring, or Lichfield, and it is singular that Mr. Evans should have overlooked the fact that moisture is supplied to growing plants from above and not from below. However numerous the wells of a given district may be, the rain must still fall upon the surface of, and soak through, the land before it can reach them.

As the *dry-weather* flow of the Thames even above Teddington lock is 600 millions of gallons daily, it would be waste of time to discuss seriously the possibility of canals and navigable rivers sinking into their beds in consequence of the abstraction of about one-eighth of that volume from springs and deep wells in that portion of the river basin. With regard to the water-cress interest, it is true that the Rivers Commissioners have not been so deeply impressed as Mr. Evans with the stupendous importance of this department of Thames agriculture, but it can scarcely be doubted that a wealthy city, containing 4,000,000 of inhabitants, would be able and willing to pay for any damage which it might inflict upon this or any other branch of industry.

The two most disgusting impurities revealed by the microscope in Thames water, as delivered for dietetic purposes in London, are the fibres of partially digested flesh meat, and those of variously coloured rags. The presence of these objects in our potable water clearly indicates the two chief kinds of *insoluble* polluting matter cast into the Thames, although chemical analysis cannot always trace to its sources the *dissolved* animal and vegetable impurities which it finds accompanying these insoluble materials. The question raised, therefore, is simple enough :—Shall the inhabitants of this "overgrown city," as Mr Evans contemptuously terms it, drink the pure spring water which nature offers them in singular abundance in the Thames valley, or shall they not be permitted to taste this sparkling beverage until the paper manufacturers, in the exercise of what they call their rights, have washed their filthy rags in it, and half a million of people have polluted it by their drainage?

It is remarkable that whilst Mr. Evans shows so much consideration, in his presidential address, for the pockets of the watercress-growers, he has so little to bestow upon the inhabitants of the overgrown city, for he does not hesitate to propose that the latter should encounter the expense of two separate water services—one (pure) for dietetic, and a second (polluted) for other domestic purposes. Now, leaving out of consideration altogether the risk of the polluted water being often used for dietetic purposes instead of the pure, and the enormous cost and inconvenience of laying and maintaining a new set of water-mains throughout the hundreds of miles of London streets; the supply of each house with a new water service, together with the necessary alterations of the old pipes, could not cost, on the average, less than 4*l*. In February last 523,801 houses were supplied with water by the eight metropolitan companies, and we have consequently here an expense of more than 2,000,000*l*. Surely a very small fraction of this sum would suffice to buy up any injured watercress-growers, even at "fabulous" prices.

In their sixth report, the Rivers Commissioners of 1868 state that the basin of the Thames, including that of its tributary, the Lea, is upwards of 5,000 square miles in extent. Rather more than one half of this area, including the oolitic and cretaceous formations, is covered by a porous soil upon a permeable water-bearing stratum, the remainder being occupied by the Oxford, Kimmeridge, gault, and London clays. The annual rainfall of this district averages about 28 inches, or 5,217 millions of gallons per day. Two-thirds of this vast volume of water is lost by evaporation, while, of the remaining one-third, one-half passes away in floods, and the other half only is at present available for springs and deep wells. But even this small fraction amounts to 870 millions of gallons daily, and it is proposed to take for the supply of the metropolis only 120 millions of gallons after it has practically performed all its fertilising functions; whilst, of this volume, there is even now supplied to London, in dry weather, about twenty-two millions of gallons. It is highly probable, however, that the volume of water available at present for springs and deep wells could be augmented to an extent commensurate, or nearly so, with the amount so abstracted for the supply of London. The chalk, and to some extent the oolite of the Thames basin, constitute an immense sponge which sops up the water falling upon it and maintains it, partly by capillary attraction and partly by its resistance to flow, at considerable elevations above the nearest rivers. This sponge has been aptly likened by Mr. Thornhill Harrison to an inverted reservoir, and just as the dry-weather flow of the Thames and its tributaries could be augmented by the judicious use of artificial storage reservoirs, so could the total yield of spring water from this vast natural reservoir be increased, by artificially bringing the water in it to a lower level before the occurrence of the autumn and winter floods. The spongy reservoir would thus be rendered capable of receiving those heavy rainfalls which, at present unable to find storage room below, either run off the saturated surface and constitute the winter floods, or immediately displace a corresponding volume of spring water from the sponge forcing it into the Thames and its affluents.

In the concluding paragraphs of his address Mr. Evans tries to show, from the results of chemical analysis, that the polluted water of the Thames is purer than the spring water from the chalk, and he thus seeks to make the inhabitants of the metropolis content with their present supply. His statements on this subject are founded upon an entire misconception of the meaning of the analytical results. A most exhaustive chemical examination of the river waters of the Thames basin, on the one hand, and of the spring and deep-well waters on the other, has shown, in the most unmistakable manner, the immense superiority of the latter for dietetic purposes. Indeed, it is obvious that, even with the most efficient river conservancy imaginable, aided by the best efforts of the Legislature, the Thames must always receive so much pollution as to render its use for the supply of the metropolis highly objectionable. No preventive measures can hinder the washings of highly-manured land, the excrements of cattle, the imperfectly purified sewage of towns and villages, and the partially cleansed discharges from paper-mills, skinneries, and tanyards, from mingling with the stream in enormous volumes. Such matters, though not obviously offensive to the senses (when this highest practical stage of purification has been reached), are still, from a sanitary point of view, of a very dangerous character. But even if this were not so, and if fatal results had never been known to follow the domestic use of such water, the refined feeling which separates the civilised man from the savage, and which excites loathing at the bare idea of organic matter, which has recently formed part of a human body, being supplied for human consumption, ought here to assert itself, and secure the rejection of such a beverage.

E. FRANKLAND

SCIENTIFIC NOTES TAKEN IN THE HIMALAYAS

I.—*Atmospheric Absorption.*

THE following notes refer chiefly to spectroscopic work, and they are, I think, of interest, as they show the importance of establishing a regular series of similar observations at different points of the globe.

Prof. Vogel has lately published in Poggendorff's *Annalen* the results of his observations taken in the Red Sea and in the Indian Ocean. He comes to the

conclusion that the relative intensity of the blue and red end of the solar spectrum is subject to great variations, variations which do not seem to stand in a simple relation to the hygroscopic state of the atmosphere or to barometric pressure. My results, while entirely confirmatory of those of Vogel, point to the fact that in the higher regions of the Himalayas, and at the season the observations were made, atmospheric absorption takes place chiefly in the red end of the spectrum. The blue end of the solar spectrum, even when the light of the sun has passed through a cloud, is remarkably bright.

The following extract from my note-book will place this fact beyond doubt. The observations were conducted at Simla with a spectroscope of eight prisms of about 60°. The direct sunlight was reflected by means of a small mirror into the slit. The slit was generally adjusted until one line between D_1 and D_2 was distinctly seen. As far as I could judge, all the lines, but not more than those given in Angström's map, were seen. The rainy season had just begun, but had not yet appeared in the violent way it did after my departure from Simla :—

Extract from Note-book.

June 27, 8 A.M.—B beautifully shaded. Light visible in the blue as far as wave-length 4040, and most likely further, but the telescope cannot be moved to greater deviation.

9 A.M.—Space beyond B closes up, while in the blue the spectrum is as visible as before.

Red end closes up. Blue perfectly visible.

11.15 A.M.—The red closed up still more. The blue as clear as before.

The sky is beautifully blue, but a slight halo seen round the sun.

July 3, 5.30 P.M.—The atmospheric lines near D seen distinctly. The blue is exceptionally clear and visible as far as H. Sky rather cloudy, and halo round the sun.

6.30 P.M.—Sun very near horizon. Spectrum seen from C to G.

In judging on the visibility of the spectrum, it should be borne in mind that, owing to the great number of prisms, a great part of the absorption in the blue was due to the glass, and that, therefore, owing to the great dispersion in the blue and instrumental absorption, the blue was seen under peculiar disadvantage. The above are only a few out of many observations. I have observed the passage of a cloud in front of the sun without any apparent effect in the blue, while the red end was all cut off.

I was at the same time struck by the fact that the peculiar redness of the clouds in the evening, which we observe so often in our climates, was only rarely seen, and when seen the colour was rather yellow than red. On making this remark to a friend competent to judge, and who through a repeated sojourn in Simla was enabled to form an opinion, I heard that the redness of the sky at sunset was often and beautifully seen at the end of, and after the rainy season.

I now pass to a few observations which I have made in Upper Thibet, a country which lies beyond the range of the rainy season. The observations all point to the remarkable clearness in the blue. As I have said, the hygroscopic state of atmosphere, as measured by the wet and dry bulb or barometric pressure, cannot alone account for all the phenomena. I find, for instance, that the presence of vegetation affects the atmospheric absorption in a remarkable degree. In the Kyan Chu plain, for instance, the plateau on which I observed the mirage described in NATURE (vol. xiii. p. 67), objects at ten miles distance look as sharp and distinct as those half a mile off. It is, in fact, impossible to judge of distance. Crossing the Tagalung Pass (18,000 feet), we descended from that plain into the valley of the Indus. As soon as we reached vegetation, at a distance of only two marches from the above-mentioned plain, and at height still above 12,000 feet, the whole aspect of the country is a different one. Distant mountains now take that lofty blue colour which gives such peculiar charm to the landscape. In the evenings especially you cannot help knowing that there is something between your eye and a distant object which affects its colour and distinctness, and through it you get a standard for judging distances. Without vegetation, even at a lower height, as, for instance, in the valley of the Bagha (Lahoul), you seem to look through a vacuum. In the upper part of the valley of the Indus, of which I am now speaking, I have not seen that clearness in the atmosphere which I have invariably seen in Switzerland at a height of 3,000 feet. The strong radiating power of the sun, which stands much more vertical in India, is evidently the cause of this, for it can only be organic matter floating in the atmosphere which can produce such a striking result. That the absence of any rain or deposit of any kind must not be left out of account is clear. The air in the side valleys of Cashmere, although rich in vegetation, is particularly transparent. Strange enough the principal valley of Cashmere, *i.e.* the valley of the Jehlum, is generally hazy, although there is a good deal of rain.

I have seen the planet Mars look almost white ; Jupiter and the other stars at that time had a bluish tint.

II.—*Glaciers.*

On the maps of Upper Thibet one finds a great many glaciers marked down. From my knowledge of glaciers I would not have given to these frozen masses of snow the name of glaciers. On inquiring further into the matter, I find that from measurements made by Schlagintweit these so-called glaciers have only very little, if any motion ; and judging from what I have seen and heard, I should say they must be only half-formed glaciers. The cause of this seems to me to be the want of pressure above the glaciers. In a country where the snow line is 19,000 feet high, and in which the mountains are seldom over 21,000 feet—for such is the country I am talking of—there cannot be a sufficient pressure to convert the snow into a clear mass of ice. I am however told that there is in Spiti one, but only one, glacier which deserves the name.

III.—*Temperature of the Blood.*

I am sorry that my observations on the temperature of the blood were cut short by untimely breakage of the thermometers. I have taken, however, a few observations in the plains of India, when the temperature of the air was higher than that of the blood. In a temperature of about 100° the blood was little above 98°.

IV.—*Parhelia.*

According to received opinions, parhelia are due to the refraction of light through crystals of ice. If this explanation is correct, and there seems to be no reason to doubt it, the following observations are of interest, as they show that even at the equator ice-clouds exist, and that parhelia are more often seen in India than in England. I have only once been lucky enough to see a parhelion in England, and that was since my return from India. In tropics and in the Himalayas I have seen within four months, eight times a rainbow-coloured ring round the sun. Its distance from the sun could only be measured by rough means, but it seemed to me to be larger than the generally given value of 22°, although near it. I subjoin the various observations :—

1. May 3.—Near Singapore, about sixty miles north of equator, at 5 o'clock P.M., part of a rainbow-coloured ring was seen, with the sun as centre. It stood on the white edge of a dark cloud.

2. Aug. 1.—At Dwara, in the Kulu Valley, almost the exact reproduction of the above phenomenon was seen on a cloud hanging on the side of a mountain. It was during the rainy season, at a height of about 5,000 feet. Weather rather hot.

3. Aug. 3.—Near the top of the Rotang Pass (13,000'), about 9 o'clock A.M., the lower half of a beautifully-coloured ring was seen for about half an hour.

4. Aug. 5.—Gondla (10,000'). At 3 P.M. a beautifully-coloured ring round the sun was seen on a very thin film of clouds in front of the sun. The blue was most distinct, and much purer than in the common rainbow.

5. Sept. 19.—While going down the Jehlum in a boat from Islamabad to Srinagur, I saw in the river the reflection of part of a coloured ring. Looking directly at the cloud, I saw the ring again on the white edge of a cloud. The sun was nearly setting.

6. Sept. 23.—At Baramula, at 4 P.M., I saw the same ring described above most distinctly, and making a complete circle round the sun.

7.—Marching out of Cashmere I was struck one morning by the appearance of the cloud being nearly the same as when I had before seen the circle in question. On looking carefully I could indeed see a faint trace of the ring.

8. Oct. 6.—At Peshawur (Punjab) I saw to the right of the setting sun about the sixth part of the coloured ring.

ARTHUR SCHUSTER

VISIT OF THE CHEMICAL SOCIETY TO THE ROYAL ARSENAL

IN response to an invitation from its president, Prof. Abel, F.R.S., the chemist of the War Department, nearly 500 Fellows of the Chemical Society visited the Royal Arsenal at Woolwich on Tuesday last. The presidents of most of the learned societies, together with other eminent men of science, were included in Mr. Abel's liberal invitation, so that during the day a constant stream of visitors flowed through the interesting workshops at Woolwich.

Beyond the ordinary attractions of the establishment, Mr. Abel had arranged to demonstrate the more important applications of science to warfare, and among these were included some experiments with gun-cotton and other explosives, the study of which he has made peculiarly his own. Indeed, the most attractive part of the programme from a scientific point of view was that carried out on the outskirts of the arsenal in the vicinity of the proof butts, where operations commenced by the firing of the big 80-ton gun. Col. Younghusband, F.R.S., R.A., the Superintendent of the Royal Gun Factories, as well as other heads of departments, had entered warmly into the spirit of the visit, and took considerable pains that every opportunity should be given the Fellows of witnessing the capabilities of this monster weapon. A charge of 250 lbs. of gunpowder, the grains of which measured nearly two inches cube, was introduced into the gun, and then the heavy bolt, or projectile, weighing 1,260 lbs. was rammed home. Those who were privileged to enter the chronoscope room, which is so small unfortunately, that scarcely a score of visitors could find room in it, were gratified with a sight of Boulanger's instrument for calculating the velocity of a cannon-ball in its flight, and as the thundering discharge was heard, this delicate apparatus proclaimed, simultaneously, that the projectile had been sent on its way at a velocity of nearly 1,500 feet a second, an impetus, it is said, sufficient to make a hole through the *Inflexible* ironclad, with her twenty inches of armour and thick teak backing. The Boulanger instrument is easily explained. Placed in front of the gun, at an interval apart, are two wire screens, so arranged that the projectile in its flight tears through them one after another. From two magnets attached to the instrument hang two metal rods, and the instant the first wire screen is torn by the shot, a current of electricity is broken and the first of these rods falls. As No. 1 is in the act of falling, however, the second wire screen is broken by the shot releasing No. 2 rod, and this sets in action a trigger which strikes No. 1 rod before it has yet completed its fall. If the shot has been slow in travelling from one screen to another, then rod No. 1 has, naturally enough, nearly fallen its entire length before it receives a stroke from the trigger; and the higher the mark is upon the rod No. 1, or in other words, the more it has fallen the less rapid has been the passage of the shot. After the mark is made one has merely to refer to a scale to get the velocity.

After the firing of the 80-ton gun came the gun-cotton programme, which Mr. Abel and Mr. E. O. Brown had arranged for the purpose of demonstrating in the first place the peculiar qualities of this explosive, and secondly its application to war purposes. To quote from this programme, Mr. Abel first gave "illustrations of some of the conditions which promote detonation of an explosive agent by a blow, or by the force exerted by an *initial* detonation." It was shown that gun-cotton refused to detonate except under very special circumstances, that is to say, neither a confined charge of gunpowder nor a small charge of unconfined mercuric fulminate brought about that result, which was only effected by a confined charge of fulminate, or by other masses of gun-cotton being detonated in its immediate vicinity.

Mr. Abel then went on to demonstrate the high speed at which detonation travels, the same being faster than any known agent, if we except electricity and light. A row of gun-cotton cakes half an inch apart, 36 feet long, was detonated at one end, and by crossing the row with several insulated wires connected with Noble's chronoscope (the wires being broken one after the other, as the detonation proceeded), it was proved that the velocity of the detonation exceeded 18,000 feet per second.

But it was the last of the gun-cotton experiments which proved the most interesting to the general body of visitors, as they illustrated the important uses of this valuable explosive. In these trials the gun-cotton was employed for the most part in a *wet*, and therefore *uninflammable* state, in which condition it detonates just as readily as when dry, provided a small charge of desiccated cotton is used to start the action. First of all, the value of detonation was shown in connection with cavalry raids in an enemy's country. Provided with a few pounds of gun-cotton and some fulminate fuses, a trooper might cut half-a-dozen lines of railway with very little ceremony, for, as Mr. Abel plainly showed, an eight ounce cake of the material exploded upon a rail, fractured the metals so completely as at once to block the line. In the demolition of wooden stockades, such as have caused us some difficulty in Perak lately, gun-cotton was shown to be equally efficacious, for a charge of wet cakes placed at the foot of such a structure on Tuesday last, levelled the same to the ground far more quickly than it takes to tell of the incident. Finally, a torpedo was fired under water constructed in the most primitive manner, by simply filling a large potato-net with gun-cotton slabs, and throwing it bodily into the water, a fuze and dry primer being contained in the middle of the charge.

After lunch, which the president had hospitably provided for his numerous guests, and at the close of which Dr. Hooker, C.B., P.R.S., took the opportunity of thanking Mr. Abel for the intellectual treat he had provided them with, the visitors had the satisfaction of witnessing the process of big gun making, a forging of fifty tons of glowing metal (the coil of one of the 80-ton guns) being worked under the monster 40-ton steam-hammer for their especial behoof.

The last sight of all was certainly not the least interesting. It was the run of a Whitehead torpedo under water, the machine, as our readers may know, being shaped in the form of a cigar and propelled through the water, rocket-fashion, by means of compressed air, which issues from its tail. The passage of this submarine monster the whole length of a canal, termed the torpedo

range, brought to the close a day which the fortunate Fellows of the Chemical Society will certainly remember as one of the most instructive and enjoyable in their varied experiences.

NOTES

It is with the greatest regret that we announce the death of Col. Strange, the Inspector of Instruments to the Indian Government, who died on the 9th instant. We shall give an obituary notice next week.

An impression has become general, through the statements of our contemporaries, that the Sub-Wealden boring has been permanently stopped. This is not the case; for at the last meeting of the committee it was determined to carry it on to a depth of 2,000 feet, and if funds continue to flow in with the success which has previously characterised this movement, the boring, it is hoped, will be carried to the greatest depth attainable. The boring has now reached a depth of more than 1,900 feet, and was to be recommenced this week; should, however, a greater depth than 2,000 feet be determined on, it will be necessary to enlarge and reline the hole, which will cost from 600*l.* to 700*l.* Arrangements are being made by which it is hoped that a continuous core may be obtained from the present depth to that of 2,000 feet. We believe the Government grant of a pound a foot for each foot bored ceases at 2,000 feet, and, looking to the important light the prosecution of this boring will throw, not only on many theoretical questions of modern science, but on so many doubtful points of practical interest to England, it is sincerely to be hoped that the advisability of continuing the grant will be seriously considered by her Majesty's Ministers.

We have received from Messrs. Allsopp and from Dr. Hassall letters referring to the statement noticed in our review of the work of the latter on Food (vol. xiii. p. 345), that the water used by the former in the brewing of their ales contains 7·65 grains of sulphate of zinc. Dr. Hassall expresses great annoyance that through some inadvertence on his part this unfortunate error, as it obviously is, should have been allowed to get into his book. He points out, what no doubt would be evident to most readers, that sulphate of *zinc* is a mistake for sulphate of *potash*. He assures us that no trace of so deleterious a substance as sulphate of zinc has been found in the water used by Messrs. Allsopp, and that their celebrated bitter beer consists solely of the products of malt and hops, and the constituents of pure spring-water. A further letter from Dr. Hassall, for which we have not space, will be found in our advertisement columns.

We are informed that Mr. J. E. Harting is engaged in editing for the "Transactions of the Norfolk and Norwich Naturalists' Society" ten unpublished letters of Gilbert White, which have recently come to light. The originals are in the possession of the Rev. H. P. Marsham, of Rippon Hall, near Norwich, and are addressed to his great grandfather, Mr. Robert Marsham, F.R.S., of Stratton Strawless, Norfolk. It is expected that this interesting publication will appear about the end of this month or early in April.

Mr. Stanford has sent us specimens of some very fine maps recently published by him. Two of these are Orographical maps of Europe and of England, and the public in general and educationists in particular ought to be grateful to Mr. Stanford for thus putting within their reach a style of map which has hitherto been peculiar to Germany. The maps are really admirable specimens of a very difficult kind of cartography, and we have only one fault to find with them. Unfortunately, the midland levels are coloured green, while the sea is coloured blue, so that by gaslight the boundary cannot be distinguished. Why not have the nearest approximation to sea-level coloured white, the various higher levels of the land graduated shades of brown, and those of the sea by various shades of blue or green? This would be a simple and, we think, most intelligible plan. If the slight defect we mention—and it is only noticed under artificial light—were remedied, the maps would be nearly all that could be desired. The third map is a large-scale one, in four sheets, of British Guiana. The map is compiled from the surveys executed under H.M.'s Commission for 1841-44, and under the direction of the Geographical Society, for 1835-39, by Sir R. H. Schomburgk, revised and corrected to the present time by Mr. Cathcart Chalmers, Crown Surveyor of the Colony, and Mr. J. Gay Sawkins, Director of the Geological Survey of the West Indies and British Guiana, with additions by Mr. C. B. Brown. It will thus be seen that the map has been constructed on the latest and most trustworthy authorities. It is a curious fact that the boundaries between British Guiana and Venezuela on the one hand and Brazil on the other have never been properly adjusted.

We have received a very important letter by Mr. Russell Government Astronomer at Sydney, which we regret that we have not space to reproduce *in extenso*. The letter refers to the excessively dry weather of Australia, which, indeed, has been so dry as to be really alarming, and reviews the results of rainfall observations made at Sydney during the last thirty-six years. This letter suggests to us that the unusual wet weather we have had here may be more than compensated by the excessively dry weather which has prevailed in Australia.

The Duke of Richmond and Gordon stated in the House of Lords no Tuesday that the Vivisection question was under the consideration of the Government, but he could not say when any legislation would take place upon it.

A few days ago a meeting was held in Birmingham for the purpose of establishing a Philosophical Society, and it was found that the proposal met with very warm support. Some difference of opinion was expressed as to the propriety of including literary subjects in its programme, but the general feeling was in favour of keeping to a purely scientific course. A society of this kind is greatly wanted in this important centre, for science is represented there only by the Natural History Society, which, though it has done some good work, is found to have too limited a scope. With the prospect held out by the munificent founder of Mason's College for advanced scientific culture, there can be little doubt that such a society would do great good, and we wish it every success. A proposal for amalgamating the Natural History Society with the new Society has been made, and has been favourably entertained.

Mr. R. W. Cheadle is announced as having been successful in excavating from the well-known brick earth pit at Crayford a bone which was identified by Prof. Morris as the thigh-bone of a British species of lion. Mr. Cheadle found at the same time several rhinoceros' teeth in this cemetery of ancient life among the hop gardens of Kent.

Petermann's *Mittheilungen* for March contains several important papers. H. Habenicht contributes a brief description to accompany a carefully, and notwithstanding its size, remarkably clear map of Europe, showing the distribution of the sedimentary rocks on that continent. A map of South New Guinea between 142° and 143° E. long. shows the course of the recently discovered Baxter River, accompanying which are accounts of the Macleay expedition and of Macfarlane and Stone's exploration of the Baxter River or Mai-Kassa. Lieut. Weyprecht continues his "Sketches from the Far North," in this part treating of the ice-pressure. The account of Lieut.-Col. Przewalsky's

travels in Mongolia and the Land of the Tunguts is continued also.

AT Monday's meeting of the Royal Geographical Society, the principal business was the reading of papers on the interior of New Guinea, by Mr. Stone and Mr. Macfarlane. The writers had found the coast district of New Guinea too barren "even for the cultivation of the banana," but concurred in stating that the country improved considerably as they travelled inland. There they found great fertility, a kind, hospitable people, and a country comparatively free from fever, whereas the coast was barren, the people were morose and warlike, and the climate was destructive of the health of Europeans.—No communication was made respecting Lieut. Cameron, but it was understood that at the last advices he was with his party at Loanda.

THE general staff of the German empire has published a report of experiments made in Germany on ballooning at the expense of the Imperial Government. The conclusions throw no new light on the subject, but the German officers believe that the mechanical direction of balloons is by no means an impossibility. They even suppose that the problem of ascending or descending without using ballast or the valve, is very likely to receive a speedy solution. They propose to the Government to determine by means of experiments what is the best diameter for the helix when it is applied to a balloon of a certain capacity. They propose also to try the efficacy of wings for propelling balloons. They are not of the common opinion that the diameter of balloons can be indefinitely enlarged.

MISS SHEEPSHANKS has presented to the Royal Astronomical Society 200 volumes of works on Astronomy, some of them very rare; and Lord Lindsay has presented a large and valuable collection of the late Mr. Carrington's MSS. on the subject of sun-spots.

AT the last regular meeting of the Berlin Geographical Society, Herr Kiefert read a paper on the African Expedition of Lieut. Cameron, which he described as epoch-making, and declared that the general results were the most important since Livingstone.

THE Museum of Paris has lost the services of two of its most eminent professors, M. Milne-Edwards in zoology, and M. Delafosse in mineralogy; they have been placed on the retired list on account of old age. M. Milne-Edwards has been succeeded by his own son, a promising naturalist, and M. Delafosse, by M. Decloizeaux, a member of the Institute.

ON the 4th inst. the Berlin University held an extraordinary meeting to celebrate the fiftieth anniversary of the day on which Prof. Dove was received a doctor. An address was handed to him by Professors Mommsen and Du Bois-Reymond. The Minister of Public Instruction was present, and a magnificent vase was presented to Dr. Dove on behalf of the Emperor of Germany. In the evening a banquet took place at the English Hotel. Among those present were Prof. Helmholtz and a number of other German scientific notabilities.

THE Société Française de Navigation Aérienne has awarded a gold medal and diploma "for devotion to science," to Mr. F. W. Brearey, honorary secretary to the Aeronautical Society of Great Britain.

THE change of Ministry has been completed in France, and M. Wallon is no longer the Minister of Public Instruction. The learned gentleman left behind many warm sympathisers. His successor appointed last Friday is Mr. Waddington, an Englishman by parentage, born in France in 1828, naturalised a Frenchman, and a member of the Senate, but a Protestant by religion, and educated at Rugby and Cambridge. Great efforts are likely to be made to secure for France competent representation at the forthcoming Scientific Loan Exhibition.

THE Cambridge Museums and Lecture-rooms Syndicate report the urgent necessity for increased accommodation in the departments of zoology, comparative anatomy, and physiology, and recommend that steps be at once taken to supply the want. They suggest the erection of a building on a site adjacent to the present museums, to consist of three floors, with cellars under the central portion.

M. HARENT, the director of a private institution, is now the President of the Municipal Council of Paris. He has deposited a formal proposition asking the Council to establish several meteorological observatories for the analysis of rain, water, air, electrical determinations, and ordinary barometer and temperature readings. All these establishments are to be modelled after that of Montsouris, but on a smaller scale.

THE Daily *Bulletin* of Weather Reports for March 1873 issued by the chief signal officer of the War Department of the United States, has been received. The publication gives on a reduced scale the whole of the tri-daily weather maps for the month, each map being accompanied with (1) the synopsis of the weather conditions, and (2) probabilities of the weather during the next twenty-four hours, drawn from these conditions, and stated on each map at the time of its publication, together with (3) a statement of the actual facts as they occurred with which the "forecasts" of the office may be compared. This fearless and straightforward course of exhibiting equally its successes and its failures, is deliberately adopted by the office in order to facilitate inquiry by scientific men, into the theories and causes which have led to these successes and failures, from which inquiries the practical work of the office cannot fail to reap most substantial benefit.

THE additions to the Zoological Society's Gardens during the past week include 171 Sand Lizards (*Lacerta agilis*) from Italy, presented by Mr. H. Negretti; two Forster's Milvagos (*Milvago australis*) from the Falkland Isles, presented by Lord Lilford; a Great Frigate Bird (*Frigata aquila*) from America, three Black-backed Geese (*Sarcidiornis melanota*) from India, a Gull-billed Tern (*Sterna anglica*), European, a Crested Hangnest (*Ostinops cristatus*), a Cayenne Lapwing (*Vanellus cayennensis*) from South America, an Ogilby's Rat Kangaroo (*Hypsiprymnus ogilbyi*), a Vulpine Phalanger (*Phalangista vulpina*) from Australia, purchased; a Jackal Buzzard (*Buteo jacal*) from Africa, deposited; a Yellow-footed Rock Kangaroo (*Petrogale xanthopus*).

SOCIETIES AND ACADEMIES

LONDON

Royal Society, Feb. 3.—On Formulæ of Verification in the Partition of Numbers, by J. W. L. Glaisher, M.A., F.R.S.

Feb. 17.—"Researches upon the Specific Volumes of Liquids." By T. E. Thorpe, Ph.D., F.R.S.E., Professor of Chemistry in the Yorkshire College of Science, Leeds.

II. *On the Specific Volumes of certain similarly-constituted Inorganic Chlorides.*

The results of the observations made by Pierre and Kopp upon the boiling-points, specific gravities, and thermal expansibilities of the trichlorides and tribromides of phosphorus, arsenic, and antimony, have led Kopp to suppose that the specific volumes of phosphorus, arsenic, and antimony, in their liquid combinations, may be identical. The same conclusion has been drawn with respect to tin, titanium, and silicon from Pierre's observations upon the tetrachlorides of these elements.

The common value of P, As, and Sb would appear to be about 27, that of Si, Ti, and Sn about 35. But on examining the details of the observations, it becomes evident that this conclusion is not strictly borne out by the results; the numbers obtained for the individual members of the group differ in many cases considerably from the common value, the divergences being far wider than could arise from errors of observation, either in the determination of the physical constants or in the estimation

of the atomic weights of the constituent bodies. In fact the order of the divergences would seem to render it probable that the specific volumes of the several members of a family of elements increase with their atomic weights.

In a former communication to the Royal Society the author has given the results of a series of observations on the specific gravities, boiling points, and rate of expansion of certain liquid chlorides of phosphorus. Since Roscoe has shown that vanadium is a member of the phosphorus group of elements, it appeared to him that a comparison of the specific volumes of the analogously constituted phosphoryl and vanadyl trichlorides might serve to throw additional light on this question of the relation of the specific volumes of the members of a family of elements to their atomic weights.

Three determinations of specific gravity of phosphoryl trichloride made with different bottles gave a mean number of 1·71185 at 0° compared with water at same temperature; compared with water at 4° the specific gravity is 1·71163.

The rate of expansion of phosphoryl trichloride from 0° to its boiling-point may be accurately represented by the expression—

$$V = 1 + 0{\cdot}001\,064\,309t + 0{\cdot}000\,001\,126\,66t^2 + 0{\cdot}000\,000\,005\,299t^3.$$

Its specific gravity at 107·23 is 1·50987; hence its specific volume $= \frac{153{\cdot}38}{1{\cdot}50987} = 101{\cdot}58$.

The results obtained with the dilatometer in the case of vanadyl trichloride may be represented by the formula

$$V = 1 + 0{\cdot}000\,965\,236t + 0{\cdot}000\,000\,898\,26t^2 + 0{\cdot}000\,000\,003\,191\,63t^3.$$

The mean of three experiments gives the specific gravity of vanadyl trichloride at 0°, compared with water at 4°, as 1·86527.

The specific gravity of vanadyl trichloride at 127°·19 is 1·63067; hence its specific volume is $\frac{173{\cdot}73}{1{\cdot}63067} = 106{\cdot}54$.

It is thus evident that the specific volumes of vanadyl and phosphoryl trichlorides are not equal; the compound with the higher molecular weight has the greater specific volume.

In the communication on the chlorides of phosphorus already referred to, it is shown that if it be assumed, as appears in the highest degree probable, that there is a relation between the manner in which the oxygen atoms in a compound are held in union and their specific volume, it follows that the oxygen atom in $POCl_3$ possesses the smaller of the two values 12·2 and 7·8 assigned by Kopp to oxygen, and accordingly that this atom is attached to the phosphorus by only one combining unit.

Thus—

```
Cl
|
P—O—Cl
|
Cl,
```

showing that the phosphorus atom in phosphoryl trichloride possesses the same atomic value as in phosphorus trichloride.

As the difference between the two values for the volume of oxygen, viz., 12·2 − 7·8 = 4·4, is but little less than between the specific volumes of $VOCl_3$ and $POCl_3$, viz., 106·54 − 101·58 = 4·96, it is possible that the difference in the specific volumes of the two liquids may be due to the different manner in which the oxygen atoms are united to the vanadium and phosphorus atoms; for, if V be regarded as a pentad, $VOCl_3$ must be written—

```
    Cl
    |
Cl—V=O
    |
    Cl,
```

the oxygen atom having the value 12·2. Assuming Kopp's value for Cl, viz. 22·8, this would leave for P and V nearly the same specific volume, viz.:—

P	25·4
V	25·9

From the uncertainty respecting the particular volume to be assigned to the oxygen atom in vanadyl trichloride, our knowledge of the specific volumes of $VOCl_3$ and $POCl_3$ gives us little aid towards solving the question whether the several members of a family of elements have identical specific volumes.

With a view to obtain further evidence, the author has redetermined with special care the boiling-points, specific gravities, and rates of expansion of the tetrachlorides of silicon, titanium, and tin.

The atomic weights of Si and Ti and of P and V show about the same gradational difference:—

Si	28·10	P	31·00
Ti	50·00	V	51·35

And, since the tetrachlorides are free from oxygen, the uncertainty arising from the specific volume of that element is eliminated. He has also compared the specific volumes of the trichlorides of phosphorus, arsenic, and antimony, making use of Kopp's determination in the case of the last-named compound. Material is thus obtained for the discussion of the question from analogous derivatives of two well-defined groups of elements, viz.:—

Si	28·10	P	31·00
Ti	50·00	V	51·35
		As	55·15
Sn	118·10	Sn	122·30

The results of the determinations of the specific volumes of the tetrachloride of silicon, titanium, and tin, liquids of analogous constitution and all derivatives of the tetrad group of elements, serve to establish the conclusion indicated by the difference in the specific volumes of phosphoryl and vanadyl trichlorides, that the specific volumes of the several members of a family of elements are not identical, but that the specific volume increases with the atomic weight of the member.

	Molecular weight.		Specific volume.
$SiCl_4$	169·94	...	121·13
$TiCl_4$	191·84	...	126·03
$SnCl_4$	259·94	...	131·41

It is also noteworthy that the difference between the specific volumes of tin and titanium tetrachlorides is almost the same as the difference between the specific volumes of vanadyl and phosphoryl trichlorides; the difference between the atomic weights of vanadium and phosphorus is nearly the same as that between the atomic weights of titanium and silicon.

	Mol. weight.	Diff.	Spec. vol.	Diff.
$POCl_3$ ...	153·38 ...	20·35	101·58 ...	4·96
$VOCl_3$ ...	173·73 ...		106·54 ...	
$SiCl_4$ ...	169·94 ...	21·9	121·13 ...	4·90
$TiCl_4$ ...	191·84 ...		126·03 ...	

It would seem from this that the constitution of vanadyl trichloride is similar to that of the phosphoryl compound, and must therefore be expressed by the formula—

```
Cl
|
V—O—Cl
|
Cl
```

in which V appears as a triad, the oxygen atom having the same specific volume as in phosphoryl trichloride. On the other hand, the order of the divergences shown by P, As, and Sb (*vide infra*), would appear to indicate that V may be pentad in this compound, whence O would have the volume 12·2.

The numbers representing the specific volumes of the trichlorides of phosphorus, arsenic, and antimony exhibit a gradational order similar to that shown by the volumes of the tetrachlorides of silicon, titanium, and tin, and also by the specific volumes of phosphoryl and vanadyl trichlorides:—

	Mol. weight.	Spec. vol.
PCl_3	137·38	93·54
$AsCl_3$	181·53	94·64
$SbCl_3$	228·68	97·82

although the differences are much less than in the cases of the two latter groups.

III. *On the Specific Volumes of Bromine and Iodine Monochloride; and of Ethene Bromide and Ethene Chloriodide.*

The molecular weight of bromine is, as is well known, nearly equal to the arithmetic mean of the molecular weights of chlorine and iodine: Hence the molecular weights of bromine and of iodine monochloride (ICl) are nearly identical. These substances closely resemble each other in physical properties. Both are dark-red liquids about three times heavier than water. Bromine boils at about 59°·5, and solidifies at −24°·5; iodine monochloride melts at +24°·5, and boils at 101°: the interval between the boiling- and melting-points is therefore approximately equal.

It appeared to the author of interest to determine (1) if the specific volumes of these liquids exhibit a relation similar to that which is shown by their molecular weights; and (2) if the relation in their specific volumes is preserved in analogous combinations of the two bodies. He has accordingly determined the specific gravities, boiling-points, and rates of expansion of bromine and iodine monochloride, and of the compounds which these substances form by their union with ethene, C_2H_4. The observations also serve to determine if bromine and iodine monochloride preserve, when in combination, the volumes which they possess in the free state.

It is evident from the observations that the specific volumes of bromine and iodine chloride are not equal, neither are the specific volumes of ethene bromide and ethene chloriodide; the bodies with the greater molecular weights have the greater specific volumes.

	Molecular weight.	Specific volume.
Bromine	159·90	53·62
Iodine chloride	162·31	56·32
Ethene bromide	187·90	97·30
Ethene chloriodide... ...	190·31	101·27

The number obtained for iodine monochloride differs considerably from the volume calculated by means of Kopp's values (Cl = 22·8, I = 37·5), viz., 60·3. The specific volume of bromine (Br_2) is also less than Kopp's number, 55·6. The value assigned to chlorine is unquestionably far more accurate than that given to iodine, since the value of the latter element was calculated from only two or three compounds, whereas the former number was deduced from a comparatively large number of chlorinated products. That the value for iodine needs revision seems to be confirmed by Billet's observations of the specific gravities of liquid iodine at various temperatures. If his results be plotted down and the curve prolonged to the boiling-point of iodine, we find that the specific gravity of iodine at this point is 3·780; hence the specific volume of iodine (I.)—

$$= \frac{126·85}{3·780} = 33·5.$$

If now this value be added to that of chlorine as given by Kopp, we get a result identical with the observed volume of iodine monochloride—

$$33·5 + 22·8 = 56·3.$$

If we subtract the specific volumes of C_2H_4, as calculated by the aid of Kopp's values ($C = 11$, $H = 5·5$, $C_2H_4 = 44$), from the specific volumes of ethene bromide and ethene chloriodide, we obtain numbers which are nearly equal to the specific volumes of bromine and iodine chloride respectively—

$$97·30 - 44 = 53·30.$$
$$101·27 - 44 = 57·27.$$

This correspondence between the two sets of values seems to warrant the conclusion that bromine and iodine chloride possess the same volume in a compound which they have when in the free state.

It is not unreasonable to suppose that the same may be true of ethene itself, viz., that at its boiling-point it would possess the same volume which it has in the bromide and chloriodide at their respective boiling-points. On this assumption the specific gravity of liquid ethene would be—

Calculated from $C_2H_4Br_2$	0·641
,, ,, C_2H_4ICl	0·624

Chemical Society, March 2.—Prof. Abel, F.R.S., president, in the chair.—This meeting was entirely occupied with the discussion of the various points in connection with water analyses, raised by Dr. Frankland's lecture at the previous meeting. The debate, which lasted until a late hour, turned chiefly on the respective merits of Frankland and Armstrong's "combustion method," and of the "albumenoid ammonia process" of Wanklyn, Chapman, and Smith, for determining the amount of impurity in potable waters.

Mathematical Society, March 9.—Wm. Spottiswoode, F.R.S., vice-president, in the chair.—Messrs. Cockshott and R. T. Wright were elected members, and Messrs. Elliott, Leudesdorf, and Russell admitted into the Society.—Prof. Cayley made communications on the bicursal sextic and on the problem of three-bar motion. The discovery by Mr. Samuel Roberts of the triple generation of a three-bar curve throws a new light on the whole theory, and is a copious source of further developments. Prof. Cayley gives in its most simple form the theorem of the triple generation; he also establishes the relation between the nodes and the foci, and further gives other researches. The two papers are intimately related to one another.—Prof. Clifford spoke on the classification of geometric algebras. He sketched out what had been done by Argand (1806); Möbius (1827); Peacock and the Cambridge School (1834); Hamilton (1843); Grässmann (1844, 1862); Peirce (1870); and mentioned results he has himself obtained, for some of which he had not yet got satisfactory explanations.

Zoological Society, March 7.—Dr. A. Günther, F.R.S., vice-president, in the chair.—Dr. Günther exhibited and made remarks on specimens of a minute Australian mammal (*Antechinus minutissimus*) and of a species of *Palythoa* parasitic on a Mediterranean sponge.—Prof. Garrod read a paper on the anatomy of the Courlan (*Aramus scolopaceus*), which he regarded as showing in many respects a close affinity to the Cranes (*Grus*).—A communication was read from Mr. T. E. Buckley, containing remarks on the past and present geographical distribution of the larger mammals of South Africa.—Dr. Cobbold, F.R.S., read the fourth of his series of notes on Entozoa.—Sir Victor Brooke, Bart., read some supplementary remarks on the newly discovered Persian Deer (*Cervus mesopotamicus*), based on additional specimens and information received from Mr. Robertson, H.B.M. Vice-Consul at Busreh.—A second communication from Sir Victor Brooke contained further observations on Schomburgk's Deer (*Cervus schomburgki*) of Siam.

Royal Microscopical Society, March 1.—Mr. H. C. Sorby, F.R.S., president, in the chair.—A paper was read by Mr. W. Hartley, F.C.S., descriptive of certain observations and experiments on the fluids contained in quartz cavities, and which appeared to be liquid carbonic acid, mixed in most cases with water. The subject was illustrated by drawings and by specimens, and experimental demonstrations under the microscope.—A paper was also read by Mr. F. Rutley on the structure of certain rocks, Obsidian and Leucite, and on the spheroidal structure observed in the perlites. The subject was freely illustrated by diagrams and specimens exhibited in the room. A paper by the Rev. W. H. Dallinger, on a new arrangement for illuminating and centering for high powers, was taken as read, it being understood that though of great interest it could not readily be explained without the numerous illustrations by which it was accompanied.

Institution of Civil Engineers, Feb. 22.—Mr. G. R. Stephenson, president, in the chair. The paper read was on the Probable Errors of Levelling, with Rules for the Treatment of Accumulated Errors," by Mr. Wilfred Airy, B.A.

Feb. 29.—Mr. Geo. Robt. Stephenson, president, in the chair. —The first paper read was on the floods in England and Wales during 1875, and on water economy, by Mr. George James Symons, secretary to the Meteorological Society.—The second paper read was on evaporation and on percolation, by Mr. Charles Greaves.

Victoria (Philosophical) Institute, March 6.—A paper on the Horus myth in its relation to Christianity, was read by Mr. W. R. Cooper, F.R.A.S.

MANCHESTER

Literary and Philosophical Society, Dec. 6, 1875.—Mr. C. Bailey, vice-president, in the chair.—Mr. Sidebotham, F.R.A.S., sent for exhibition some sand from a river far inland of New Guinea, containing particles of gold, magnetic and non-magnetic iron, foraminiferæ, silicified fragments of echini, and shells.—Mr. J. Cosmo Melvill exhibited two specimens of the Spurge Hawk Moth (*Deilephila euphorbiæ*), said to have been captured in the larval state at Ecclesbourne, near Hastings, feeding in all probability on *Euphorbia amygdaloides*, as he subsequently visited the spot and could see no trace of any other Spurge.

Jan. 17.—Mr. John Barrow in the chair.—Mr. Sidebotham, F.R.A.S., exhibited a magnified drawing and specimens of *Lymexylon navale* from Dunham Park, and read a short paper on the life history of the insect, which he and Mr. Chappell had studied since its discovery in Dunham Park in 1872. Mr. Sidebotham also read a paper on *Psammodius sulcicollis*, and exhibited specimens taken at Southport in 1875.—Mr. Plant exhibited various objects of interest, including a Longicorn Beetle (*Astinomus ædilis*) from a coal mine near Manchester; also cases of a North American Caddis Worm (*Phryganea* sp.) much resembling a mollusc of the genus Valvata, and once named by Lea *Valvata arenicola*.

GENEVA

Physical and Natural History Society, Jan. 20.—Dr. Prevost, Head Physician to the Geneva Cantonal Hospital, presented a photograph of the brain of a person who had been affected with aphasia. The lesion, which consists in a slightly yellowish softening somewhat like cicatrisation, occupies a space of about two centimètres on the posterior part of the third left frontal convolution. The meninges are adherent on a level with the diseased point. The "island" of Reil is healthy except at a point which touches the affected convolution. The interval separating two convolutions of the "island" presents a yellowish coloration, and contains granulous bodies. The convolutions themselves of the "island" are, on the other hand, sound. This brain belonged to a woman aged seventy-five years, affected for about a month with right hemiplegia without contractions and without loss of sensibility, and who presented an almost

complete aphasia. Incapable of speaking, she pronounced only isolated syllables without any meaning, as *Eh, eh :* Ah, oi ; - - - eh, *baba* - ah ! *ba, ba, za-za-ya*. One day she said *maman ;* this was the only comprehensible word she uttered. She succumbed twelve days after entry, to bronchitis, for which she came to the hospital. The lesion observed in this case is that which M. Broca regards as constant in cases of aphasia. It is known that M. Meynert and others, on the contrary, localise the faculty of speech in the lobule of the insula, which in the above case was scarcely touched. Dr. Prevost observed at the Cantonal Hospital another case of aphasia, in which the lobule of the insula was the seat of the lesion, while the third left frontal convolution was intact, and thinks we cannot localise exactly the faculty of language exclusively in either of the seats in question.

PARIS

Academy of Sciences, March 6.—Vice-Admiral Paris in the chair. The following papers were read :—Note on geodesic operations undertaken in Brazil, by General Morin. A Commission is to determine the position of a series of stations from Rio de Janeiro to the town of San Juan de Rio Claro, and the mouth of the Tiele in the Parana. There will be measured an arc of parallel of about 23° S. lat. and 9° to 10° in longitude; and an arc of meridian from about 2° N. lat. to about 33½° S. lat. or more than 35½°.—Transformation of nautical astronomy through the progress of chronometry, by M. Yvon Villarceau.—Note on the steam jacketing of engine-cylinders, by M. Resal.—On the periodical variations or inequalities of temperature, by M. Sainte Claire-Deville. From further data he is able to show that the oscillation of the half of Nov. 1873 was perceptible over Europe, Asia, and America and the northern part of Africa ; that is, over nearly the whole northern hemisphere. A similar oscillation in November, 1874, seems to be established.—On a new simplification of the fundamental law of electrodynamics, by M. Clausius.—The Academy nominated candidates for the vacant chairs of zoology and mineralogy ; MM. Alph. Milne-Edwards and Oustalet, for the former, MM. Descloizeaux and Janettaz for the latter.—On the absorption of bicarbonates by plants in natural waters, by M. Barthélémy. *Inter alia*, these bicarbonates do not serve the respiratory action, for the quantity absorbed is not in proportion to the rapidity of vegetation. During night, and in water equally saturated, the plants seem to excrete a part of the bicarbonates absorbed by day.—M. Dupuy de Lôme presented a memoir, by M. Bertin, on the rolling of ships.—M. Andrade described a new governor for steam-engines.—M. de Rostaing spoke of the antiseptic properties of the root of madder. A piece of meat had been kept from July, 1875, to February 1876, in a pot containing the root in powder form, and which had frequently been opened. The weight was reduced from 119 to 25 grammes. There was no odour nor development of live organisms.—Methods of transformation based on conservation of an invariable relation between derivatives of the same order, by M. Haton de la Goupillière.—Geometrical demonstration of a relation due to M. Laguerre, by M. Mannheim.—On the photometry of stars, and the transparence of the air, by M. Trepied. The author tabulates the intensities calculated for various stars.—Analysis of the white smoke of a blast furnace in the neighbourhood of Longwy, by M. Gruner.—Action of electrolytic oxygen on glycerine, by M. Renard. The glycerine diluted with two-thirds of its volume of acidulated water, is submitted to the electrodes from six Bunsen elements ; after forty-eight hours the liquor is saturated with carbonate of lime, filtered, and distilled, giving a dilute solution of glyceric aldehyde. The white residue, after evaporation, has for formula $C_3H_6O_3$; M. Renard describes its properties.—Note on the calorific action of certain regions of the brain (vaso-motor apparatuses situated on the hemispheric surface), by MM. Eulenberg and Lander. These experiments were on young dogs, which were submitted to chloroform and curare, and the brain-surface burnt with hot copper wire and stimulated with induction currents. As thermo-electric elements, Dutrochet needles were inserted under the skin of the paws, and were connected with a very delicate galvanometer. The authors define the efficacious calorific region, and the relation of its parts, and they explain the results by vaso-motor apparatuses there which are probably connected with vaso-motor fibres in the peduncle of the brain.—On the action of biliary salts on the pulse, the tension, the respiration, and the temperature, by MM. Feltz and Ritter. It is shown that by injections of natural bile into the blood, in proportions that are not toxical, the pulse is diminished in frequency, the respiration is retarded, and the temperature and arterial tension are lowered.—Some remarks on MM. Feltz and Ritter's note, by M. Bouillaud.—On the *rôle* of the arterial bulb in fishes, by M. Carlet. *En resumé* (1) the bulb preserves the branchial arterioles from the shocks communicated by the heart ; (2) it facilitates the action of the heart ; (3) if its action be prevented, there immediately follows a considerable disorder of the hæmatosis.—Note on inverted sugar, by M. Maumené.

FRENCH AND SWISS TROGLODYTES

Reliquiæ Aquitanicæ; being Contributions to the Archæology and Palæontology of Perigord. By Edouard Lartet and Henry Christy. Edited by T. Rupert Jones, F.R.S. (London: Williams and Norgate, 1875.)

Excavations at the Kesslerloch near Thayngen, Switzerland. By Conrad Merk. Translated by John E. Lee, F.S.A., F.G.S. (London: Longmans, Green, and Co., 1876.)

ALTHOUGH the term Aquitaine employed in the title of this work is used in its widest sense as embracing the whole country between the Loire and the Cévennes, the prehistoric researches recorded in the seventeen quarto numbers of it, which have appeared periodically, commencing in December 1865, are confined to the Province of Perigord, and chiefly to the valley of the Vezère, a tributary of the Dordogne.

Here the river, which has cut its way deeply into the cretaceous rocks of the district, has formed a narrow tortuous valley, bounded on either side at intervals by cliffs rising to a height of 300 feet in some places. Above this the surrounding country forms an extensive plateau, varying in altitude, but rarely rising to any great height above the summit of the valley.

Owing to the different degrees of hardness of the calcareous rocks which form the precipitous sides of the valley, the weathering of the face of the cliff has been very unequal, the softer portions yielding to the action of the atmosphere have formed deep grooves, and in places, caves as much as 30 feet in depth have been formed, extending some of them, for a hundred yards or more along the sides of the cliff. As these caves afford convenient places of shelter, they have been occupied as residences by the inhabitants of the valley at many different periods, but more particularly by a race of prehistoric Troglodytes, who form the subject of the present work.

The presence of these people is indicated by successive layers of *débris* beneath the present floors of the caves denoting successive periods of occupation, and separated from each other in some places by a coating of stalagmite of considerable thickness. The small distance of some of the caves above the river proves that the latter can have deepened its course but little, if at all, since the caves were occupied by prehistoric men; the cave of La Madelaine, in which numerous works of art of the Troglodytes have been found, is but little above the level of extraordinary floods of the river at the present time, whilst those of Le Moustier and Les Eyzies are 90 and 100 feet respectively above the river. The position of the caves, consequently, affords little or no evidence as to the age of their contents, which has to be determined in two ways, firstly, by the associated animal remains; and secondly, by the nature of the relics of human workmanship. From both of these sources we derive proof of the greater antiquity of the Le Moustier cave than those of La Madelaine, Les Eyzies, and Laugerie Basse, in the same valley.

Comparing the fauna of these caves with that of other well-known finds of the prehistoric era elsewhere, we find that the following sequence has been established. Summarising briefly, and omitting for the sake of clearness many details which ought, nevertheless, to have weight in a full consideration of the subject, the following are the animals, the remains of which are most prevalent in the different prehistoric periods. In the Drift, the mammoth, rhinoceros, horse, and ox, are the predominant animals, and the reindeer appears but sparingly. In the cave of Le Moustier the mammoth and reindeer are both found, but the latter is still found sparingly. In the other caves of the valley the same fauna is found, but the remains of the reindeer are abundant, and these caves are consequently attributed "par excellence" to the reindeer period. In the kitchen middens of Denmark both mammoth and reindeer are absent, and the class of domestic animals is represented only by the dog. In the oldest of the Swiss lake villages the mammoth and reindeer are also absent, although they existed formerly in the neighbourhood, as shown by the contents of the caves, and domestic animals are abundant. Both mammoth and reindeer are wanting in all the tumuli and other prehistoric monuments of the Celtic period, in Gaul, showing that they must have disappeared from this part of Europe before that time.

Turning now to the relics of human industry, we find a corresponding sequence in the different ages. In the Drift, none but the large, rude, flint tools known as the Drift type are found. In the cave of Le Moustier these large rude tools are also found, and here only amongst the caves of the valley, and they pass gradually into another form known as the side tool or scraper, which is also wanting in the later caves, where they are replaced by lance heads of finer make and finish. In these also, carved harpoon heads of bone begin to appear, and engravings of the mammoth and reindeer, scratched by the hand of man on fragments of horn and bone. No pottery or ground axes are found in any of the caves, nor was the art of spinning known. In the Danish kitchen middens, ground axes are found, though rarely; pottery is frequent, and the art of spinning in some form appears to have been introduced. In the oldest of the Swiss lake habitations, ground axes and pottery are abundant; spinning, weaving, and the cultivation of wheat was well known.

From the study of their arts we are led naturally to inquire into the physical peculiarities of the inhabitants of the caves; on this point, however, our evidence is somewhat meagre. Skulls of a brachycephalic type, and others approaching to that form, had led Dr. Pruner-Bey to attribute the inhabitants of France of the reindeer period to a Mongol origin, but in these caves we are introduced to a race of men whose form of cranium is decidedly dolichocephalic. In the valley of the Vezère at Cro-Magnon not far from Les Eyzies, a cave was discovered and explored by M. Louis Lartet, which contained the remains of four individuals. These remains were situated at the back of the cave, above a series of deposits which marked successive periods of the occupation of the cave, and the whole cave had been filled up by a talus which had fallen from above. The animal remains found in the relic beds of the cave consisted of bear, mammoth, lion, and horse. Reindeer was also found but in small quantities, and this circumstance, coupled with the absence of carved or engraved bone, led

the explorers to attribute the find to the earliest cave period. The position of the human remains, however, above the relic beds would, as Mr. Boyd Dawkins has shown in his work on "Cave-Hunting," be sufficient to throw doubt on their contemporaneity with the other relics of the cave were it not that skeletons have been since found in other caverns in the valley, and more particularly in that of Laugerie Basse, in positions which make it certain that they are of the age of the works of art found with them, and these skeletons correspond in their osteological peculiarities with those of Cro-Magnon. In both places the skulls are dolichocephalic, and both afford instances of men of large stature having platycnemic tibias, one of those from Cro-Magnon being, according to Boyd Dawkins, the extremest case of platycnemism on record. We have therefore good grounds for believing that markedly different types of mankind existed in the south of Europe during the reindeer period. This result has been held by polygenists to afford satisfactory confirmation of their views, but we may be permitted to doubt the validity of such conclusions. If, as has been suggested by Prof. Huxley, this part of Europe was occupied in the earliest times by a race of Melanochroi, consisting of a mixture of the dark long-headed race of the south with the fair and presumably short-headed race of the north, it is evident that types as divergent as any that are to be found at the present time must have existed amongst the earliest known inhabitants of this region. A long previous period of geographical separation under different climatic conditions would be sufficient to give permanence to varieties as distinct as any that have been brought to light by the researches of Anthropologists. We are far from believing that the reindeer period has carried us more than a short way towards the origin of the human race.

Since the explorations of Messrs. Lartet and Christy were brought to a close, another chapter has been added to the history of the reindeer period by the discovery of Mr. Conrad Merk in the cave of Kesslerloch, near Thayngen, in Switzerland; the value of this discovery is greatly enhanced by its vicinity to the relics of the later inhabitants of the lakes. Had the lake habitations been occupied at the same time as the cave, evidence of connection must undoubtedly have been found, but the contents of the cave point undeniably to a period contemporaneous with the remoter Troglodytes of the Dordogne. Amongst the fauna the presence of the mammoth, rhinoceros, cave-bear, lion, and reindeer are alone sufficient to warrant this conclusion, whilst at the same time the works of art show a most remarkable resemblance to those of the French caves, and an equally marked contrast to those of the oldest of the Swiss lake villages. The carved harpoon heads of bone, the absence of pottery, the presence of deer-horns perforated with large holes bored from both sides, the use of which is unknown, and above all the engravings of animals, especially the reindeer, upon the horns of those animals, show that a condition of culture corresponding to that of the Dordogne people must have existed here.

Opinions differ as to which of the two localities have produced the highest types of art; the difference of style observable in the engravings is such as might be expected to exist amongst remote tribes, but the resemblance, when compared with the productions of other races of savages is no less remarkable.

One of the engravings, attributed to the cave at Kesslerloch, calls for a few remarks. Of the genuineness of the relics discovered in this cave, no doubt has been entertained, with the exception of two. One of these, said to have been found by a workman in a heap of rubbish after the excavations had been completed, and under circumstances which gave rise to suspicion, represents a fox drawn front view, with the hind quarters foreshortened. The specimen has been placed in the Christy collection in Victoria Street, not as a genuine relic of the cave, but for convenience of future reference. It is worthy of observation that in all the genuine engravings from the caves of both places the animals are invariably drawn with a side view, and generally following each other in the same direction, much as a child might have drawn them, and the same peculiarity is often to be noticed in the bone engravings of the Esquimaux. The forger of Kesslerloch was no doubt not aware of this, or a feebler exercise of his artistic talent would have served him in better stead. He has, however, done good service by drawing attention to the fact that the fore-shortening of a figure represents a phase of art at which the men of the reindeer period had not arrived. Surprise has been expressed by many at the truth and freedom of some of these designs, appertaining to so remote a period of man's history; but when we consider how early the power of drawing animals is shown by many of our own children, and how much pleasure they take in exercising it, we need not wonder that a great development of the faculty of imitation should be found to exist side by side with the proofs of a low condition of culture. Upon the whole we see nothing in these or any of the prehistoric discoveries of our time to weaken our faith in a slow but continuous progression from lower to higher forms of art and industry.

THE BOTHKAMP SUN OBSERVATIONS

Beobachtungen angestellt auf der Sternwarte des Kammerherrn von Bülow. Heft III. Edited by Dr. O. Lohse.

WHOEVER knows the good work that has been done at the Solar Observatory at Bothkamp will hear with regret that the observatory has ceased to exist. It seems that the work was discontinued as soon as Dr. Vogel left it to take his place in the new observatory of Berlin. The history of M. von Bülow's observatory is a fresh proof that work which requires long and continued observations cannot be made dependent on the generosity of a single man, but must be carried on by the State; yet everybody will join in Dr. Lohse's hope that the proprietor of the observatory, to whose liberality we are indebted for the observations made during many years, by Dr. Vogel and Dr. Lohse, and for their publication, will decide to continue his generous and useful work at a future time.

In two previous parts Dr. Vogel has given us the results of his observations, and we are promised a fourth part containing some further researches of his. The third part, which has just appeared, contains the work done by Dr. Lohse.

The paper consists in great part of tables containing

his observations. The list of sun-spots at the end of the publication and the various extracts from the note-book will prove very useful to those who are engaged in researches of a similar kind. The observations seem to have been conducted with great care, and Dr. Lohse gives us in every case the exact method by which the measurements have been made.

If we endeavour to review a work which is not being continued, at least for the present, we rather turn to the actual results of the observations than to a mere list of accumulated facts. This list, no doubt, may prove hereafter to be the most important part of the work, yet it is only made important by those who discuss the observations. The more doubtful and hypothetical part, containing the conclusions, is therefore the better test for the moment, for we must not forget that without a guiding idea a mere tabular arrangement of facts is useless.

One of the most curious results of Dr. Lohse seems to be the discovery of a period of fifty days in the eruptive activity of the sun. Dr. Lohse took from the drawings of protuberances published by the Spectroscopic Society of Italy, the area of the protuberances as shown in the drawings for each day, and made a curve in which the times of observation formed the abscissæ and the area of the protuberances the ordinates. This curve first shows maxima and minima corresponding to maxima and minima of sun-spots. It next shows a short period of fifty days. During the years 1871, 1872, and the beginning of 1873, this period was well marked. From the middle of 1873, however, the whole solar activity became so small, owing to its chief periodicity of eleven years, that these secondary maxima cannot any more be distinguished.

We turn now to the spectroscopic observations, in which Dr. Lohse was led to somewhat similar conclusions as Mr. Lockyer. It is a well-known fact, that while nearly all the elements standing at the positive end of the electro-static series are found in the sun, we have as yet obtained no decided evidence of the more electro-negative elements. On the other hand, it is not probable that the sun should not contain so many bodies which play an important part in our world. Both Mr. Lockyer and Dr. Lohse came to the conclusion that we must look in the outer and cooler layers of the sun's atmosphere for evidence of the metalloids, but while Mr. Lockyer assumes that they exist as well in the hotter parts of the solar envelope, but under such conditions that we cannot identify their spectra, Dr. Lohse assumes that they do not exist except in the outer layers of the corona. Dr. Lohse is thus forced to assume a force in the sun which drives all the more electro-negative elements away from its centre. This is an hypothesis which we cannot accept, unless we have independent evidence in its favour, or unless it is the only one which will account for the facts; just as we could not accept Mr. Lockyer's hypothesis, if we had no evidence of changes in spectra produced by variations of temperature and pressure. Mr. Lockyer's hypothesis has a decided advantage over that of Dr. Lohse, for we have recently obtained such strong proofs of the changes of spectra produced by a variation of temperature and pressure, that we cannot help thinking that, had Dr. Lohse been acquainted with all these recent experiments, he would have come to the same conclusion as Mr. Lockyer. This conclusion, indeed, seems inevitable, if it is once assumed that the metalloids really exist in the sun. It is important to mention that this presence of metalloids in the sun is rendered still more probable by the fact that the red and most likely cooler stars give spectra containing fluted bands.

It is interesting to notice that Dr. Lohse finds many of the unknown dark lines contained in the blue end of the solar spectrum to be reproduced in the spectrum of α Herculis, and although weaker in that of α Orionis, while they are absent in that of α Bootis.

Dr. Lohse does not seem to arrive at any results differing much from those of other observers in his observations on faculæ and sun-spots. It is a matter of regret that he, most likely for the sake of brevity, does not enter more fully into the explanation of his own views. A discussion of ideas described in such a cursory manner is impossible, as such a description is necessarily incomplete.

We hope that Dr. Lohse will have occasion to follow out his researches, and do not doubt that he will be rewarded by most interesting results.

ARTHUR SCHUSTER

OUR BOOK SHELF

The Absorptive Glands of Carnivorous Plants. By Alfred W. Bennett, M.A., B.Sc., F.L.S., Lecturer on Botany at St. Thomas's Hospital. Read before the Royal Microscopical Society, Dec. 1, 1875. With one plate.

MR. BENNETT notices the occurrence in *Drosera rotundifolia*, *Pinguicula vulgaris*, and *Callitriche verna* of peculiar bodies, which at first sight might be mistaken for stomata, and consisting of two nearly hemispherical cells filled with protoplasm. Each of the hemispheres contain a darker nucleus-like spot, and each is surrounded by a thin-walled cell containing chlorophyll. From these hemispherical bodies are developed the papillæ with thin walls and containing chlorophyll. *Drosera* and *Pinguicula* are carnivorous, and Mr. Bennett suggests that *Callitriche* may also be carnivorous, from the occurrence of these peculiar bodies. It seems probable that they are really as Mr. Bennett thinks, absorptive glands, and they certainly bear a strong superficial resemblance to the quadrifid processes found and described by Darwin in *Utricularia* and *Genlisea*. The subject is a very interesting one, and it is to be hoped that further research will throw more light on the matter. It is rather difficult to get a clear idea of the structures from the plate, which seems a little out of drawing, and rather confusing.

W. R. MCNAB

Reseña de las Rocas de la Isla Volcánica Gran Canaria. Por Don Salvador Calderon. (Reprinted from the Anales de la Sociedad Española de Historia Natural. Tomo iv.) Madrid 1876.

IN this work, which is appropriately dedicated to M. Berthelot—to whom we owe one of the earliest descriptions of the geology of these interesting islands—the author gives some valuable information concerning the relations of the different classes of volcanic rocks to one another. He also describes some of the vast "Calderas" or craters so characteristic of this group of islands, and notices the theories which have been proposed to account for their origin. Of especial interest, however, is the account which he furnishes of the nature and composition of the different varieties of volcanic rocks, and the classification which he proposes for them. It would appear from this work of Señor Calderon, that the true or "sanidine-

trachytes" have not yet been found in these islands, but that the predominant felspathic constituent of the more acid rocks is always plagioclastic. Hence they are described under the names of Andesite, Trachy-dolerite, and Trachy-diorite. The first of these would appear, from the definition given, to correspond with the well-known lavas of Hungary, the last to resemble the green-stone trachytes or "propylites" of the same country. These trachytic rocks are found to assume at times a vitreous character, thus passing into obsidian; and they occasionally exhibit the perlite modification of structure. The basaltic rocks, noticed by the author, do not appear to offer any features of special interest.

La Biologie. By Dr. Charles Letourneau. Bibliothèque des Sciences Contemporaines. (Paris: C. Reinwald et C^ie^., 1876.)

THIS small work within five hundred and fifty pages gives a concise description, in a popular form, of the phenomena exhibited by living organisms. "C'est une œuvre de vulgarisation," intended for the commencing student and the amateur. Such being the case many important facts have to be omitted, and much has to be embodied in a general form. As in most works many of the broad statements are apt to mislead. It is all very well to say, as does Dr. Letourneau, that the heart is trilocular in the reptiles and quadrilocular in birds, but considering the nature of that organ in the crocodiles, we think its nature in them ought to be mentioned. The title of the work is so all-embracing that we think it can hardly be justified by its contents. Morphology as well as physiology, together with the principles of evolution and classification, are all parts of "biology," nevertheless in the work before us morphology, and the immediate dependents of that science, are not touched upon. A more fitting title would have been "Comparative Physiology, Vegetable, and Animal." Several illustrations are introduced, and these are well selected, most if not all from other works. The descriptions are clear and concise, many too short to be of much service except as a first-book.

Algebra for Beginners. By James Loudon, M.A., Professor of Mathematics and Natural Philosophy, University College, Toronto. (Toronto, 1876.)

THIS work is an elementary one, taking the usual subjects up to and including Quadratic Equations. There is a chapter on Exponential Notation, giving a fair exposition of the Theory of Indices. There is nothing noteworthy in the execution: it is quite on a par with many similar text-books in this country, so that the chief point of interest is the information it gives us as to what instruction is given in the subject to the rising generation in Canada. The use of *mononomial* strikes us as being affected. The work is exceedingly correctly printed. There are but six mistakes, we think, in the whole book, three of which are in the answers (xv. 3, xxxvii. 14, li. 16). Many of the questions are traceable to English sources.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Coloured Solar Halos

IN his interesting scientific notes taken in the Himalayas, and printed in the last number of NATURE (p. 393), Dr. Arthur Schuster mentions the frequency of the occurrence, in India, of rainbow-coloured rings round the sun, and states that he has only once seen this phenomenon in England. The apparition of a complete iridescent circle is no doubt rarely seen, but I have, since the winter of 1873–74, when I first observed them, so frequently seen fragments of such rings both in Switzerland and in England, that their non-occurrence, when thin white clouds are near the sun, seems to me to be the exception rather than the rule. In this country, and generally at low elevations, they are not easily detected by the unassisted eye, but in the high Alps both in summer and winter I have rarely failed to see them, when the sun and a thin white cloud were at the necessary distance from each other; they are, however, much more easily observed when the eye is protected from the glare by the neutral tinted glass which is frequently used for snow spectacles. The first and most vivid iridescent halo I ever saw, appeared projecting from the side of a mountain from behind which the sun was about to rise, near the summit of the Fluela pass, and about 7,000 feet above the sea. This was in the winter of 1873-74, and the thermometer stood at 19° Fahr. Last August and the first half of September I saw them almost daily on the Riffelberg and at Pontresina, and I have repeatedly noticed fragments of iridescent rings during the past autumn and winter in crossing Kensington Gardens about 9.30 A.M. In London, however, the blue and green rays are rarely visible, owing no doubt to their absorption by the murky atmosphere, whilst the orange and red rays easily reach the eye. On Sunday last, with snow upon the ground, I saw, through neutral tinted glass, the orange and red of the halo as the thin edges of clouds approached, or receded from the sun, and on Monday I distinctly saw the green also.

I hold these coloured halos to be a decisive proof of the frozen condition of the clouds in which they appear; firstly, because the cloud seen on the Fluela pass, when the thermometer was 13° below the freezing point, must have been frozen; and secondly, because I have repeatedly seen a portion, at least, of the lower half of the iridescent circle in the high valleys of Switzerland by looking along a field of snow sloping upwards towards the sun, and when the thermometer indicated temperatures varying from $-15°\cdot5$ Fahr. to $+23°$ Fahr.

It would be worth while to have the occurrence or non-occurrence of these halos daily recorded in our meteorological observatories, as indications of the temperature of the air at great altitudes. E. FRANKLAND

On the Evidences of Ancient Glaciers in Central France

IN NATURE, vol. xiii. p. 31, Dr. J. D. Hooker gives some notes of traces of ancient glaciers in Central France, especially in the Mont Dore, and in a following short letter (p. 149 of the same volume), in reference to this notice of Dr. Hooker, the late Mr. G. Poulett Scrope, the celebrated describer of the volcanic regions of that country, calls in question the exactness of Dr. Hooker's observations. Dr. Hooker in a subsequent letter (p. 166) insists upon the correctness of his views, which he seems to believe original and never before advanced. Neither Dr. Hooker nor Mr. Poulett Scrope seem to have known that I have already, in a paper published in the *Ausland* (1872, Nos. 20 and 21, pp. 460 and 512) entitled, "Erosions und Gletscher wirkungen im Mont Dore, &c." described the traces of glaciers to a still greater extent than even Dr. Hooker does. Not only did I name the place in question (which is situated just at the entry of the Gorge d'Enfer, upper valley of Mont Dore) and describe it as an ancient frontal moraine of a glacier, but I have also given the view of the late Prof. Lecoq (who was never an Abbé as Mr. Poulett Scrope seemed to believe), who says in reference to this locality, *that if ever a glacier had existed in Mont Dore it must have been in this valley.* But besides this point, which in itself is decisive, I noticed a great number of other localities affording examples of polished rocks, transported and rounded blocks, stone lines, and other evident traces of glaciers, which I will not re-enumerate, as they may be found in my above-mentioned paper.

It is quite clear that Mr. Poulett Scrope was in the wrong in denying that those signs in the Mont Dore are the effects of glacial action, but on the other hand, I must, in justice to myself, courteously remind Dr. Hooker that I have the priority in describing those marks as glacial traces which Lecoq interpreted as water-flood traces. I may say in conclusion that this learned geologist of Central France (Lecoq) personally turned my attention to those phenomena while visiting the Auvergne in 1867, and seemed inclined to accept my interpretation.

Breslau University, Prussia, March 10 A. VON LASAULX

The Uintatherium

IN the abstract of my lecture published in NATURE, vol. xiii., p. 387, it is stated that "the first discovered evidences of the

existence of animals of this group were described by Leidy, in 1872, under the name of *Uintatherium*."

Intricate questions of priority, such as those in which the nomenclature of many of the recent American palæontological discoveries is unfortunately involved, cannot be discussed and settled in brief abstracts; but I see that the above statement conveys a wrong impression, which I shall be glad to correct. Bones of some of these animals were discovered by Prof. Marsh and Lieut. Wann, of the Yale College exploring party, near Sage Creek, Western Wyoming, in September 1870, and described by the former in the following year (*American Journal of Science and Arts*, July 1871, p. 351), though referred provisionally to the genus *Titanotherium*. There seems, however, to be no doubt that Leidy's name, *Uintatherium* (*Proceedings of the Academy of Natural Sciences*, Philadelphia, 1872, p. 169; read July 30, published August 1), was the earliest of the new generic designations applied to any of the group, and therefore ought to be adopted for the whole, until it is clearly shown that any sufficiently important distinctions exist between them to warrant their separation into different genera.

March 18 W. H. FLOWER

Morell's "Euclid Simplified"

IT is only quite recently that my attention has been directed to the review of "Euclid Simplified" in NATURE, vol. xiii. pp. 201–204. I shall endeavour to condense my reply to the criticisms contained in that review as much as possible, taking them in the order in which they occur, which will simplify the controversy.

And firstly, it is objected that "the title 'Euclid Simplified' is a misnomer, for the method of Euclid (the geometer) is departed from altogether." I reply by explaining that by far the greater part of the theorems and problems, and also the method followed throughout in "Euclid Simplified" are taken directly from Amiot's "Éléments de Géometrie" (15th edition, 1873). In his preface to another work, "Leçons Nouvelles de Géometrie Élémentaire" (1865), Amiot says: "Les éléments de géometrie que nous venons de réimprimer et cette séconde édition des Leçons nouvelles de géometrie, sont deux ouvrages différents. Le premier n'est que l'exposé de la géometrie des anciens; le second est un essai de géometrie générale, c'est-a-dire qu'il comprend *non seulement les éléments* d'Euclide, mais encore les principes de la géometrie moderne, qui est resumée et, pour ainsi dire, personnifié dans les travaux de M. Chasles, notre géometre par excellence." I infer that in adopting and following Amiot's "Elements," I have followed the ancients and Euclid, though shortened and simplified.

At a subsequent part of the review the writer is exposed to severe animadversions for his intention to produce what is represented to be an epitome of the brilliant discoveries of M. Chasles. This matter can also be set at rest by referring to the extract from the preface of M. Amiot, previously given. Mr. Morell has only projected a compilation and translation from Amiot's "Leçons Nouvelles," and from Rouché and De Comberousse (1ère Partie. Géometrie Plane. Appendice), also treating of modern geometry.

Passing from the title to the contents, I admit that the typographical errors are unfortunately numerous, nor is it possible to avoid this except by employing the best and most expensive printers. The misprints *maner* and cord, the omission of the word "side" before "of the equilateral triangle," and the passage relating to the quadrilateral $A\ B\ C\ D$ must be referred to this category. The latter passage is translated from Legendre (edition 1868 [not 1872], p. 78), and requires the fourth side $A\ D$ to be added, which has been omitted by the printer. For "without changing" read also "thereby changing"—in this case I confess an oversight of the writer.

I proceed next to meet the strictures of the reviewer relating to Gallicisms and the use of terms new to boys. In defence I might point to the Hellenisms and Latinisms in our School Euclid, and affirm that Gallicisms are more nearly akin to modern English.

I content myself with pointing to the employment of terms, condemned in "Euclid Simplified," by writers of approved excellence, including Gerard's "Elements of Geometry." It is objected that I write, p. 168, "The centre of similitude is the meeting-place." I find at p. 36 of Mr. Gerard's "Elements of Geometry," "The meeting point of two lines." . . . Again the terms "perpendicular to the centre, perpendicular to the middle," censured in "Euclid Simplified," ought to be taken in connection with the ensuing words: "to the centre of the straight line $A\ A'$" and "to the middle of $A\ B$." Thus amplified, the terms agree with those used by Mr. Wormell—"perpendicular to $D\ E$ at its middle point C." "The perpendiculars to the sides of a triangle at their middle points." ("Modern Geometry," pp. 78–81.)

Before I dismiss this question of terminology, I wish to suggest that recent works on geometry in high repute, especially those I have just named, introduce very fully terms with which boys are not at all acquainted, and which are new in English. I briefly enumerate a list of these new importations: Escribed, exscribed, explements, intercepts (used as a noun), circumscriptible, intangence, bisectrix, extangent, median, a plane lune, octant, and many more which cannot be introduced here for want of space.

Considering the further criticisms, I beg to explain that no notice of the Association for the Improvement of Geometrical Teaching was inserted in the preface because absence from England and ill-health had severed me from all knowledge of its proceedings and of its Syllabus.

If the enunciations are loosely and inelegantly worded, Amiot must bear the blame which attaches in a greater degree to our translations of Euclid.

Further, the objection made to my use of the terms "capable angle" must extend to the use of the same term in Gerard's "Elements," p. 310.

In the definition of the parallelogram the printer has omitted "and parallel," words which I find in my MS. The term lozenge is used as synonymous with rhombus by Wormell ("Elementary Course of Geometry," p. 65), and Gerard, p. 235. The definition of the circumference is that of Amiot ("Elements," p. 40) and Gerard (p. 76). That described by the reviewer as the common school-boy definition is Wormell's, p. 28. The expression "a circumference is generally described in language by one of its radii" is thus given in Amiot: "On designe ordinairement une circonférence par l'un de ses rayons." I shall pass over the criticisms about "the" and "a" as too minute, also the remark about major and minor arcs met by Def. 36. Problem VII. shows any boy of ordinary intelligence how to bisect a line.

Derivation in notes is not treated syntactically, and can also be dismissed. But the remarks of the critic about the use of R as meaning right angle are met by referring to Wormell's (p. 173) use of $G\ C\ M$ as greatest common measure. The term pentedecagon is used by Gerard (p. 202). The proof of the ratio of two rectangles $\frac{R}{R'}$, is Legendre's; and at p. 67, after showing that $\frac{R}{r} = 4$, he adds: "Ainsi le rectangle R contient quatre fois le rectangle pris pour unité" (*i.e.*, r). This conclusion in my book is criticised.

The reasoning to Theorem VI. (p. 148), which is called defective in the review, only errs by excess of proof. I have little more to add. The "Essentials of Geometry" are almost entirely a translation of a useful Spanish work by noted mathematicians.[1] The 205 exercises are throughout from Amiot, and as these 205 exercises are *literally* all from Amiot, it is a serious charge to say, like the reviewer, that many of them are objectionable in geometry. In Exercise 30 "a" quadrilateral is a misprint: read "this."[2] J. R. MORELL

"Weight" and "Mass"

THE correspondence which has recently appeared in NATURE on this subject has great interest for those engaged in teaching Physics. I confess I regretted to learn that "gravity" had been diverted from its long recognised meaning in science—that pointed out by Mr. Stoney—at Glasgow, to be employed for one of the meanings of the word "weight." The symbol "g" is "gravity" represented by its initial letter, so that if the meaning of the word be changed, consistency would require that the symbol should be altered. I find, practically, no difficulty in restricting the word "weight" to the sense of force, insisting on the use of the phrases "mass of so many pounds, ounces, or grammes," and "force equal to the weight of a mass of so many pounds, grammes," &c.; for which, after some time, I allow the use of the phrase, "*the* weight of so many pounds."

On another point of nomenclature I would suggest that those who, like myself, think it necessary to use the British units coordinately with the metric, should adopt some analogue to the

[1] Their names will be given when I recover the book or get another copy.

[2] The work of Mr. Wormell to which reference is made in this letter is (with one exception) his excellent "Modern Geometry," published by Murby.

dyne. I use *vis* (pl. *vires*) to express the absolute unit of force in the F. P. S. system of units, with the multiples *decemvires*, *centivires*, *millivires*. Thus nine *centivires* is very closely equal to the weight of twenty-eight pounds in this country.

I should add that the distinction between "weight" and "mass," generally recognised, but not uniformly insisted on in practice, is clearly pointed out in Prof. Everett's useful tables.

University Hall, March 18 J. J. WALKER

The Dry River-beds of the Riviera

THOSE who have visited the Riviera of Piedmont will remember as one of its most remarkable features the broad stony river-beds, sometimes with a meagre rill trickling down a narrow channel in the middle, sometimes entirely dry, but never with any body of water sufficient to account for the immense bed; the Paglione at Nice, with its bed spanned by a bridge of three broad arches, and with a stream never more than four or five feet wide and a few inches deep, is a specimen of what I mean. Can any of your scientific readers tell me what and when was the change of climate which caused what must once have been large rivers to shrink into mere rivulets? To all appearance it must have been within historical times, as the river-beds are distinct and still bare, without any encroachment of vegetation. Probably the simplest way of accounting for the phenomenon would be, by showing that there has been a great diminution in the snow lying on the Alpes Maritimes, which are drained by these rivers. It is remarkable, too, that in many of the narrow valleys running up into the hills, now quite dry, there are evident traces of torrents and waterfalls apparently in recent times. R. E. BARTLETT

Nice, March 7

The Ocelli in Insects

AT vol. xiii. p. 168, H. Müller calls the attention of entomologists to a subject which has interested other entomologists before—the function of the ocelli in insects. With due deference to a suggestion made by such an authority, it seems to me that the size of the ocelli in hymenopterous insects is not dependent on their nocturnal habits. Why in hymenoptera more than in other orders? Indeed, it may be doubted whether in some insects the ocelli are organs of vision at all, or at least whether they are of any practical use as such in the imago. Their number, as well as size, differs in different species of the same order, seemingly without regard to their habits, whether diurnal or nocturnal, and in many moths they are so completely concealed by the scales that it is necessary to divide the head to ascertain whether they are present or absent, so that it is difficult to understand how they can be of any service as organs of vision. May they not in the imago, in such cases, be merely functional remnants of larval organisations. C.

Colorado, Feb. 15

The Recent Storm

YOUR meteorological readers will probably guess that I have made an error of an inch inadvertently in the barometer readings of Sunday week. Also the last line should contain "nine hours" in place of seven. T. S. USBORNE

Staplehurst, Kent, March 21

OUR ASTRONOMICAL COLUMN

STRUVE'S COMPANION OF PROCYON.—Mr. Otto Struve, in his remarks at the Royal Astronomical Society, in May, 1874, upon the later Pulkowa observations of the faint companion to Procyon, which he discovered on March 19, 1873, and which has been supposed to account for the anomalous motion of the latter, established by the researches of Prof. Auwers, referred to the circumstance of the small star not having been up to that time perceived with the 26-inch refractor of the Washington Observatory. Admiral Davis, the present superintendent of this establishment, has communicated to the *Astronomische Nachrichten*, the particulars of observations principally instituted for the purpose of confirming the existence of Struve's companion. The observations were commenced in November 1873, and have been continued to the beginning of the present year. On no single occasion have Professors Newcomb and Holden, the usual observers, or any one who has examined the star with the 26-inch refractor, been able to detect a companion in the position assigned by the Pulkowa measures. Close faint stars have, however, been remarked in other position-angles, about three of which it is stated no doubt is entertained:—

1. Position about 10°	...	Distance	6″
2. „ ... 36°	...	„	8″·8
3. „ about 50°	...	„	less than 10″

And it is said to be quite possible there may be one or two more. No. 2 is the most readily visible.

Mr. O. Struve's measures gave the following mean results:—

1873, March 28 ...	Position 90°·24 ...	Distance 12″·49
1874, April 10 ...	„ 99°·60 .	„ 11″·67

How then is the contradictory character of the Pulkowa and Washington observations to be accounted for? It can hardly be, as suggested by Mr. Struve, that "the surpassing brilliancy of the principal star may have hindered the recognition of the small companion in its neighbourhood," since notwithstanding it does not appear that a smaller aperture than 22 inches was employed during the Washington observations, three closer companions were considered to be certainly in existence. There remains the supposition of variability of light of the Pulkowa companion, if difference of atmospheric circumstances be ignored as inadequate to explain the want of success of other observers in detecting it.

Nothing more is heard of the Smythian *orange-tinged* eighth magnitude distant from Procyon in 1833, 145″ on an angle of 85°. As is well known, the only observation confirmatory of the existence of this star is that by Mr. Isaac Fletcher, M.P., early in March, 1850, which gave for the position 84° 19′; most unfortunately the distance was not measured, because there is a star of similar brightness on very nearly the same angle but at a distance of about 330″ measured by Capt. Jacob, Mr. Powell, and the late Lord Wrottesley. Anyone, however, who reads Mr. Fletcher's letter to Admiral Smyth, printed in "Sidereal Chromatics," p. 69, will see that there is little doubt the object observed in 1850 was the same that was measured, or rather estimated, as to position in 1833, the difference of distance not admitting of a mistake on the part of an experienced and careful astrometer. The more distant star was judged to be blue by Mr. Powell; the orange-tinge recorded in "the Cycle" is a characteristic of a large number of the known variable stars.

THE TOTAL SOLAR ECLIPSE OF 1883, May 6.—In this eclipse, in which the duration of totality where the sun is near the meridian will exceed five minutes, the course of the central line appears to be a most unfavourable one for observation, being almost entirely a sea-track. The elements are very approximately as follows:—

Conjunction in R.A., May 6, at 9h. 44m. 42s. G.M.T.

R.A.	43°	30′	52″	
Moon's hourly motion in R.A.		38	23	
Sun's „ „ „		2	25	
Moon's declination	16	11	32	N.
Sun's „	16	37	53	N.
Moon's hourly motion in decl.		7	26	N.
Sun's „ „ „		0	42	N.
Moon's horizontal parallax		60	52	
Sun's „ „		0	9	
Moon's true semi-diameter		16	35	
Sun's „ „		15	51	

Hence the central and total eclipse begins upon the earth in longitude 156° 1′ E. of Greenwich, and latitude 34° 43′ S., and ends in longitude 86° 44′ W., and latitude 13° 41′ S.; the eclipse is central with the sun on the meridian in 147° 4′ W., and 9° 11′ S. The following are also points upon the central line:—

Long.	Lat.	Long.	Lat.
179° 51′ E. ...	25° 43′ S. ...	139° 51′ W. ...	6° 53′ S.
168 19 W. ...	19 52 S. ...	137 44 W. ...	6 24 S.
160 49 W. ...	15 49 S. ...	119 52 W. ...	5 51 S.
140 46 W. ...	7 8 S. ...	108 12 W. ...	7 51 S.

By a direct calculation for a point 140° 46′ W., 7° 8′ S. in the longitude of the Marquesas, totality is found to commence at 0h. 39m. 30s. local mean time, duration 5m. 15s., the sun at an altitude of 64°.

THE MINOR PLANETS.—The four older minor planets, Ceres, Pallas, Juno, and Vesta, are now in pretty favourable positions for observation, and Vesta, which will be in opposition on the 28th inst., is very little below an average sixth magnitude in brightness, and may probably be detected without the telescope by those who are gifted with strong sight and are acquainted with the planet's position with respect to stars in the vicinity. On the 28th it will be a very little to the left of the line joining δ and ϵ Virginis, and nearly equi-distant from these stars, which are of the third magnitude.

Niobe, like Euphrosyne, is occasionally situate at a considerable declination. At the beginning of November next she nearly attains 53° N. in the constellation Camelopardus. An observer who may chance to meet with a small star which he has not before seen at a great distance from the equator, must not too hastily conclude that it belongs to the list of variables.

No. 160 was discovered by Prof. Peters at Clinton, U.S., on the morning of Feb. 21; it has been observed at Marseilles by M. Borrelly.

ON THE ACTION OF LIGHT ON SELENIUM

On the 18th of last month Dr. C. William Siemens gave a lecture to the members of the Royal Institution on the above subject.

Commencing with a general reference to light as a natural force, he showed how little the potential action of light made itself evident to our senses, as with the disappearance of the light its effects seemed entirely to vanish; he then showed a temporary effect of light by its action on phosphorescent salts, which continue to glow for a long time after the source of light is removed, and drew attention to the permanent effect produced by the decomposition of the salts of silver in photography. He next referred to the radiometer, Mr. Crookes' little machine for illustrating light effects, which he brought forward for the purpose of showing the motive power of light, and closed his introduction by a reference to some experiments which he had made on a fungus that lives in the dark, and which, on analysis, gave no evidence of containing carbon, thus helping to favour the hypothesis *that it is not heat, but the ray of light which breaks up carbonic acid in the leaves of plants in order to separate the carbon.*

Selenium was discovered in 1817 by Berzelius, as a bye product from the distillation of iron pyrites. It is fusible, combustible, and similar to sulphur, phosphorus, and tellurium. If melted (at 217° C.) and cooled rapidly, it presents a brown amorphous mass of conchoidal fracture, and is a non-conductor of electricity; if heated only to 100° C., and retained for some time at this temperature, it becomes crystalline, and is a slight conductor of electricity, the conductivity increasing with battery power, and varying according to the direction of the current, as lately observed by Prof. Adams.

It was on the 12th of February, 1873, that the Society of Telegraph Engineers received a communication from Mr. Willoughby Smith, one of its members, of an observation made first by Mr. May, a telegraph clerk at Valentia, viz. that a stick of crystalline selenium offered considerably less resistance to a battery current when exposed to the light than when kept in the dark; this was corroborated by the Earl of Rosse, who clearly proved the action to be due *solely* to light, and who also showed the effects of the light of different portions of the spectrum, and afterwards by Lieut. Sale, and conjointly by Messrs. H. N. Draper, F.C.S., and R. J. Moss, F.C.S.

About twelve months ago the matter was again taken up by two independent observers, Prof. Adams in this country, and Dr. Werner Siemens in Germany, and it was to the results obtained by the latter, and which have been communicated to the Academy of Sciences of Berlin, that the lecturer's remarks were chiefly confined.

The sensitive selenium plates made by Dr. Werner Siemens, with which experiments were made, are formed of two spirals of platinum wire, laid upon a plate of mica, in such a manner that the two wires run parallel without touching; upon the plate a drop of molten selenium is allowed to fall, and before solidifying, another plate of mica is pressed down; the two protruding ends of wire serve to insert the selenium element in a galvanic circuit. Amorphus selenium when thus tested produces no deflection of the galvanometer, either in light or darkness. If, however, a selenium disc which has been kept for some time at 100° C. and then cooled is inserted, a slight deflection of the galvanometer takes place when it is under the influence of light, but none in darkness. If now a selenium disc which has been kept for several hours at a temperature of 210° C., a point below that of the fusion of selenium, and which has been gradually cooled, is substituted for the other, a considerable deflection under the influence of light will be observed, whilst a hardly perceptible deflection takes place in the dark.

It was also explained, as the result of an experiment, that amorphous selenium did not conduct up to 80° C.; from this temperature to 210° C, its conductivity gradually increased, after which the conductivity again diminished; in cooling it followed the same law, but in a different ratio. The modification prepared by heating to 100° C. only is Dr. Werner Siemens' 1st, or electrolyte modification, whilst the other, prepared by heating to 210° C., is his 2nd, or metallic modification. In the 1st, the conductivity *increases* with rise of temperature; in the 2nd it *decreases*; the 2nd is a much better conductor, but is less stable, and its conductivity increases with the intensity of the light, as shown from the following table, in which is given the effects of different intensities of light on selenium (Modification II.) obtained by Dr. Obach in Mr. Siemens' laboratory at Woolwich on the 14th February, 1876:—

Selenium in	Relative conductivities.		Resistance in Ohms.
	Deflections.	Ratio.	
1. Dark	32	1·	10,070,000
2. Diffused daylight ...	110	3·4	2,930,000
3. Lamplight...	180	5·6	1,790,000
4. Sunlight	470	14·7	680,000

From these experimental results an extension of Helmholtz's theory is derived, viz., that the conductivity of metals varies inversely as their total heat (Helmholtz having only the sensible heat in view), and the influence of light upon selenium is explained by a change in its molecular condition near the surface, from the first or electrolyte into the second or metallic modification, or, in other words, by a liberation of specific heat upon the illuminated surface of the crystalline selenium.

In testing the sensitive selenium plate in the different parts of the spectrum, it was shown that the actinic ray exercised no sensible effect, that the effect increases as we gradually approach the dark red, and that beyond that point the effect again decreases, reaching almost zero in the heat rays; the value of the material then for purposes of photometry is apparent.

Dr. Werner Siemens has constructed a selenium photometer, in which the selenium is prepared so as not to be affected by the changes to which that substance is liable, and which consists of a single sensitive plate mounted upon a vertical axis, upon which it can be turned through a certain angular distance limited by stops. When touching the one stop the selenium stands opposite the normal candle, and when touching the other opposite the light to be measured, the distance upon the former being changed upon a scale until no effect upon the needle of a galvanometer is produced in turning the sensitive plate in rapid succession from the one stop to the other.

The lecture was concluded by the exhibition of a selenium eye, which Mr. Siemens had prepared to illustrate the extraordinary sensitiveness of the selenium preparations. It consists of a hollow ball with two circular openings opposite each other, the one being furnished with a lens 1½ inches in diameter, and the other with an adjustable stopper carrying a sensitive plate, which is connected by wires to a galvanometer and one Daniell's cell. The lens is covered by two slides representing eyelids, the ball itself being the body of the eye, and the sensitive plate occupying the place of the retina. Having placed a white illuminated screen in front of the artificial eye, on opening the eyelids a strong deflection of the galvanometer was observed, a black screen giving hardly any deflection, a blue one a greater, a red a much greater, but still short of that produced by the reflected white light. The eye was thus sensitive to light and colour, and as stated, it would not be difficult to arrange a contact and electro-magnet in connection with the galvanometer, so that intense light would cause the automatic closing of the eyelids. The artificial eye is subject to fatigue, and the lecturer considered that this experiment might be suggestive to physiologists as regards the natural conjoint action of the retina and the brain.

THE LATE COLONEL STRANGE, F.R.S.

LIEUT.-COL. ALEXANDER STRANGE, F.R.S, whose death we last week announced, was the fourth son of the late Sir Thomas Strange, and was born at Westminster on the 27th of April, 1818, and was educated at Harrow. On leaving school in 1834, at the early age of sixteen, he proceeded to India, and joined the 7th Regiment of Madras Light Cavalry, where his natural talents began to develop themselves. He shortly afterwards made the friendship of General Worster, who soon discovered that he had mechanical abilities of the highest order, and who subsequently instructed him in the use of astronomical and surveying instruments, and pointed out to him that nature had intended him for a scientific career. During the next few years he became a devoted student at the Magnetic and Meteorological Observatory at Simla, then under the direction of Major-General Boileau, R.E., at whose recommendation he was nominated, in 1847, by Col. (now Sir Andrew) Waugh, R.E., Surveyor-General of India, to the office of Second Assistant in the Great Trigonometrical Survey, where he found work suited to his talents. He was originally selected on account of his ability as an observer, and for his extraordinary mechanical skill, which in this department was of special value, and was displayed in such a remarkable degree as to call forth the highest commendation from Col. Waugh. In the season 1848-49 he was attached to the party under Capt. (now Col.) Renny Tailyour, R.E., in order that he might acquire a practical knowledge of geodetical operations. Such was the rapidity with which he made himself master of this difficult subject, that in 1850 he was promoted to the grade of First Assistant. Capt. Tailyour was ordered to undertake the triangulation of what is known as the "Karáchi Longitudinal Series," which constitutes the southern flank of that considerable portion of the principal triangulation of the Survey of India known as the North-west Quadrilateral. It commences at Sironj in Central India, and terminates at Karáchi, in Sind. The extent of this arc of longitude is equivalent to 670 miles in length, covers an area of 23,000 square miles, and is one of the largest longitudinal arcs ever measured on the surface of the globe. At the end of the first season, Capt. Tailyour's services being required at head-quarters, Capt. Strange was ordered to take over the entire charge of the Series, and it is on this great undertaking that his fame as an Indian Surveyor rests. After crossing the Desert, over which the triangulation had to be carried nearly 200 miles, the work was carried on with the highest skill across the Plains of Sind, until at length, after much anxiety, and having overcome almost insuperable difficulties, the last angle which completed this great triangulation was measured on April 22, 1853, and the work brought to a successful close.

The remarkable energy and rapidity with which this series was carried on, under many and great difficulties, was reported by the Surveyor-General to reflect on him the highest credit. He was directed to join the Surveyor-General's camp near Attock, where he took part in the verificatory base line. After this he returned to Karáchi with the base-line apparatus, and took a leading share in the measurement of the base-line at that place in the year following. Meantime he had been distinguished with the title of "Astronomical Assistant." In 1855 Strange joined the Surveyor-General's Head Quarters' Office, and in the following year was placed in charge of the triangulation which was being extended from Calcutta southwards towards Madras, along the eastern coast. In April, 1857, whilst conducting the triangulation in the Goomsoor Hills, a notoriously unhealthy tract, he was struck down by jungle fever, and was afterwards ordered to the Neilgherry Hills for the recovery of his health. In the year 1859 he was promoted to the rank of major, and in accordance with the then existing regulations of the service retired from the Survey, on which occasion he received the special thanks of the Government of India.

In January, 1861, he returned to England after twenty-six years' continuous service in India, and finally retired from the army as lieutenant-colonel on the 31st of December, 1861. His career in England was no less brilliant than that in India. In 1861 he was elected a Fellow of the Royal Geographical Society as well as a Fellow of the Royal Astronomical Society. He served on the Council of the latter from 1863 to 1867, and was Foreign Secretary from 1868 to 1873. On the 2nd of June, 1864, he was elected a Fellow of the Royal Society, of which he soon became a distinguished member; he served on the Council from 1867 to 1869.

In the year 1862 the Secretary of State for India in Council sanctioned the provision of an extensive equipment of geodetical and astronomical instruments of the first order, for the service of the Great Trigonometrical Survey of India, consisting of one great theodolite, two zenith sectors, two 5-feet transit instruments, two electro chronographs, two diagonal transit instruments, two 12-inch vertical circles, and three astronomical clocks. The task of designing and superintending their construction was entrusted to Lieut.-Col. Strange, who was also appointed to the post of Inspector of Scientific Instruments to the Indian Government. To enable him to test these valuable instruments as well as the current supply required by the Public Works, Survey, Meteorological, and various other Departments in India, an Observatory was established at the India Store Depôt in Lambeth from designs prepared by himself. This observatory, in its various ingenious details, is a monument of Col. Strange's consummate mechanical genius.

At this Observatory, theodolites, levelling instruments, prismatic compasses, sextants, telescopes, barometers,

thermometers, drawing, and mathematical instruments of all kinds were rigorously inspected, compared, and verified under Col. Strange's personal superintendence, and the improved forms of instruments now supplied to the services in India, are in a very large measure due to his efforts, and it must have been a source of gratification to him to find that they were received with almost universal approbation. He devoted much anxious time and thought to the laborious task of testing the magnificent series of instruments above alluded to.

The telescope has an aperture of $3\frac{1}{4}$ inches, with a focal length of 36 inches. The instrument is constructed upon what is known as "the flying micrometer plan," and possesses a great number of peculiarities which are quite unique. It will be found fully described in a paper read by him before the Royal Society in 1872. This is undoubtedly the finest instrument of its kind ever constructed, and will be an enduring monument to his unremitting energy and constructive genius. The zenith sectors were designed for the accurate determination of latitude, and in design are unlike any of their predecessors; being intended for portable instruments the problem was to get the maximum of power out of the minimum of weight, and in this he was eminently successful, for on comparing one of these with the weight of the zenith sector designed by the present Astronomer Royal for the Ordnance Survey of Great Britain it was found to be only about one-half. With regard to the performance of these instruments, Capt. J. Herschel, R.E., F.R.S., who has been employed in determining latitudes in Southern India, in comparing the facility of working the zenith sector and the former astronomical circles of the Great Trigonometrical Survey, states that "the sectors are competent to turn out at least double the amount of work of the same order," adding, "at this rate two or three years' work, would equal in amount the whole results up to the date of the arrival of the sectors, and ten years (a comparatively short period for which to arrange a system of observation on a matter of this magnitude) will see us in a position to look back on the arrival of the sectors as on the commencement of a new era." All the other instruments present evidences of Col. Strange's constructive genius.

Such is the amount of skill and forethought brought to bear upon the design of these exquisite instruments that an observer may select a series of stars differing only five minutes of time in Right Ascension. Each star is observed twice in reversed positions of the telescope at the same culmination, and each of the two reversed observations involves two settings of the telescope in altitude, four microscope, two level and one micrometer reading. To admit of all these operations being performed within five minutes of time, with the deliberation requisite for observations aiming at fractions of a second, demands the highest conveniences of instrumental construction.

After their completion and final testing, they were severally despatched to India, where they have for some years been employed in the Survey Department, unapproachable for manipulative facilities and giving results unsurpassed in accuracy. Indeed, it is not too much to say that these instruments, in the construction of which Col. Strange had the advantage of being so ably seconded by the late Mr. Cooke, of York, and the well-known firm of Troughton and Simms, are the most perfect and powerful geodetical instruments which have ever been constructed or are likely to be constructed for some years to come.

Among his publications which appear in the Memoirs of the Royal Astronomical Society, vol. xxxi., are the following: "On Testing the Vertical Axes of Altazimuth Instruments," "On a Direct Method of Testing and Adjusting the Equipoise of Altazimuth Instruments," "On a Proposed Isolated Flange for Conical Axes." In the Monthly Notices of the Royal Astronomical Society, vol. xxiii.: "On Aluminium Bronze as a Material for the Construction of Astronomical and other Philosophical Instruments;" and in the Journal of the Royal United Service Institution, vol. vi., "Geodesy, especially relating to the Great Trigonometrical Survey of India." He contributed papers on various subjects to the Royal Society, the British Association, the Society of Arts, the Meteorological and other scientific and learned societies.

His scientific activity, however, was by no means confined to these questions, which came before him in his official capacity. In compliance with a request made by her Majesty's Commissioners for the International Exhibition of 1862, Col. Strange served the office of juror. He also performed the same functions at Paris in 1867. "While in the Royal Society," to quote from the memoir in the *Times*, "he insisted upon the accuracy of the measurements used in physical inquiries, in the British Association, and was the clear-sighted and constant advocate of increased instruction in science and the increased utilisation of it in our public departments; and he was among the first to insist upon the national importance of fostering the pursuit of knowledge in those fields which, though unremunerative to the cultivator, are eventually of the highest importance to the nation. To him belongs the whole credit of having initiated in 1868 the movement which resulted in the appointment by her Majesty of the 'Royal Commission on Scientific Instruction and the Advancement of Science,' of which his Grace the Duke of Devonshire was chairman, and the five years' labours of which have but recently terminated. Before he died he had the satisfaction of knowing that the proposals contained in the scheme which he originally propounded to the Commission, and on which nearly the whole of the witnesses were examined, were adopted in the main by the Commission, and recommended for the consideration of the Government. Thus the breadth of his views, and the clearsightedness which he possessed not only combined to render his services to the Indian Government and to the various scientific societies, Councils, and Committees on which he served of the utmost value, but they have left a memorial in the recommendations of this Commission, some day, we hope, to be rendered more lasting by their adoption. He died on the 9th inst. at the comparatively early age of fifty-seven, and the void his death has created in the scientific world will be one very difficult to fill."

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA[1]

V.

ORDER *Sirenia*. The purely aquatic habits and fish-like form of the animals of this order formerly caused them to be confounded with the Cetacea, but a more intimate knowledge of their structure has shown that they really belong to a widely different type of the class. Their skeleton is remarkable for the massiveness and density of most of the bones of which it is composed, especially the skull and ribs, and the bodies of their vertebræ want the disc-like epiphyses so well marked in the Cetacea. The existing members of the order pass their whole life in the water, being denizens of shallow bays, estuaries, and large rivers, but unlike the Cetacea they are never found in the high seas away from shore. Their food consists entirely of aquatic plants, either marine algæ or fresh-water grasses, on which they browse under water, as the terrestrial Ungulates do on the green pastures on land. They are generally gregarious, slow and inoffensive, and apparently stupid in disposition. Though occasionally found stranded

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.) Continued from p. 388.

by the tide or waves, there is no evidence of their voluntarily leaving the water to bask or feed on the shore.

The species now existing are very few, and there is reason to believe that the time is not far distant when they will all become extinct. One species, the *Rytina stelleri*, or Northern Sea-cow, an animal attaining nearly the length of thirty feet, by far the largest known member of the order, from the North Pacific, was totally exterminated by the agency of man during the last century, and the surviving species, the Manatis and Dugongs, being valuable for their flesh as food, their hides, and especially for the oil obtained from the thick layer of fat which lies immediately beneath their skin, rapidly diminish in numbers as civilised populations occupy the regions which form their natural habitat.

The Manatis (genus *Manatus*), found on the Atlantic coasts of America and Africa, are rather fluviatile than marine in their habitat, ascending large rivers almost to their sources, and feeding chiefly on aquatic grasses. The Dugongs (genus *Halicore*) are more distinctly marine, feeding chiefly on algæ. They inhabit the shallow waters, bays and creeks of various coasts of the Indian Ocean, the Red Sea, East Coast of Africa, the Indo-Malayan Archipelago, and north coast of Australia. There is probably not more than one species, but they have been divided into three according to the locality which they inhabit. *H. tabernaculi* from the Red Sea, *H. dugong* from the Indian Seas, and *H. australis* from Australia. These two existing genera present such well-marked distinguishing characters that if they alone were known they might be placed in separate families, but as in so many similar cases our knowledge of the extinct forms, imperfect as it is, goes far to bridge over the distinction between them. It is true that Brandt, a great authority on this group, divides the order into two primary sections—*Manatidæ*, consisting of *Manatus* alone, and *Halicoridæ*, containing all the other genera; but it scarcely seems that these can be considered in any sense as equivalent, especially as one of the distinguishing chracters, the external form of the tail is unknown in the extinct genera.

The Miocene and early Pliocene seas of Europe abounded in Sirenians, to which the generic name *Halitherium*, Kaup, has been given. They had large tusk-like incisors in the upper jaw, as in the existing *Halicore*, though not so greatly developed. Their molar teeth are $\frac{5}{5}$ or $\frac{6}{6}$, anteriorly simple and single-rooted, posteriorly with three roots in the upper jaw, and two below, and with enamelled, tuberculated, or ridged crowns, in which respect they approach nearer to *Manatus*, the molar teeth of the Dugongs being without enamel and single-rooted. The anterior molars were deciduous. Some species, at least had nasal bones, short, broad, but normal in position, whereas in all the existing genera these bones are quite rudimentary. Another and still more important evidence of conformity to the general mammalian type is the better development of the pelvic bone, and the presence of a small styliform femur articulated to the acetabulum, although no traces of any other part of the limb have been discovered. These ancient Sirenians were thus, in dental, cranial, and other osteological characters, less specialised than are either of the existing species, and if the intermediate links could be discovered, might well be looked upon as ancestral forms from which the latter have been derived, but at present the transitional conditions have not been detected. As far as we know, when changes in the physical conditions in the European seas rendered them unfitted to be the habitation of Sirenians, the Halitherium type still prevailed. If the existing Dugongs and Manatis are descended from them, their evolution must have taken place during the Pliocene and Pleistocene epochs, the one in seas to the east, the other to the west of the African continent, which has formed a barrier to their intercommunication. Halitherium remains have been found in many parts of Germany, especially near Darmstadt, in France, Italy, Belgium, Malta, the Isthmus of Suez, &c. Until lately none were known in our own country, probably owing to the absence of the beds of an age corresponding to those in which they are found on the Continent; but quite recently a skull and several teeth have been detected among the rolled *débris* of Miocene formations, out of which the Red Crag of Suffolk is partially composed. The species are not yet satisfactorily characterised. Some of them appear to have attained a larger size than the existing Manati or Dugong. One of these from the Pliocene of Italy and France, having but $\frac{5}{5}$ molar teeth, has been separated generically under the name of *Felsinotherium* by Capellini, by whom it has been fully described. A portion of a skull found in Belgium has been named *Crassitherium*, by Van Beneden, and some compressed teeth, somewhat similar to, but larger than those of the Dugong, discovered in the department of Lot et Garonne, France, have given origin to the genus *Rytiodus* of E. Lartet. *Pachyacanthus* of Brandt, from the Vienna basin, is also, according to Van Beneden, another form of Sirenian, of which, however, the skull is not known. In various Miocene and perhaps Eocene marine formations of the United States of America, remains of Sirenians have been discovered, but mostly in such a fragmentary condition that they afford at present little evidence of the early history of the group in that country. A more satisfactory discovery is that of a nearly complete skull and some bones from a limestone tertiary formation in Jamaica. It is of smaller size than the Manati, and as far as the teeth are concerned, of a still more generalised character than Halitherium, the dentition being apparently

$$i\,\frac{3}{3}\,c\,\frac{1}{1}\,p\,\frac{5}{5}\,m\,\frac{3}{3} = 48.$$

The incisors are small, not developed into tusks, the canines (wanting in all existing Sirenians) are rather longer than the incisors, judging by the sockets, and the molars are bilophodent, and covered with enamel. It has been described by Prof. Owen under the name of *Prorastomus sirenoides*. Unfortunately we have no knowledge of the geological antiquity of the formation in which it was embedded. Lastly must be mentioned the *Eotherium ægyptiacum*, Owen, founded on the cast of a brain, with a small quantity of surrounding bone, discovered in the Nummulitic limestone of Eocene age of the Mokattam Hills, near Cairo. The brain is narrower than that of *Manatus*, and resembles *Halitherium*. This is of interest, as the most ancient known evidence of any Sirenian, whose age has been geologically determined.

The few facts we have as yet been able to collect of the former history of the Sirenians leave us as much in the dark as to the origin and affinities of this peculiar group of animals as we were when we only knew the living members. They lend no countenance to their association with Cetacea, and, on the other hand, their supposed affinity with the Ungulata, so much favoured by modern zoologists, receives no very material support. The assumption lately put forth with so much confidence that the Sirenia are the remains of a group of animals, through which the Cetacea passed in their evolution from terrestrial Mammalia, is quite without foundation.

(*To be continued.*)

PROF. HUXLEY'S LECTURES ON THE EVIDENCE AS TO THE ORIGIN OF EXISTING VERTEBRATE ANIMALS[1]

II.

IT was seen in the last lecture that no ultimate answer was obtainable as to the origin of the examples selected from the fish class, any more than is afforded as

[1] A course of six lectures to working men, delivered in the theatre of the Royal School of Mines. Lecture II., March 6. Continued from p. 389.

to the origin of the Anglo-Saxons by showing that they came from Friesland in the sixth or seventh century. The same remark applies to the origin of nearly all fishes, in fact, only one clear case of progressive modification is known in the whole class; this is afforded by the group of the *Pycnodonta.*

These are fish not unlike our John Dory in shape, which appear for the first time in the carboniferous rocks, and become extinct in the older tertiaries; they are distinguished by the possession of rows of large crushing teeth, and in place of a vertebral column had a gelatinous *chorda dorsalis* or *notochord.* The spinal cord above this was embraced by arches of bone, placed at regular intervals along the chorda; and, immediately below these neural arches, were attached the ribs, also bony. In the Carboniferous forms, both arches and ribs are quite distinct from one another, and are simply united by ligamentous fibres to the notochord; but, in the older Secondary species, they become expanded at their ends, and thus tend to embrace the notochord; and, lastly, in the Tertiary pycnodonts this process is carried to such an extent as almost to produce a ring of bone, like the body of a rudimentary vertebra.

Now let us turn to the next group of Vertebrate animals, that of Amphibia (frogs, toads, newts, and salamanders), which are distinguished from fishes by certain very striking peculiarities. Fishes are all capable of breathing the air dissolved in water by means of gills, and—a far more important distinctive character—their limbs always have the character of *fins*, which organs are seen in their simplest form in Ceratodus. In this fish, there is a long jointed cartilaginous axis, running down the middle of the fin, with rows of rays of the same substance on each side of it; the whole is invested by a fold of the integument, the margins of which are beset with horny filaments called fin-rays. In all fishes these elements are to be found, generally in a curiously modified condition; in the bony fishes, for instance, the central axis with its side appendages are broadened out and shortened, the fin-rays becoming at the same time so much larger as to form the main part of the fin.

Some modification of this type of limb is possessed by all fishes which have limbs at all; but the first character, that afforded by the respiratory organs, is not absolute, for there are some fishes which, besides gills, possess an apparatus for breathing air directly. This apparatus, represented by the air-bladder of ordinary fishes, first takes on its new character and becomes a lung in that remarkable genus, Ceratodus, in which it exists as a large cellular structure situated in the upper part of the abdominal cavity, just under the vertebral column, and connected with the gullet by a slit—the glottis—by means of which the fish can pass air from the mouth into the lung. It is not, however, this peculiarity of opening into the œsophagus which constitutes a lung, for the air-bladder of many fishes possesses an open duct of a similar nature; the great distinguishing feature is, that the blood taken to this bladder does not pass into the ordinary venous channels, but is returned immediately to the heart, in a purified condition, by a special vein. In Ceratodus there is no special vessel to carry blood *to* the lung, in other words, although there is a pulmonary *vein*, the pulmonary *artery* has not appeared; but in the Mudfish (Lepidosiren) of Africa and eastern South America, the development of the lung goes a step further, a special pulmonary artery being present, as in all the higher animals. Thus Ceratodus and Lepidosiren are truly *amphibious*, for they can be suffocated neither by removal from water like most fish, nor by immersion in water like the higher animals.

What constitutes the difference between these amphibious fish, and the lowest of the true Amphibia? Not the nature of the respiratory process, for many of the latter group, such as the blind Proteus of the Austrian caves and the North American Menobranchus possess gills throughout life, but the structure of the limbs, which are now, no longer *fins*, but *legs*. A fish requires a broad surface for balancing itself in the water, locomotion being chiefly performed by the tail, but in land animals an apparatus is required capable of raising the body above the ground, and the limbs take on the form of a set of jointed levers. In its simplest form the higher vertebrate limb consists, first, of a single piece of cartilage articulated with the body, then two pieces side by side, then a number of small nodules, and lastly, five series of short jointed pieces; all of these become in the adult state more or less converted into bone. The first or proximal division of the limb is called the humerus in the fore limb, the femur in the hind limb; the next segment consists of radius and ulna in the arm, tibia and fibula in the leg; the nodular pieces are respectively carpals and tarsals, and the series of jointed bones or cartilages, the five digits. From the lowest Amphibia upwards, the limbs, when present, are always constructed upon this type.

Nevertheless, the Amphibia still retain certain fish-like characters, which are lost in the groups above them. They all, at some period of life, breathe by means of gills, although all have, in the adult state, lungs in addition. Some forms, such as the Proteus and Menobranchus mentioned above, retain their gills throughout life and are hence called *Perennibranchiates;* others, such as Menopoma, Amphiuma, &c., lose them in adult life, and are called *Caducibranchiates.* These two last genera, however, still retain traces of gill-clefts, but in all the Amphibia with which we are acquainted in this country, the frog, toad, and newt, even the clefts disappear, and the perfect air-breathing character is assumed.

These animals, in the course of their development, go through a very singular series of metamorphoses, comparable to those by which a grub is converted into a butterfly. At this season of the year, every pond is almost certain to contain frog-spawn, masses of transparent albuminous matter, with numberless imbedded eggs, consisting of yolk, black on one side and white on the other. A few hours after these eggs are laid, the process of development begins by the formation of a shallow groove, which appears quickly on the black, more slowly on the white hemisphere, and is just such a groove as would be produced by drawing a blunt instrument along the equator of a soft globe. The egg is thus divided into two masses. A second form appears at right angles to the first, dividing the whole egg into four; others appear, in definite order, cutting it up into smaller and smaller masses, until the whole yolk becomes granular, or formed of microscopic *cells*. Two ridges then appear, on the surface of the egg, and, uniting in the middle line, inclose a cavity, the lining membrane of which is converted into the brain and spinal cord. The head gradually becomes differentiated, and the mouth appears on its under side; the tail grows out, and the little creature, getting too long for the egg, becomes coiled upon itself, and, before long, ruptures the egg-membrane, and makes its exit from its mass of jelly.

It is now, to all intents and purposes, a fish; it has no limbs, its mouth is provided with horny jaws, and it breathes by means of a pair of plumose gills. It further differs from the adult frog in being herbivorous, feeding on water plants, to which it attaches itself by means of two suckers near the mouth. The tadpole grows rapidly, and, before long, a fold of skin appears on each side, which gradually closes over the gills, leaving, however, for a considerable time, a small opening on the left side. In the meantime the limbs appear, and the lungs are developed, the tadpole breathing for a time both by lungs and gills; the latter eventually disappear, the tail shortens, the limbs lengthen, the horny jaws are replaced by teeth, and an insect-eating tail-less frog is formed, the adult air-breathing form having thus been attained by a wonderful

series of changes, in which the fish, Lepidosiren, perennibranchiate, and triton, are all represented.

One would be inclined to infer from these metamorphoses, that, on tracing the Amphibia back in time, the story of their origin should be told, but, as a matter of fact, palæontological history tells a different story altogether. Abundant remains of frogs and toads are found in the Miocene deposits, some of which are of so fine a character that even the tadpoles are preserved; but these tertiary frogs and toads do not differ, in any important particulars, from those of the present day, and the same is true of the tritons and salamanders. Some of the latter attained a very great size, and one of them—a near ally of the great Japanese salamander of the present day—has had a very singular fate, having been described, about the middle of the last century, as a fossil man, by the German naturalist Scheuchzer, who named it "Homo diluvii testis," the man who saw the flood!

In the Wealden and Purbeck formations no Amphibia have as yet been discovered, but, from the Lower Lias to the Carboniferous they turn up again in remarkable numbers, and of great size, but differing from existing forms in some important peculiarities, and affording no help whatever to our inquiries as to the origin of the existing or of the tertiary frogs, toads, and salamanders. Under the throat, these gigantic Amphibia had a remarkable shield of three bony plates, as well as a series of plates along the belly. Their teeth were large and powerful, and presented an extremely complicated structure, whence the group has received its name of *Labyrinthodonta*.

Thus, in tracing back the existing Amphibia, we find a great break in the secondary period, and then come upon a distinct group, the Labyrinthodonta, from which the existing forms cannot possibly be deduced. These, again, have been traced no farther back than the carboniferous epoch.

(*To be continued.*)

PHYSICAL SCIENCE IN SCHOOLS

THE beginning of a discussion on any great subject elicits mainly differences of opinion; its end should be to establish agreement as to principles, and in great measure as to details. The first half of this dictum has been illustrated by the interesting letters in your columns on Physical Science in Schools; its entire confirmation as the correspondence proceeds will confer on education a benefit of the most timely kind.

The moment is a critical one for scientific teaching. Lord Salisbury's Bill will come to mean a revolution in the educational structure of the Universities; the Report of the Science Commission proposes to re-cast the teaching of the schools; public feeling, unexpressed as yet on other points, is distinct in wishing to see Science heartily recognised and systematically taught. If Science Teachers will agree as to what they want and press it vigorously, the game is in their hands.

I venture to lay down for consideration in NATURE certain propositions on this subject in the hope that they, or such others as may be preferred to them, may become the basis of the agreement we all desiderate:—

1. The business of a school is general education; the business of a University is special education.

2. The principal subjects taught at a school should be Literature, Mathematics, Science.

3. Each of these subjects should be studied in fixed relative proportions of time, from the very beginning of a school course until its close.

4. Scholarships offered for any one of these subjects to the exclusion of the others at the entrance on University life are mischievous in their effect on school teaching, and ought to change their character or be abolished.

5. Science should be taught to every boy in a school for at least six hours in the week; holding a fair place in Entrance Examinations, being encumbered with no pecuniary charges unimposed on other subjects, and having a value in school-marks proportional to the time spent upon it.

Of these five theses, the first three and the fifth are in exact harmony with the recommendations of the Science Commission; the fourth follows necessarily from the others, as stigmatising a system whose continuance makes general-school teaching impossible, and whose significance gains point from the curious admission of one of your correspondents as to the intellectual cost of a Balliol Scholarship.

The feasibility of teaching science to the youngest schoolboys, assumed in what I have said, demands a word of comment. The evidence on this point scattered through the Report of the Commission, and partly summarised in Report VI., pp. 6—9, is, if not overwhelming, so strong as to outweigh many-fold anything that has yet been said against it. I desire to advance with humility, but with great earnestness, my own experience, extending over fourteen years, in support of the view there laid down; and Mr. West's admirable letter in NATURE, vol. xiii., p. 48, represents, as I well know, the conclusions of many successful teachers. If grammatical analysis and arithmetical numeration are taught every day to boys of nine years old, why not the elements of science? It were well surely to inquire what parts of this vast subject and what treatment of them have been found suitable to younger minds; for the statement on the part of any individual that science cannot be taught to little boys means nothing more than that he himself has failed to teach it.

My object in writing is a practical one. I have stated the principles which seem to me to underlie all school science teaching worthy of the name, and I invoke a judgment upon them, possibly a reversal of them, at the hands of experienced teachers. If it be true, as we were lately told, that the head-masters are awaiting instruction from the public, let us prepare the public to educate their illustrious pupils. At any rate, let scientific men be ready to answer the appeal which will be made to them when the Report of the Science Commission comes before the House of Commons, with such unanimity as only abundant and unprejudiced discussion can generate. To let slip this opportunity will be to find, I fear, with the Jew of Malta, that "Occasion 's bald behind."

W. TUCKWELL

I notice in your columns that a discussion has been conducted for some time past on that important subject, Physical Science in School Teaching. Permit me, as one possessing a deep practical interest in this matter, and also as a science teacher of some years' experience, to remark that in Scotland, generally, and in this great educational centre in particular, the chief obstacle which stands in the way of extended science teaching, is the simple apathy of educationalists to the claims of scientific instruction. It were well that, before disagreeing as to the exact mode of teaching, the claims of one science over another, and other points, science teachers should thoroughly agree as to the necessity for more openly enforcing their claims upon the notice of those who sit in high places in the world of educational management. I gladly welcomed an opportunity afforded me by the Edinburgh branch of the "Educational Institute of Scotland," in December last, to address the members of the Institute, consisting in the main of teachers of all subjects, on the "Place, Method, and Advantages of Biological Instruction in Ordinary Education." The substance of that address will shortly appear in *Fraser's Magazine*, and to that medium I would respectfully refer those of your readers who are interested in this question, for a *résumé* of a science teacher's work and method in the northern metropolis. I would fain hope that the argu-

ments therein stated, as applying to the extension of my especial subject—Biology—may be found to suit the case and claims of science teaching at large. And it may not be inappropriate to conclude by re-echoing the remark with which I started, namely, that if we can succeed in creating a *demand* for science teaching, by showing the honest claims and true value of scientific instruction in an ordinary educational curriculum, we shall have paved the way for a harmonious and natural after-adjustment of such questions as have very ably been ventilated in NATURE during the past few weeks.

Edinburgh Medical School ANDREW WILSON

I have read with considerable interest what may be styled the evidence of your correspondents as to the state of scientific instruction in schools, and I think possibly if your space will permit me, that I shall be able to confirm some of the statements of previous writers. I have reason to believe that in some large schools where science is demanded as a branch of education it is practically suppressed, some of the clever lads are removed from the science classes in order to be "crammed" in classics, sometimes against their own desires, for the purpose, if possible, of making a show in school-lists as having obtained scholarships at Oxford. I am acquainted with facts which cannot be otherwise explained. Sometimes I have learned these from the boys themselves, sometimes from science-masters in different establishments. At one large school in connection with a College there are about 600 boys; formerly very nearly 100 attended chemistry lectures once a week, and about 25 attended the chemical laboratory of the College for 1½ hour. The subject was a voluntary one, and the undoubted interest shown by the scholars was very striking; one could see that they were being taught to think, it was something so entirely different from their ordinary school work. For the last year or two the number of boys attending these science classes has been limited almost entirely to those who intend matriculating at the London University, those whose parents expressly wish their sons to receive such education, or others "the most stupid and ignorant," who are so unlikely to hold their own in any other competition that it is considered they may be better fit for distinction in science. I need hardly say that one fails to make anything of the latter class, although, on the other hand, I have seen such lads display unusual mechanical skill. The number of boys from the school now attending the laboratory is only eight, and those who hear lectures about thirty-six. In a school with unusual facilities for scientific instruction at a small cost, since the teachers, the laboratories, the lecture-rooms, and the very costly scientific apparatus, all belong to the College, there is this small result simply because the pupils are prohibited attending the lectures on science lest, as it is said, "*they should shirk their other work.*" This is certainly not equalising the various branches of human knowledge. In some schools the science masters are appointed not from among those who have made the teaching of science a study, but from that peculiar body who are willing to combine instruction in science (which includes, of course, Physics, Chemistry, Natural History, and Botany), with Mathematics, Classics, and Foreign Languages, and whose views as to the suitable remuneration for their services suggests a limited expenditure of thought, time, and money, on their own acquirements. From the present low estimation in which scientific knowledge is held, I should be exceedingly sorry to see the number of efficient science teachers increased. The capital expended on a classical education gives a far better, a more certain, and a quicker return than that invested in science. Hence the lamentations about the state of science in this country. Until the Head Masters and College dons have been so liberally educated as to understand that besides Classics and Mathematics there are other branches of knowledge which ennoble and enrich the understanding, and further, until a legal status has been secured for professional scientific men, such things must continue. W. N. HARTLEY

NOTES

THE John Hopkins University, some account of the organisation of which we recently published, was formally instituted at Baltimore, U.S., on February 22. Prof. Gilman in his address hinted that elementary instruction in all branches of science is not contemplated at the new University. There will be no stated curriculum of four years. Great freedom is to be allowed both to teachers and to scholars; the former must be "free and competent to make original researches in the library and the laboratory;" the latter will be encouraged to "make special attainments on the foundation of a broad and liberal culture," and to make them through a "combination of lectures, recitations, laboratory practice, field work, and private instruction." Pending the filling of the several professorial chairs, the trustees will ask the most eminent men, both in Europe and America, to come to Baltimore during a term of years, and reside there an appointed time, "and be accessible, *publice et privatim*, both in the lecture-room and in the study." One most important appointment has already been made, by which England will lose, for a time at least, one of her most distinguished mathematicians; Dr. J. S. Sylvester has been appointed to the Chair of Advanced Mathematics, at a handsome salary. Prof. Sylvester will probably enter upon his duties in October next.

THERE is great activity at present at South Kensington; the preparations for the opening of the Scientific Loan Exhibition are in a forward state. A large number of contributions have been already received from France, Germany, Belgium, Holland, and Italy.

CONTRARY to the assertion of a contemporary, who apparently desires to mislead, the men of science of this country are giving the greatest help in the organisation of the Conferences and Conversazioni in connection with the Loan Exhibition; these will be held between May 16 and 31.

H.M.S. *Challenger* arrived at Monte Video on Feb. 15, and was to sail on Feb. 23 for Ascension and St. Vincent. The ship is expected to arrive in England about the end of May.

A CAREFULLY prepared and well classified and indexed Catalogue of Maps, &c., of India, and other parts of Asia, has been prepared by the Geographical Department of the India Office, and published by order of H. M. Secretary of State for India in Council. The Catalogue is accompanied with an Index-Map showing the different sheets which are published or which are being prepared by the engraver for publication.

M. J. CAPELLO, director of the Observatory at Lisbon, has selected Lisbon, Campo-Maior, Angra in the Azores, and Funchal in Madeira, as the stations from which meteorological observations will be furnished for international objects. Their situation, and the fact of their observations being made four times daily, have determined the selection of these four stations. The hours are well suited for purposes of international meteorology.

THE Belgian Academy of Sciences offers prizes for papers on the following subjects, to be sent to the Secretary, M. J. Liagre, at the Museum, Brussels, before Aug. 1, 1877:—1. To give a *résumé* of works which have appeared on the theory of continued fractions, and to improve it in some important point. 2. To examine and discuss, on the basis of new experiments, the perturbing causes which bear on determination of the electro-motive force, and on the internal resistance of an element of the electric pile; to exhibit in numbers these two quantities for some of the

principal piles. 3. New researches to establish the composition and mutual relations of albumenoid substances. 4. To establish, by direct observations and experiments, the functions of the various anatomical elements of Dicotyledinus stems, especially in relation to the circulation of nutritive substances and the use of the fibres of the liber. 5. Does the generative vesicle perform the same part in eggs which are developed without previous fecundation (by parthenogeneses) as in fecundated eggs? 6. Investigation of the cycle of evolution in a group of the class of Algæ. —The conditions usual in such competitions are laid down, and the prizes are gold medals varying in value from 600 to 1,000 francs.

THE *Athenæum* of Saturday last has a well-timed and justly severe note in connection with the filling up of two vacancies among the trustees of the British Museum. A writer in the *Times* has mentioned the names of Sir Henry Rawlinson and Mr. Layard as having claims for the vacant posts, and the *Athenæum* shows that only one trustee is appointed by the Crown, and that the two vacancies will be filled up by the Trustees themselves. "Let us hope," the *Athenæum* says, "that they may see fit to appoint the two scholars in question, or at least one of them. But if they are elected, they will succeed to a perfectly barren honour, unless they are subsequently placed on the Working Committees. It is notorious, that Dr. Hooker, who is a trustee, by virtue of his office as President of the Royal Society, has absolutely no voice in the disposal of the vast collections of natural history contained in the Museum; and that, although there is no naturalist among the trustees with the exception of Sir Philip Egerton. And it is doubtful whether such men as Mr. Layard and Sir Henry Rawlinson, whose sympathies are likely to be with progress and reform, with scholarship and education, will be quite in harmony with that system which has made the British Museum what it now is. They might not feel anxious to strengthen the hands of those officials who are said to have recently endeared themselves to the gentlemen and scholars beneath them by the issue of a slave circular (to use the name by which it is popularly known in the Reading-room), of which it is asserted that some member of the legislature will before long demand the publication."

WE are grateful to the *Daily News* for the advanced and decided views it always takes in matters affecting the interests of science; indeed its advocacy of the claims of science in the country is a distinctive feature of the paper. In an able article in Friday's issue the unsatisfactory condition of the British Museum is pointed out, and it is shown that until an entirely new system of management is instituted, no reform can be expected. "It would seem, indeed, as if the framer of the constitution of the British Museum had, with fiendish malignity, selected precisely those persons as trustees who could by no possibility find time to attend to their duties." It is shown that the recommendations of successive Royal Commissions have been ignored, and that no means have yet been taken to carry out improvements which would greatly increase the usefulness of the Museum. We hope that this article, in conjunction with the note in the *Athenæum* to which we have referred, will have some effect in stimulating the Government to carry out the recommendations of the Duke of Devonshire's Commission and take steps to render the Museum of greater service than it is to science and the country; and that even with its present drawbacks it does render great services must be admitted.

THE Royal Irish Academy has made the following grants out of the fund placed at its disposal by Parliament for advancing scientific research:—35*l*. to Rev. Eugene O'Meara for further Report as to the Distribution of Irish Diatomaceæ; 12*l*. to Prof. Leith Adams for a Report on Irish Pleistocene Mammals; 50*l*. to Rev. Prof. Haughton for a Report on the Tidal Constants of the Irish Coasts (towards the sum of 100*l*. required for the expenses to be incurred); 25*l*. to Dr. Studdert and Mr. Plunkett for a Report on the Nature of the Mineral Waters of Mallow; 20*l*. to Dr. Chichester Bell for Report on the Chemical Constitution of Pyrol; 40*l*. 12*s*. 8*d*. to Dr. Emerson Reynolds for Report on the Atomic Weight of Glucinum; and 10*l*. to Dr. E. P. Wright for Report on Chytridia Parasitic on Florideæ.

THE Royal Irish Academy, at its stated meeting held on the eve of St. Patrick's Day, elected the following honorary members:—In the department of Science: Carl W. Borchardt, Alphonse Decandolle and Ernst Haeckel. In the departments of Polite Literature and Antiquities: Thomas Carlyle, Margaret Stokes, William Stubbs, Eugène E. Viollet-le-duc, and Ernst Windisch.

M. EMILE DE GIRARDIN and others are trying to organise a Universal Exhibition in Paris for 1878.

THE electric lamp and gramme machine which have been used so successfully at the Northern Railway Station, Paris, have been sent *viâ* Marseilles to Malta, to be employed in the illuminations when the Prince of Wales stops there on his way home from India.

IN the title to Mr. Evans's recent address to the Geological Society, we inadvertently prefixed Royal to the designation of the Society; we regret that so important a society has not attained to this dignity.

THE Imperial Zoological-Botanical Society of Vienna, celebrates, on April 8, its sixtieth anniversary.

ON July 1 an Exhibition of Arts, Manufactures, Agriculture, &c., will be opened at Helsingfors, the capital of Finland.

PROBABLY not many of our readers are aware of the fact that Great Britain has recently become possessed of the island of Socotra, near the mouth of the Gulf of Aden. Mr. P. L. Sclater calls attention to the fact in Saturday's *Times*, in order to intimate that we are almost completely ignorant of its natural productions. We trust, with him, that the new British Governor and his assistants will not neglect to furnish us, before long, with some account of the natural denizens of this *terra incognita*.

FEARS are entertained that the extraordinary dryness which has recently prevailed in Algeria will lead to a famine. It is stated that no rain has fallen this summer during the usual wet season.

IT is said that a number of governments have given their approbation to the scheme initiated by Austria for sending to the Polar regions a number of vessels to explore scientifically the countries which have been discovered by the *Polaris* and *Tegethoff* expedition.

VISCOUNT CARDWELL is to ask the Government to-day in the House of Lords what course they intend to pursue with regard to Cambridge University. In answer to the Marquis of Lansdowne who, on Monday, among other things asked whether Science would be represented in the Oxford University Commission as well as rank, dignity, and learning, the Marquis of Salisbury stated he had no objection to name the Commissioners next Monday, and at the same time he would state the nature of the amendments to be proposed by the Government.

VAST masses of dense smoke were reported to be issuing from Mount Vesuvius on Sunday; flame was visible at night; the apparatus at the Observatory was in a state of disturbance, and an eruption seems probable before long.

DR. PETERMANN has sent us one of the best maps we have seen illustrating Cameron's route between Lake Tanganyika and the coast. The map, which is based on that of the Royal Geographical Society, is on a comparatively large scale, shows the

routes of Cameron, Livingstone, Magyar, and the Pombeiros, Cameron's camping stations, all the rivers observed by Cameron, and is coloured to show the orographical features. It extends from 3° to 13° N. lat.

IN Monday's *Times* is a long letter from the Rev. S. Macfarlane, giving an account of an interesting trip in the missionary steamer *Ellangowan*, for 170 miles up the Fly River, New Guinea. The account seems to be essentially the same as that read at the last meeting of the Geographical Society. Signor D'Albertis was on board and obtained a considerable number of natural history specimens. Mr. Macfarlane sums up the results of the trip as follows:—"Several important ends have been gained by our visit to the Fly River. We have proved that there really is a navigable river there extending far into the interior of the country. We have opened up the way, which has hitherto been guarded with great determination by savages, and have taught them the danger of attacking European vessels. On our return we succeeded in establishing what appeared to be a genuine friendship between the natives and ourselves, exchanging presents. We have learnt something of the character of the interior; and, although we found it low and swampy up to the highest point we reached, we have at least proved that high land is not to be reached within at least two hundred miles by the course of the river, the first hundred being thickly populated by a mixed race—Papuan and Malayan—speaking different dialects, and at war with each other. They are an intelligent-looking, energetic people. We obtained a considerable number of specimens of natural history. We were disappointed at not reaching high land with populous and healthy villages suitable for stations."

THE death is announced of the widow of the late Hugh Miller at the age of sixty-four years. She took a chief part in editing her husband's works after his death, and gave much assistance to Mr. Peter Bayne in the preparation of the sturdy geologist's biography.

DR. PARKES, F.R.S., the distinguished professor of hygiene at the Army Medical Schools, died on the 15th inst.

THE Oxford Burdett-Coutts Scholarship has been awarded to Mr. A. H. S. Lucas, of Balliol College.

SEVERAL letters have appeared in the *Daily News* calling attention to the fact that on Sunday week red snow was observed to have fallen in several parts of the country—at Forest Hill and Streatham in the south of London, at Reading and at Thurston in Norfolk. This phenomenon was observed in ancient times, and is referred to by Pliny; in modern times it has been frequently observed in all parts of the world, and is familiar to Arctic explorers. The phenomenon is generally ascribed to the presence of an algæ, *Protococcus nivalis*.

WE have received from the U.S. Geological and Geographical Survey of the Territories one of these valuable publications, which it is grievous to think the caprice of a political party may soon bring to a stop. This is a preliminary map of South-west Colorado, and part of Utah, Arizona, and New Mexico, showing the location of ancient ruins. The map is on the scale of five miles to an inch, and shows not only the sites of the prehistoric ruins which abound in the region, but the courses of the principal rivers and of dry gulches, and by means of lettering the general character of the surface of the country.

Bulletin No. 1, vol. ii. of the Geological and Geographical Survey of the Territories, under the direction of Prof. Hayden, is one of unusual interest. It contains seven articles, with the following titles:—1. A notice of the ancient remains of South-western Colorado examined during the summer of 1875. 2. A notice of the ancient ruins in Arizona and Utah lying about the Rio San Juan. 3. The human remains found near the ancient ruins of South-western Colorado and New Mexico. 4. Ancient art in North-western Colorado. 5. Bead ornaments employed by the ancient tribes of Utah and Arizona. 6. Language and utensils of the Utes. 7. Fossil Coleoptera from the Rocky Mountain Tertiaries. The text is illustrated with twenty-nine octavo plates, embracing cliff and cave houses, arrow-heads, pottery, human skulls, &c. Mr. Scudder's article contains descriptions of thirty-one new species of fossil Coleoptera.

THE first section of the building for the American Museum of Natural History, in Central Park, New York, will be ready for occupation in the coming summer. Some time ago, our readers may remember, New York appropriated 700,000 dollars to commence this edifice, and it has also set aside for this section and its future extensions, 18¼ acres of land worth from 5,000,000 dollars to 8,000,000 dollars. The whole edifice when complete will be about eighteen times as large as that now nearly ready, and will cost about 15,000,000 dollars. The collection is at present in a wooden building, which is visited by an average of 13,600 people per week—2,000 more than the average weekly number of visitors to the entire collections in the British Museum.

THE additions to the Zoological Society's Gardens during the past week include two Suricates (*Suricata zenik*) from S. Africa, presented by Mr. G. Thorburn; a Knot (*Tringa canutus*), European, presented by Mr. C. Clifton; a Rhesus Monkey (*Macacus erythræus*) from India, presented by Mr. Robert Law Ogilby; a Bonnet Monkey (*Macacus radiatus*) from India, presented by Mr. J. Shortland; a White-Cheeked Capuchin (*Cebus lunatus*) from Brazil, presented by Dr. Lynn; an Aztec Conure (*Conurus aztec*) from Mexico: two All Green Parrakeets (*Brotogerys tiriacula*) from S. America, purchased; a Collared Fruit Bat (*Cynonycteris collaris*), born in the Gardens.

REPORT OF THE CAMBRIDGE STUDIES' SYNDICATE

THE Syndicate appointed in May last year to consider the requirements of the University of Cambridge in different departments of study, have just issued their Report. This contains many features of interest. We reprint the answers of the Board of Natural Science Studies to the questions sent by the Syndicate. What the nature of these questions is may easily be gathered from the answers.

I.—A—(*a*). The Board is of opinion that lectures are required in the University on the following subjects:—1. Principles of chemistry and inorganic chemistry, organic chemistry, physical and thermal chemistry, &c., analysis, elementary qualitative, analysis, elementary quantitative, analysis (1) of minerals (metallurgy, &c.); (2) organic; (3) volumetric; (4) spectrum.

Catechetical lectures are also required, suited for students of different degrees of attainment. There should be also laboratory teaching in practical chemistry, including qualitative and quantitative analysis and instruction in chemical research. Probably one term would suffice for each course of lectures, except the general course on chemistry and perhaps the course on organic chemistry which might occupy two terms each. For the special courses on analysis one or two lectures a week or three lectures a week for part of a term would suffice.

2. An elementary course on physics, occupying two terms. Special courses:—(1) General physics, dynamics, &c. (1 term). (2) Heat and thermodynamics (2 terms). (3) Sound and Light (2 terms). (4) Electricity and Magnetism (3 terms). (5) Methods of observation, &c. (1 term). Higher courses (chiefly mathematical):—(1) Heat and thermodynamics (1 term). (2) Sound and light (1 term). (3) Electricity and magnetism (2 terms). There should be a course of practical laboratory instruction extending over three terms, and special laboratory teaching for advanced students.

3. A course on elementary crystallography, and one on mineralogy, together occupying about two terms.

4. General geology, physical geography, and geological physics. Stratigraphical geology. Petrology. Palæontology—general.

Special Palæontological lectures and demonstrations in connection with the lectures on stratigraphical geology.

5. *Elementary biology.

6. Systematic botany:—(1) *Elementary and (2) Advanced.

7. Vegetable morphology and physiology:—(1) *Elementary, and (2) Advanced.

8. Zoology:—General. Special, (1) Vertebrates. (2) Molluscs. (3) Insects. (4) other Invertebrates.

9. Comparative anatomy:—(1) Elementary and (2) Advanced. *Embryology. Osteology.

10. Physiology:—(1) Elementary and (2) Advanced. *Physiology of the senses. *Physiology of nutrition.

11. Human anatomy, including animal mechanics, &c.:—(1) Elementary and (2) Advanced. *Ethnology.

Each of the courses on the subjects numbered 5 to 11 would probably require two terms, except those marked *, each of which might be concluded in one term. In many of these subjects more or less catechetical teaching would be desirable.

With respect to the distribution of these courses among different teachers:—

1. The general superintendence of the chemical laboratory with the delivery of one course of lectures, usually those on general chemistry, would sufficiently occupy the time of the professor. Organic chemistry, including the superintendence of the practical work in this subject, would occupy the greater part of the time of a second professor. He might, however, in some cases also deliver one of the special courses. Some of the special departments of chemistry might perhaps be undertaken by demonstrators, but for the remainder, and for catechetical instruction with a proper division of classes, two additional teachers are at present needed who may very well be inter-collegiate lecturers.

2. The superintendence of the physical laboratory, with the teaching of such branches of mathematical physics as are not provided for by other professors under the jurisdiction of the Mathematical Board, would probably occupy all the time of the Professor of Experimental Physics. The special experimental courses might, if necessary, be given by demonstrators, but at least one regular teacher of experimental physics in addition to the professor would be desirable.

3. The mineralogical teaching at present required in the University might be given by the professor, the students being referred for the chemical part of the subject to one of the teachers of Chemistry.

4. Stratigraphical geology, petrology, and Palæontology would each require a separate teacher. Lectures on different portions of stratigraphical geology might be delivered in different years. Parts of the course on general geology (*e.g.* that on glacial phenomena, earth movements, &c.) might be given by the lecturer on stratigraphical geology. Some parts (*e.g.* that on volcanic phenomena) being undertaken by the petrologist. Special demonstrations on Palæontology in connection with the course on stratigraphical geology might be given by curators or demonstrators.

5. The course on elementary biology might be given by a demonstrator acting under a Professor of Physiology or of Comparative Anatomy.

6. The elementary and advanced courses on systematic botany might be given by one teacher.

7. The elementary and advanced courses on vegetable morphology and physiology might be given by one teacher. A third botanical teacher (for cryptogamic botany) will probably be required at a future time.

8. The general course of zoology requires one teacher. The teaching which is at present required in the special departments of zoology might be given by Curators of the Museum, who should also act as demonstrators; but special teachers of each of the four departments will be required eventually.

9. The elementary and advanced courses on comparative anatomy might be undertaken by one teacher. The courses on embryology and osteology might be given by demonstrators; but each subject is important enough to occupy the whole time of a teacher if a suitable one is available.

10. The elementary and advanced courses on physiology require one teacher. The remarks made on embryology and osteology apply also to the subjects of the physiology of the senses and the physiology of nutrition.

11. Elementary and advanced courses on human anatomy might be undertaken by one teacher. The subject of ethnology would be best undertaken by a separate teacher if circumstances should admit.

A (*b*). It is desirable that the University should have the opportunity of inviting men who have devoted themselves successfully to the prosecution of special departments of science to give lectures in the University; but the delivery of such lectures must depend rather upon the men being forthcoming than upon any *à priori* consideration of what subjects require elucidation.

B (*a*). Viewing this question with reference simply to the numbers of students, there appear to be no branches of natural science in which the classes which require to be put through exactly the same course in the same term are so large as to require division.

B (*b*). The approximate number of students in the University classes in most of the above great groups of subjects is from twenty to thirty; in the class of elementary biology the number is larger; in chemistry the number is nearly a hundred. The number may be expected to increase.

C. In most of the natural science subjects opportunities for individual personal intercourse between teachers and students occur in the course of laboratory and field work. Most of the professors encourage the students to ask questions after lecture, and some give short catechetical lectures before the ordinary lecture.

D. For the superintendence, under the professors, of the laboratory work, and for giving instruction in such of the special chemical subjects as may not be otherwise provided for, four demonstrators are required. If the number of students increases, more demonstrators will be required. In physics not less than three demonstrators will probably be required. Each of the professors or other principal teachers of chemistry and physics will require a lecture assistant, and boys to do general work in connection with the laboratories will be required in the proportion of about one to each demonstrator. In the geological Museum three curators or demonstrators will be required—one of these at a time would be occupied as a demonstrator in assisting the professor and the Palæontologist—the others would be engaged in the general work of the Museum. The petrologist would require a curator who should also act as demonstrator. The Professor of Geology also requires an assistant to prepare and keep in order diagrams, maps, models, &c. The teacher of systematic botany requires a demonstrator. The teachers of vegetable morphology, of comparative anatomy, and of physiology will each require demonstrators in the proportion of one to every ten or fifteen students. Assistance in the same proportion will be required for the class in elementary biology, but this may probably be provided from the staff of the teachers of comparative anatomy, physiology, and vegetable morphology. Four curators, who might also act as demonstrators, will be required for the special departments of zoology. One or two demonstrators in human anatomy will be required.

E. In addition to special libraries attached to the different departments, a general scientific library, easily accessible from the Museums is required. In *Chemistry*. A new and more spacious laboratory is urgently required. To this should be attached a museum of chemical preparations. In *Geology*. A new museum has long been an acknowledged want. In *Botany*. Workrooms are required in connection with the Herbarium; also a laboratory for vegetable morphology and physiology, including rooms for microscopical work, &c. In *Zoology*. Workrooms are required for the professor, superintendent of the museum, curators, and demonstrators. In *Comparative Anatomy*. A laboratory is required, including dissecting-rooms, rooms for microscopical work, &c. In *Physiology*. A laboratory is required, including chemical laboratories, rooms for microscopical work, &c. In *Human Anatomy*. Dissecting-rooms are required, and rooms for microscopical work. Each department will require rooms for research, microscopes and other apparatus, as well as diagrams.

Such are the requirements necessary to make instruction in natural science fairly complete. In the physical departments the wants of chemistry are the most urgent; teachers of palæontology and petrology are urgently required. In reference to more immediate wants of the biological departments, it may be stated that the present teaching staff consists of the Professors of Anatomy, Botany, and Zoology and Comparative Anatomy, each of whom, except the Professor of Botany, has a demonstrator.

The chief teaching of physiology is at present conducted by the Trinity Prælector in Physiology. The additions to the teaching staff most urgently required are (1) a professor or teacher of comparative anatomy; (2) a more definitely recognised teacher of vegetable morphology and physiology; (3) two

curators in zoology (molluscs and insects), to act also as demonstrators; (4) two Demonstrators of Physiology; (5) an additional Demonstrator of Comparative Anatomy; (6) an Assistant-Curator of the Herbarium, to act also as Demonstrator of Systematic Botany; the Professor of Botany being *ex officio* Curator of the Herbarium. The appliances most urgently needed are laboratories for chemistry, comparative anatomy, physiology, and vegetable morphology, and workrooms for the zoological museums.

II. (*a*) It is desirable that all the teachers in each of the several departments should be grouped in one organisation.

(*b*) The Board considers that while there is room in the University both for professors and lecturers, appointed directly by the University, and for inter-collegiate lecturers, it is undesirable to have lecturers in natural sciences teaching members of their own colleges exclusively.

(*c*) It appears that physiology, comparative anatomy (as distinguished from zoology), and vegetable morphology and physiology (as distinguished from systematic botany), are so important and so distinct that they should be entrusted to independent professors, but till this can be done the subjects may be undertaken by other lecturers.

(*d*) It seems desirable that the selection of University professors should be entrusted to a body of about seven electors, of whom a majority should be residents in the University; that such electors should be appointed either for life, for a term of years, or by virtue of holding some official post, and that those who are not *ex-officio* electors should be nominated by the Board of Studies with which the professorship is connected, and be elected by the Senate. Further, that the selection of other teachers appointed by the University, but not directly subordinate to the professors, should be made by similar bodies of electors resident in the University, or by the several Boards of Studies, and that demonstrators should be appointed as at present.

(*e*) It seems desirable that in the case of the recognition of individual inter-collegiate lecturers by the University, the appointment of such lecturer should receive the confirmation of the several Boards of Studies.

III. (*a*) It seems highly desirable that the professorial and inter-collegiate lectures should be brought into closer relations with each other; and it seems probable that this may be effected, in part at least, by organising meetings of the professors and other teachers in each department, in order to arrange a plan of combined action in teaching, and to consider and determine a scheme of lectures, such scheme to be submitted to the Board, and, if approved by the Board, published at the beginning of the academical year by its authority.

Further, the Board thinks it desirable that the university should appoint, from time to time, on the recommendation of the Boards of Studies, lecturers on any subject or subjects which may not at the time be adequately represented by professors, inter-collegiate lecturers, or other teachers.

(*b*) The Board is not prepared to suggest any further provision for the organisation of the professorial lectures in its department.

With respect to inter-collegiate lectures, the control exercised by the Board over the authoritative publication of the scheme drawn up after consultation with the professors would, it is hoped, be sufficient for the effective organisation of the whole system.

(*c*) The power given to the Board of Studies of remitting for further consideration any scheme of professors' lectures which the Board disapproves, may be used to prevent any undue interference of one professor with the departments properly belonging to another.

With regard to competition in a wider sense, the Board does not see that any regulation of it is necessary or desirable.

Considering the importance in many cases of the lectures on natural sciences being delivered in a central building, and of the University collections being made as much use of as possible, it is desirable that power should be possessed by the Museums and Lecture-rooms Syndicate, or by some other University authority, to allow inter-collegiate or other lecturers, recognised by the University, to make use of University lecture-rooms, museums, &c., with the consent of the professors concerned, and under such conditions as may be found necessary to avoid interference with the work of the professors or risk of injury to the collections.

IV. There seem to be two ways in which the advancement of knowledge may be assisted by organisation. One is by giving mature students (in which light the Board must regard the professors and inter-collegiate lecturers) some amount of leisure for the prosecution of their studies, and some inducement to pursue them with energy, and to give the results of them to the world. The other is by giving opportunity to younger students, such as our younger graduates, who may show promise of capacity to do original work, and who are anxious to attempt it, the opportunity of making their first essays, under skilled guidance and under favourable conditions, in some place where their qualifications can be judged and their results appreciated.

A considerable part of the original work done by those engaged in the higher teaching at Cambridge must probably be always done during the vacations, but it must be always difficult for a professor, or other advanced teacher, to keep himself well acquainted with all that is being done in his department, to say nothing of advancing knowledge in it, unless the more engrossing kind of work is so distributed and arranged that each of the principal teachers should have one term in the year of, at any rate, comparative leisure. For any additional stimulus that may be necessary in order that such leisure may be employed for the benefit of science we must look to public opinion.

In order to encourage and facilitate the advancement of knowledge by the younger graduates, it seems desirable that most of the rather numerous demonstratorships which are required should be temporary appointments, and should be offered to such of the younger graduates and others as shall have shown a desire to attempt original work, and given promise of capacity for doing it. The work of the demonstrators, however, if it is properly done, takes up so much time and energy that but little original work can be expected from them, unless they too are allowed, at any rate, comparative freedom from work for one term in the year, during which they may be expected to assist the professors in their researches, or to carry on work of their own under the direction of the professors. They should not be allowed to take private pupils. In all branches of natural science it is desirable that the teaching should be continued throughout the terms and not be limited as at present to the middle two-thirds.

SCIENTIFIC SERIALS

American Journal of Science and Arts, February.—The first article is an obituary notice of Sir W. E. Logan, read before the Natural History Society of Montreal last October.—Mr. W. B. Taylor contributes a continuation of his history of recent researches in sound.—Mr. A. H. Rowland continues his studies on magnetic distribution, in which he critically examines M. Jamin's recent work.—On the rifts of ice in the rocks near the summit of Mount McClellan, Colorado, and on the different limits of vegetation on adjoining summits in the territory, by Edward L. Berthond. Mount McClellan is 13,430 feet high, and contains mines which are extensively worked. At a height of 13,100 feet, and about 30 feet from the entrance of the tunnel of one of the mines, were three or four veins of solid ice, parallel with the bedding of the rock, and filling all its inner side with cracks and fissures. In another tunnel 300 feet westward and about 100 feet from the entrance, veins of ice were also met with. It has been suggested that this ice has remained ever since the Glacial period. The mountain presents these two strange antagonistic phenomena in immediate proximity. On one side of the valley there is a mountain slope facing north-east, well grassed, totally devoid of shrubs and trees, where the rocky *débris* are underlain by a perpetual icy coat hundreds of feet in depth, supporting on its surface a growth of plants strictly Alpine and Arctic, and abounding with Ptarmigan, *Lagopus leucurus*, and the tail-less, earless marmot. A list of plants found bloom Oct. 2, 1875, is given. Less than half a mile distant on the opposite slope of the vale *Pinus aristata* of large size and a profuse growth of birches, willows, grasses, and arbutus abound.—On a new form of lantern galvanometer, by Francis E. Nipher, which possesses the advantages of being adaptable to any vertical lantern; the distance between the deflecting coils is readily varied and can be adjusted to currents of various intensity; the resistance of the galvanometer is quickly varied from one half to twice the resistance of the galvanometer coils.—On the occurrence of tartronic acid, with some remarks on the molecular structure of glyceric acid, by S. P. Sadtler. A comparison is made of two views taken of glyceric acid, and it is suggested that there are two isomeric acids, one of which is normal and the other an unsymmetrical acid.—On the "chloritic formation" on the western

border of the New Haven region, by J. D. Dana.—A new Tertiary lake basin, by G. B. Grinnell and E. S. Dana. During recent explorations a new series of Tertiary deposits has been found at Camp Baker, Montana; they indicate the existence in this region of a Miocene lake basin, which was succeeded by another lake basin in Pliocene time.—The remaining papers are: The product of the action of potassium on ethyl succinate, by Ira Remsen.—The action of ozone on carbon monoxide, by the same.—The appendix contains an article on the Dinocerata, by O. C. Marsh, with five plates.

Journal de Physique, Dec. 1875.—We simply name the principal papers in this number, which are mostly of a mathematical nature:—Application of the laws of Coulomb to electrolytes, by M. G. Lippmann.—On the determination of condensing power, by M. Terquem.—On the magnetisation of steel by currents, and on the situation of the poles in long needles, by M. Bouty.—On an experiment relative to the transformation of forces (we refer to this more fully elsewhere).—Criticising a paper of Mr. Tomlinson's on the action of solids in liberating gas from solution, M. Gernez disputes that observer's result in the experiment in which a small metallic cage with very close meshes is introduced into seltzer water. M. Gernez says that, varying the experiment in many ways, he has always found that the gaseous mass imprisoned in the cage increases at expense of the dissolved gas. In a few minutes it increases sufficiently for bubbles to be formed in the larger meshes, and one may even determine beforehand the points where gaseous liberation will take place, by enlarging certain meshes with the point of a needle.

SOCIETIES AND ACADEMIES

London

Royal Society, Feb. 17.—"On Experimental Contributions to the Theory of Electrolysis," by Alfred Tribe, Lecturer on Chemistry in Dulwich College. Communicated by J. H. Gladstone, Ph.D., Fullerian Professor of Chemistry in the Royal Institution.

Linnean Society, March 2.—Prof. G. J. Allman, president, in the chair.—Sir Victor A. Brooke, Bart., Mr. R. B. Croft, Dr. Ralph Gooding, Mr. F. J. Horniman, and Mr. W. Percy Sladen were elected Fellows of the Society.—Preceding the business-routine, it was the painful duty of the President to announce the demise of John J. Bennett, F.R.S., who formerly, and for twenty years most creditably acted as secretary to the Linnean Society. Among his scientific labours the "Plantæ Javanicæ" worked out a then imperfectly-trodden field; his colleague in the said volume being Robt. Brown, *facile princeps botanicorum*. Mr. Bennett afterwards, and for years, was chief of the botanical department of the British Museum, retiring to Sussex, where he died. As a man he worked well, wisely, and energetically, and his name will always be remembered among botanists and friends as ripe in science, humanity, and fulness of heart. Another Foreign Member who has lately died, M. Adolphe T. Brongniart was among the most distinguished botanists of our age and a Fellow of the Society for upwards of forty years. His fame will rest on his "Végétaux Fossiles," wherein he may be said to have laid the foundation of fossil botany. He, moreover, wrote a vast number of other original and independent memoirs, and still found time for years to conduct as editor the botanical section of the *Annales des Science*, enriching the same with his great erudition.—J. Gwyn Jeffreys, F.R.S., exhibited on behalf of Sir James Anderson, a fine and interesting specimen of the so-called felt or blanket sponge, *Askonema setubalense*, Kent. This was picked up Aug. 24, 1875, along with the telegraph cable from a depth of 550 fathoms off Cape Finisterre.—Mr. C. Stewart called attention to peculiarities of the large rossette spicules found in its fluffy structure.—A mould of the upper surface of the cranium of the fossil *Ornithocheirus* and various fragments of the skeleton were exhibited and commented on by Prof. Seeley; these illustrating points raised in a former paper of his "On the Organisation of the Ornithosauria."—A paper was read on a new genus of Turneraceæ from Rodriguez, by I. B. Balfour, F.L.S. The tree in question is known to the inhabitants under the name of *Bois Gaudine*, and grows on the hilly parts of the island. It possesses a fine-grained, light-coloured wood, which, however, is not much used. The tree itself is handsome though small, being very erect in habit; its terminal branches are clothed with a light-green foliage. This new genus *Mathurina*, has close relationship to *Erblichia*, but differs manifestly from *Turnera* and *Wormskioldia*, its circumscribed habitat, moreover, lending additional interest. Mr. J. G. Baker, of Kew, in addition, stated that the botanical results of this Rodriguez Transit of Venus Expedition, through Mr. Balfour's collecting, had yielded some 280 species of flowering plants and ferns. Of these 110 were common weeds and 170 species indigenous to the island. The botany of Rodriguez, with a total area of fifteen miles, has now been fully settled by Mr. Balfour's researches, and these go to sustain its flora as belonging to the temperate region, and not truly tropical in character.—A paper on pollen was communicated by M. P. Edgeworth, F.L.S. The pollen grains of some 400 species have been carefully examined and drawn to scale by the author, those of the main orders of plants receiving comparison. It results from his survey that some families appear to have the bodies in question of variable forms, while others are remarkably uniform in shape.—Notes on algæ found at Kerguelen Land (by the Rev. A. E. Eaton), by Prof. Dickie, F.L.S. In this paper three new species, *Sphacelaria corymbosa*, *Melobesia kerguelini*, and *Ptilota eatoni* are described. The total number of algæ recorded are 65; of these 16 belong to the Olive, 34 to the Red, and 15 to the Green series. While there are 9 peculiar to the island, 21, or about one-third, are also found on European shores.—A list of the Musci and Hepaticæ collected in Kerguelen Island (by the Rev. A. E. Eaton), by William Mitten, F.L.S., was taken as read. This contains reference to 38 mosses and 13 liverworts, of the former, *Bartramia eatoni*, of the latter, *Tylimanthus viridis* and *Balantiopsis incrassata*, are new to science.—W. Carruthers, F.R.S., in calling attention to the specimens on the table, gave a *résumé* of the recent researches of Prof. De Bary of Strasbourg, into the potato fungus. The Peronosporeæ De Bary separates into three genera. In *Cystopus* the conidiophores grow in large bunches, the conidia, or bud-cells, being developed in single rows in basipetal order. In *Peronospora*, from a tree like mycelium, conidiophores arise singly or in small bunches at the end of the branches, and have no successors in the direct line. *Phytophthora* differs from the last in its multiple and successive conidia, which, when shed, leave swellings on the branches. The ripe conidia in all, when placed in water, produce zoospores, or nucleate moveable cells provided with cilia. These penetrate the plants, and, ceasing to move, develope threads, or mycelium. By another sexual method of propagation the oogonia, bladder-shaped female cells, after being fertilised by the small male cells, antheridia, produce from their protoplasm a thick-walled oospore. Mycelial threads sprout from this latter and the above process is repeated. A considerable period of inactivity may, however, precede the germination of the oospore, which in this case hybernates for the winter, whilst its host decays. The conidia, De Bary states, propagate and spread the fungus during the summer season only, but do not live through the winter. He has, moreover, found in decayed potato tubers bodies exactly corresponding to oospores. On experimenting with the oogonia of these and planting them in potatoes he obtained bodies which conducted themselves precisely like zoospores, and in most respects resembled those of *Pythium*. Other experiments with them, on the moistened legs of dead flies and bodies of mites, resulted in their complete phases of development, which was watched step by step, the zoospores producing a plentiful crop of mycelium, &c. As this new fungus in many ways differs from the *Phytophthora infestans*, he names it *Pythium vexans*, on account of his trouble therewith. He regards it as a true Saprolegniea. De Bary has likewise investigated the question of the perennial mycelium of *Phytophthora* occasionally discharging the function of hybernation where the oospores are not found in the district. He believes he has established by proofs that there are two methods whereby the conidia pass from the tuber to the foliage. The general opinions held in this country De Bary is at variance with. Mr. Worthington Smith replied at some length to Mr. Carruthers' epitome, and criticised De Bary's conclusions unsparingly. Dr. Masters supported Mr. Smith's views, as opposed to Prof. De Bary's interpretation of the subject at issue. Further discussion of this interesting topic was postponed till next meeting. A series of the said parasitic fungi prepared by De Bary were exhibited under the microscope to the Fellows present. His complete memoir hereafter is to appear in the Roy. Agric. Soc. Trans.

Chemical Society, March 16.—Prof. Abel, F.R.S., president, in the chair.—Before commencing the ordinary formal

business of the Society, Dr. J. H. Gladstone rose and in a short speech proposed a vote of thanks to the president for the exceedingly enjoyable visit to the Royal Arsenal at Woolwich on the preceding Tuesday, and for his generous hospitality on that occasion. This was seconded by Dr. Gilbert and carried by acclamation. The following papers were then read:—On crystallosed glycerin, by Dr. P. F. van Hamel Ross; notes on the fatty acids and on a suggested application of photography, by Mr. W. H. Hatcher.—On stibine, by Mr. F. Jones.—On the use of platinum in the ultimate analysis of carbon compounds, by Mr. F. Kopfer; —and on the action of organic acids and their anhydrides on the natural alkaloids, Part v., by Mr. G. H. Beckett and Dr. C. N. A. Wright.

Royal Astronomical Society, March 10.—Mr. Huggins, president, in the chair.—Since the last meeting the Society has received a valuable present of rare books from the library of the late Mr. Sheepshanks. Lord Lindsay has also presented the Society with the sun-spot manuscripts and observations of the late Mr. Carrington, a very valuable series, which has been made use of in determining the present received values of the elements of the position of the sun's axis and the drifts of the solar photosphere.—A paper by Dr. Royston Piggott was read on a star-illuminated transit eye-piece. A sheet of glass, on which a thin film of silver is deposited, is placed in the focus of the eye-lens; transparent lines are drawn on the film, instead of wires, and as the star passes across the lines it is seen to flash out brightly. The film of silver is made sufficiently thin to permit of the star being seen when it is between the lines, but it appears that the lines themselves are only visible, except in the case of very large stars, when the star disc is in transit across a line. Capt. Abney read a paper on photographing the least-refracted end of the solar spectrum. He said that within the last two years many attempts had been made to photograph the ultra-red rays. Dr. Vogel, in 1874, and more recently Capt. Waterhouse, had made use of aniline dyes in the collodion. They stated that with a red dye the collodion was found to be most sensitive to the red end of the spectrum. He had repeated these experiments, and had obtained only partial success; he had, however, from considering the chemistry of the question rather than the physical explanation which had been given and which he believed to be a mistake, been led to try other experiments as to mixing gum resins with the collodion, and had obtained a compound which was very sensitive to the long wave-lengths, so that he had been able to obtain distinct traces of the spectrum beyond A. He hoped to continue his experiments and to give a fuller account of them to the Society at a later meeting.—Two papers were read on the proper motion of the star B. A. C. 793. It appeared from the remarks of the Astronomer Royal and Mr. Dunkin that there is no sufficient evidence to prove that its proper motion has changed during the present century.—Capt. Noble drew attention to a paper by M. Normand on the occultation of stars by the planets as a means of determining the solar parallax. He wished the owners of large telescopes to determine with what degree of accuracy they could observe the occultation of minute stars at the limb of Mars.

Entomological Society, March 1.—Prof. Westwood, president, in the chair.—Dr. G. Kraatz, President of the German Entomological Society, Berlin, and Mr. Clemens Müller, of Berlin, were elected Foreign Members; and Mr. O. E. Jansen was elected an Ordinary Member.—Mr. Jenner Weir exhibited two grasshoppers, in an undeveloped state, taken by himself in the Rhone valley, *in copulâ*—a peculiarity which had frequently been observed among the Hemiptera. He also exhibited a remarkable moth from Madagascar belonging to the *Uraniidæ*, bearing a very striking resemblance to a *Papilio*, except that it had the antennæ of a moth, and the hind wings were destitute of tails.—Mr. E. Y. Western exhibited Coleoptera taken chiefly in Switzerland.—Mr. W. Arnold Lewis exhibited a specimen of *Argynnis Dia* taken in England by Mr. Wallace A. Smith. Mr. Smith, who was present at the meeting, stated in answer to various inquiries by the President, that he had taken the specimen in 1872 in Worcester Park, and distinctly remembered the capture, as it was the first fritillary he had ever had in his possession, and also that it had never been out of his possession since.—Mr. Bates read a paper from Mr. Trovey Blackmore to Mr. McLachlan stating that he was much interested in observing a notice in the Proceedings of the Society respecting the habits of *Cychrus cylindricollis*, reported by M. Baudi to feed on snails. He had already called attention (in the *Entomologist's Monthly Magazine*, vol. xi. p. 214) to the fact that the *Carabus stenocephalus*, Fairm., fed on snails, which in Morocco were so very abundant as to form a marked feature in the landscape by covering the bushes so thickly as to resemble, at a distance, clusters of blossom. He had captured in all eighteen specimens of this rare *Carabus*, and of these fifteen were obtained either feeding on snails or climbing up bushes of *Retama*, which were covered with snails, especially with *Helix planata*. The *Carabus* having an unusually long head, and the prothorax being narrowed anteriorly enabled it to thrust its head and prothorax a considerable distance into the shell in search of its food. Mr. Blackmore referred to some other North African species of *Carabi*, which he thought might be found to have similar habits to those of *C. stenocephalus*.—The President read a paper entitled "A Dipterological Note from Pompeii," containing remarks on the habits of the genus *Bombylius*. The President also presented descriptions of some new species of *Tipulidæ* in the British Museum, accompanied by drawings, showing them to be furnished with hind legs of unusual length.—Mr. John Scott contributed a monograph of the British species belonging to the *Hemiptera-Homoptera* (family *Psyllidæ*), together with a description of a genus which might be expected to occur in Britain.

Physical Society, March 11.—The president, Prof. G. C. Foster, F.R.S., in the chair.—The following candidates were elected members of the society:—W. H. Coffin, T. D. Humpidge, and Rev. G. H. Hopkins.—Prof. W. G. Adams gave an account of some researches on which he has been engaged in connection with the influence of light and heat on the electric conductivity of selenium, and exhibited numerous experiments in illustration. The subject has also been studied by Lieut. Sale and Dr. W. Siemens of Berlin, and as a general result it is found that after it has been kept in the dark, the resistance of the metal is diminished by exposure to light. The effect, however, both of heat and light, is different in the several states through which the metal passes. Thus when a piece of amorphous selenium is gradually heated to about 100° C. kept at this temperature and slowly cooled, its resistance at first is so great that it cannot be measured by the ordinary arrangement, but as its temperature increases, the resistance diminishes and increases again more slowly when the metal is allowed to cool. The resistance of several pieces which at the higher temperature were from one to three megohms were found to be from 100 to 130 at the ordinary temperature. If this selenium be placed in a paraffin bath and heated, its resistance diminishes, and when the temperature is kept constant above 140° C. for some hours and the metal is then slowly cooled, it assumes a crystalline structure, and its resistance *diminishes* as it cools. The resistance of such selenium at ordinary temperatures *increases* with the temperature. The effect is more marked as the temperature of the paraffin bath is increased. In studying the effect of light, the metal which had been heated to 140° C. was exposed to a candle at distances of 1, $\frac{1}{2}$, and $\frac{1}{4}$ metre; the initial resistance being 115,500 ohms. The readings in these three cases were 112,000, 108,700, and 101,500. Deducting each from the initial number we have 3,500, 6,800, and 4,000 ohms as the changes of resistance due to exposure at these distances. Hence the effect of light varies inversely as the distance or, what amounts to the same thing, directly as the square root of the illuminating power. These considerations have led Prof. Adams to suggest the use of selenium for comparing the illuminating powers of different sources of light, and he exhibited the arrangement which he proposes to use for this purpose. The action of light of different degrees of refrangibility was then exhibited, by allowing the light from several parts of a spectrum of the electric lamp produced by a bisulphide of carbon prism to fall on the metal, the remainder being cut off by means of a screen, in which there was a narrow slit. The violet light gave a deflection of about two divisions on the screen, the greenish yellow four, the orange red five and a half, and the deep red nine divisions. The effects produced by the greenish yellow and the deep red are at times nearly equal. It may easily be shown by raising the temperature of the metal that the effect of light on its conductivity is essentially the same in kind at a low and moderately high temperature. The fact that light and not dark heat produces the observed effect has been shown by sending the beam through solutions of iodine in bisulphide of carbon. A very small effect on the metal was always observed, but this may be assumed to have been due to light, as in all cases it was possible to see the form of the carbon points through the solution. This fact may also be strikingly shown by exposing selenium through which a current is passing to the flame of

a Bunsen burner, first, when in its ordinary condition, and afterwards with the air openings at the base closed. It was shown that, whereas in the first case the effect produced was equivalent to three divisions of the scale, in the latter case one-tenth of the current produced by the exposure deflects the needle to the end of the scale. Prof. Johnstone Stoney then explained the theory which he has suggested in explanation of the phenomena observed in the radiometers of Mr. Crookes, which has been published in the *Philosophical Magazine* for the current month. The theory rests on the supposition that there is an excessively small trace of residual gas in the sphere in which the moving discs are enclosed. When the apparatus is exposed to heat the blackened side of the disc is slightly warmed, and this warms a layer of air in contact with it. At the ordinary atmospheric pressure, Prof. Stoney assumes the layer so warmed to have the thickness of a sheet of paper, when the temperature of the disc is 20° C. above that of the surrounding air, and on such a supposition we may calculate it for any other pressure and temperature. If we diminish the pressure the thickness varies inversely as the pressure raised to the power $\frac{1}{3}$. Thus if the disc be raised $\frac{1}{10}$° C. above the surrounding air, and the exhaustion carried to the $\frac{1}{10000}$th of an atmosphere, the layer will have a thickness of more than a decimetre, and the effect of the air will then be peculiar. If the gas is of such a density that the glass envelope is beyond the range of this action, the gas beyond the limiting distance will be cold, but if the effect reach the glass, conduction will take place to it. There will then be a procession of warm molecules towards the glass, where they will be cooled down, and form a number of cold, slow-moving molecules, which will go back to the disc and beyond it. And these processions will be intermixed with molecules taking no part in the action. In consequence of this, very few members will travel far in their paths; a portion of the motion of each, however, will be carried forward in the right direction. So long as these processions go on, the slow-moving molecules which reach the front of the disc are thrown off more vigorously than from the back. Prof. Stoney considers the pressure thus produced to be that measured by Mr. Crookes. With a pressure of the gas of $\frac{1}{10000}$th of an atmosphere, an elevation of temperature of $\frac{1}{10}$° C. will produce the force actually observed, while if the exhaustion be carried to $\frac{1}{100000}$th the elevation of temperature necessary will be $\frac{1}{10}$° C. Thus with the greater pressure a lower temperature will suffice, but other influences will then be brought into play tending in an opposite direction. It was pointed out that on this theory the action may be considered as closely resembling electricity, and Mr. Crookes has shown that the glass envelope is often itself slightly electrified.

Paris

Academy of Sciences, March 13.—Vice-Admiral Paris in the chair.—The following papers were read:—Observations of the moon made with meridian instruments of the Paris Observatory during 1875, by M. Leverrier.—Second note on the transformation of nautical astronomy, through the progress of chronometry, by M. Yvon Villarceau.—Observations of temperature at the Museum during 1875, with electric thermometers placed at depths of 1 to 36 metres in the ground; and *résumé* of ten years' observations, by MM. Becquerel. This *résumé* shows that the mean annual temperatures of the ten years increase regularly from 1 to 36 metres, at the rate of about one degree per 30 or 31 metres difference of level. An aquiferous sheet of 26 metres gave a slight excess of temperature. At 36 metres the temperature was constant and equal to 12°·42 (mean temperature at 1 metre = 11°·31).—On the siliciuration of platinum and of some other metals, by M. Boussingault.—On the flood of the Seine in February and March 1876, by M. Belgrand.—Observations on M. Resal's recent communication on steam-jacketing of engine cylinders, by M. Ledieu.—Note on water-pipes, by M. Boileau.—On the linear equations of the second order, of which the integrals are algebraic, by M. Jordan.—On the transit of Venus of Dec. 9, 1874, by M. André. The diameter of a star (of sufficient brightness) varies with the aperture of the instrument with which it is observed; the author verified this experimentally, and he draws some inferences relative to the transit observations.—On the eggs of Phylloxeras, by M. Lichtenstein.—On a process of direct application of sulphide of carbon in the treatment of phylloxerised vines, by M. Allies.—Treatment of phylloxerised vines with sulphide of carbon introduced and diffused in the soil by means of an aspirating apparatus, by MM. Crolas and Jobart. An iron tube, with terminal apertures, is inserted in the ground; air is drawn off through it by a pump, while sulphide of carbon is sprinkled over the surface; thus the vapour penetrates the soil. The cost is 320 francs per hectare.—On the employment of potash and of lime in treatment of the vine, by M. Demaille.—On the overthrow of the Grand-Sable at Salazie, by M. Vélain. The case was strictly analogous to that of landslips in Switzerland (not a volcanic phenomenon).—On a means of preservation against the accidents caused by fire-damp in mines, by M. Minary. The gas, being lighter than air, ascends, and M. Minary would make a series of vertical excavations in the roof to receive it, the apertures merely allowing the gas to enter and the air to escape. The collected gas could be drawn off to the surface by pipes. Should the gas in these reservoirs be largely mixed with air, he would place in them a system of porous tubes to separate it by endosmose, and these would be connected with the suction pipe.—Letter from M. Peters on the discovery of the planet (160) communicated by M. Le Verrier.—Observation of the planet (160) made with the garden equatorial, by MM. Henry.—Observations of same planet at the Observatory of Marseilles, by M. Borrelly.—On the approaching return to perihelion of the periodic comet of D'Arrest, by M. Leveau.—On polar auroras, by M. Planté. When the positive electrode of a strong secondary battery is brought towards the liquid surface of a vessel of salt water in which the negative electrode dips, you observe, according to its distance from the liquid, a corona of luminous particles round the electrode, or an arc bordered with a fringe of bright rays, or a sinuous line which rapidly bends to and fro on itself; the latter being especially similar to what one observes in auroras (like the undulation of drapery moved by the wind). Purple and violet tints appear as well as yellow. The liquid is greatly agitated, and steam rises more abundantly the further the electrode penetrates. Sound and magnetic perturbations are had, like those accompanying auroras. The negative electrode did not give the above phenomena, and auroras are probably due to a flow of positive electricity. Probably the imperfect vacuum in the upper regions plays the part corresponding to the negative electrode in the experiments, and the electricity comes from tropical regions.—Source of carbonic oxide, characteristics of formines, and of polyatomic alcohols, by M. Lorin.—On the canga of Brazil, and on the basin of fresh water at Fonseca, by M. Gorceix. Canga is a ferruginous conglomerate formed (according to the author) from *débris* of itabirites carried down by water, and cemented by ferruginous water.—On the causes which have brought about the retreat of glaciers in the Alps, by M. Gruner. From meteorological observations at St. Bernard, he finds that the period 1861-74, compared with the previous twenty years, shows an increase of mean temperature of 0°·92, a diminution of water of 0·204m., and, especially, a reduction of one-half in the falls of snow, 4·846m. instead of 10m. At Geneva, a similar change has been perceptible.—M. Cagnant called attention to a bed of kaolin at Saint Beaudelle, in the department of Mayenne. It would be well suited for manufacture of sulphate of alumina, which could be used for clarifying the Paris sewage water.

BLASIUS ON STORMS

Storms; their Nature, Classification, and Laws, with the Means of Predicting them by their Embodiments, the Clouds. By William Blasius, formerly Professor of the Natural Sciences in the Lyceum of Hanover. (Philadelphia: Porter and Coates. London: Lockwood and Co.)

WHATEVER may be thought of this work as a contribution to the extremely difficult question of the theory of storms, its delightful "positiveness of statement born of conviction," makes it a very readable book; and, further, the fresh facts contained in its pages, collected in most cases with evident care, form a useful repository to meteorologists in the study of atmospherical disturbances. In matters pertaining to general meteorology, the author is less at home as regards his facts, such as when he states that the heat of the sun's rays scarcely penetrates an inch into the surface of the land in the course of a day. He is also at fault as regards the seasonal distribution of atmospheric pressure over the globe, and the extent over which the south-west monsoon spreads to westward off the coast of Africa.

A storm is defined to be "in general the movement of the air caused by its tendency to re-establish an equilibrium which has in some manner been disturbed, and we may call all such movements storms, whether they are gentle breezes or furious hurricanes, whether they are accompanied by more or less condensation of moisture or clouds, or even by none at all; in general the laws of the motion and changes of the wind in re-establishing an equilibrium must be the same, whether the action takes place in a greater or less degree" (p. 43), and the author "is certain that the storm is the conflict of air-currents of different temperatures, and that the barometric depression is the *effect* of their movement" (p. 5). Thus storms are considered in a very broad sense,—in fact, they are regarded as synonymous with the whole atmospherical movements, and the book is therefore an attempt to state the theory of the circulation of the atmosphere.

Since the disturbances which occur in the distribution of the temperature and humidity of the air are either vertical or horizontal, it follows that the equilibrium will be restored either by the setting in of ascending or descending currents of air, or by the setting in of horizontally-flowing currents. Observation affords abundant proofs of the existence of all these types of aerial movements. In accordance with this conception of atmospherical disturbances and consequent movements which follow, Prof. Blasius classes all storms under three heads, viz.:—1. *Local or vertical storms*, which are stationary and centripetal, being produced by the atmosphere tending to re-establish in a vertical direction an equilibrium that has been disturbed; the characteristic cloud being the cumulus. 2. *Progressive or lateral storms* which travel, being produced by the atmosphere tending to re-establish in a lateral direction an equilibrium which has been disturbed. This second class of storms are of two kinds, viz., *equatorial or north-east storms* (winter storms), which are produced by a warm current displacing a cool one to supply a deficiency towards the poles, the temperature changing from cool to warm, the direction in which they travel being to the north-east quadrant, and their characteristic cloud being the stratus. *Polar or south-east and south-west storms* (summer storms), which are produced by a cool current displacing a warm one to supply a deficiency toward the equator, the temperature changing from warm to cool, the direction in which they travel being to the southern semicircle, and their characteristic cloud being the cumulo-stratus. 3. *Loco-progressive or diagonal storms* (tornadoes, hail-storms, sand-storms, waterspouts, &c.), which travel locally, are rotatory, and are produced by the atmosphere tending to re-establish the equilibrium of a polar storm which has been disturbed in the plane of meeting of the two conflicting currents by a peculiar configuration of the ground, their characteristic cloud being what the author calls the conus, instances of which are presented by the funnel-shaped cloud of waterspouts.

In the explanation offered of the most important of these classes, viz., the winter storms, their origin is attributed to an assumed distribution of atmospheric pressure from the equator to 80° lat. N., and to the polar and equatorial currents which result from this distribution of pressure, and which conflict with each other—the shifting of the atmosphere with the motion of the sun toward the north during spring and summer and toward the south during autumn and winter, taking place not regularly, but interruptedly, by repeated oscillations like the waves of the rising and falling tide. In the winter storm there is an area of lowest barometer marking the region where the equatorial current overlaps the polar current and the theatre of the cloud and rain which accompany the storm, with two regions of high barometer, one in front and the other in the rear of it. These three regions move forward thus:—The region of high barometer, which apparently moves far in front of the storm, is the receding polar current; the region of low barometer, the uprising current; and the region of high barometer, in the rear of the storm, the in-blowing equatorial current. It is asserted that the area of the storm, or the region of conflict between the equatorial and the polar currents, must assume the form of an ellipse, and not that of a circle, and that the air in a storm does not move around one centre, much less around the line when the *plane of meeting* of the polar and equatorial currents meet the earth's surface, but in straight lines from the circumference of the ellipse toward the region of the uprising equatorial current. The progressive velocity of the storm depends on the greater or less resistance with which the polar current opposes the displacing equatorial current, since the greater this becomes during the development of the storm, the more the plane of meeting must rise or approach a vertical position, and thus the progressive velocity of the storm be proportionally retarded.

It is unnecessary to follow Prof. Blasius through his theory of the atmospheric movements comprehending our winter storms, which we have stated as far as possible in his own words. It may be enough to point out that at least those regions of the globe with whose meteorology Prof. Blasius does not appear to be very familiar, present facts not in accordance with his theory, proving that storms do not necessarily arise from great currents which can be traced to equatorial or sub-tropical regions on the

one hand, and to polar regions on the other, or even to have had their origin in these regions; and that the idea of two great atmospheric currents having in storms a common *plane of meeting* (Begegnungs-fläche) is a mere supposition. Such statements as these: "The storm is the *conflict* of air-currents," and "the barometric depression is the *effect* of their movement," are, to say the least, altogether unwarranted in the present state of our knowledge.

The tornado is conceived as originating from the sultry calm felt before it, which is due to the conflicting of the two aerial currents, bringing about a state of equilibrium by the great compressive force they exert against each other. This equilibrium is disturbed by a particular uneven configuration of the earth's surface, and the disturbance produces the tornado. Leaving out of view the imagining action of conflicting aerial currents, it will be enough to point to the geographical distribution of tornadoes as disproving this theory of their origin.

Notwithstanding these very serious drawbacks, the book will repay perusal as being the production of one who not unfrequently gives evidence of acute observation, and who has thought out his subject for himself. The following may be given as specimens of what are repeatedly to be met with:—"Meteorology is fully as much a science of the earth's surface as of the air." "The wind changes, not by the veering around of one and the same current, but by a succession of different currents, blowing inwards." "Among the meteorological elements the real direction of the wind is the most difficult to arrive at, especially at observatories above cities or near mountains and coasts, and wind observations are therefore in general the least reliable." "The thermometer, as measuring a primary effect, is, with the hygrometer, at least as important as the barometer."

The theory of atmospheric movements remains still to be stated, and it needs scarcely be added that this cannot be done till we have a better knowledge than we yet possess of the physics of the atmosphere with its vapour, and of the merely mechanical effects of ascending, descending, and horizontally-flowing currents of air.

ANDERSON'S "MANDALAY TO MOMIEN"

Mandalay to Momien: A Narrative of the Two Expeditions to Western China of 1868 *and* 1875, *under Col. E. B. Sladen and Col. Horace Browne.* By John Anderson, M.D., F.R.S.E., &c., Curator of Imperial Museum, and Professor of Comparative Anatomy, Medical College, Calcutta. With Maps and Illustrations. (London: Macmillan and Co., 1876.)

MANY details concerning the latter of the expeditions referred to in this volume have been made known in this country through the daily papers, in connection with the much-to-be regretted murder of Mr. A. R. Margary. Indeed, Dr. Anderson states that his work was suggested by the interest called forth by the repulse of the recent mission and the tragedy attending it. The principal object of both expeditions was to prepare the way for establishing an overland trade-route between Burmah and China, and thus save the delay and expense of a roundabout sea voyage. That the establishment of such a route is desirable from a commercial point of view is maintained by all who have a knowledge of the circumstances, and in the meantime appears to have been frustrated by the machinations of native traders who think it their interest to shut out British enterprise from a field which is evidently capable of great development. This uncivilised shortsightedness will no doubt in the end be defeated, though in the meantime it has cost this country the loss of a brave and accomplished servant.

Dr. Anderson, who was medical and scientific officer to both expeditions, does not pretend to give in the present volume more than a narrative of the general work of the expedition; a full and illustrated report of the natural history results, is, however, we are glad to learn, in active preparation, and will be published by the aid of the Indian government. Meantime, in the very interesting narrative before us, numerous details will be found of value from a scientific point of view. Dr. Anderson has made use not only of his own notes, but to some extent of those of other members of the expeditions, and has evidently studied with care the results achieved by the French expedition from Saigon to Yunnan under Lagrée, Garnier, and Carné, as well as the literature of the subject generally. The result is that the reader will obtain a clear account of the British connection with the route referred to, and be in a position to understand the present state of affairs and future negotiations.

The real starting-point of the first expedition under Col. Sladen, was Mandalay, the capital of Burmah, which was founded by the present king only in 1853, but which is already a large and evidently well-constructed city. An interesting description of Mandalay, and of the royal court, and some of its customs, is given by D. Anderson. From this point the party sailed in a steamer up the Irawady to Bhamo, which is about thirty miles from the boundary between Burmah and Yunnan, and is the headquarters of the Chinese traders who seem at present to monopolise the trade between Burmah and Western China, and whose opposition had no doubt much to do with the difficulties encountered by both expeditions. After many troubles with regard to carriers the expedition left Bhamo and proceeded by Ponline, Ponsee, Manwyne and Nantin to Momien, beyond which it could not proceed.

Yunnan was at the time in a state of anarchy caused by the rebellion of the Panthays, or Chinese Mohammedan population of this region, which added greatly to the difficulties and dangers of the expedition. Nevertheless, even from a commercial point of view, it seems to us much was accomplished, but probably more from a scientific point of view. The natural history results, we have said, are being prepared for publication, but in the present volume the geologist, and especially the ethnologist, will find a great deal that is valuable and interesting. Dr. Anderson has evidently taken careful notes as he journeyed along, and a somewhat minute description of the course of the Irawady and of the country on its banks, and its antiquities between Mandalay and Bhamo will be found in the work. There were so many delays between Bhamo and Momien that Dr. Anderson had many opportunities of studying the country and the people, and these he evidently took ample advantage of. To the Kakhyens and Shans especially he paid great attention, and his account of these peoples must be considered a valuable contribution to ethnology.

The Kakhyens especially are a very interesting race. They inhabit the mountains on the border-country between Burmah and China, and Dr. Anderson considers them as cognate with the hill tribes of the Mishmees and Nagas. The name Kakhyen is a Burmese appellation, and the people are widely spread under other names, as Singphos, Kakoos, &c. They do not seem, however, to be a genuine aboriginal population in Burmah and China as so many hill-tribes are elsewhere.

"By their own account the hills to the north of the Tapeng, for a month's journey, are occupied by kindred tribes. South of the Tapeng, they occupy the hills as far as the latitude of Tagoung, and, as mentioned, were met with on our voyage near the second defile. To the east, they are found occupying the hills, and, intermixed with the Shans and Chinese, almost to Momien. Here they, as it were, run into the Leesaws, who may be a cognate,

Kakhyen Men.

but are not an identical, race. The two chief tribes in the hills of the Tapeng valley are the Lakone and Kowrie or Kowlie, but numerous subdivisions of clans occur. All are said to have originally come from the Kakoos' country, north-east of Mogoung; and Shans informed us that two hundred years ago Kakhyens were unknown in Sanda and Hotha valleys. To give one instance of their migrations. The Lakone tribe have at a very recent period driven the Kowlies from the northern to the southern banks of the Tapeng. A Lakone chief, having married the daughter of a Kowlie, asked permission to cultivate land belonging to his father-in-law; receiving a refusal, he took forcible possession, and drove the Kowlies across the river to the hills where they now dwell."

The Kakhyens are divided into numerous tribes or clans, between which there does not appear to be any strong common bond of union. Indeed, in very many respects, the system of government, if it may be so called, which exists among these half wild tribes, reminds us strongly of that which prevailed in the Scottish Highlands in the so-called "good old times," before the abolition of the hereditary jurisdictions. They have many curious superstitions and customs, which Dr. Anderson describes with great minuteness. Everything in "the heavens above, the earth beneath, and the waters under the earth" seems to have its particular "nat" or spirit; "every accident or illness is the work of some malignant or vindictive one of 'these viewless ministers.'" The will of these "nats" is consulted by means of a medium, who works himself up into a state of great agitation, so as to become "possessed." The Kakhyens are not very bold warriors, though they are great braggarts, and very troublesome to deal with. They are altogether a very interesting people.

With regard to the wide-spread Shan race, also, many details will be found in the volume, the result both of Dr.

Kakhyen Matrons.

Anderson's own observation and of the observations of previous explorers. The Shans of Yunnan belong to the Tay-Shan or Great Shans of the Tai-race, the branches of which, under different names, are found extending to the eleventh parallel, their various states being tributary to Siam, Burmah, and China. The Shans of Burmah have become closely assimilated to the Burmese in all respects; the Yunnan Shans are the remnants of the Shan Kingdom of Pong, conquered by the Chinese in the fourteenth century, and which included part of Burmah.

"The Shans proper of these valleys are a fair race, somewhat sallow like the Chinese, but of a very faintly darker hue than Europeans, the peasantry, as a rule, being much browned by exposure; they have red cheeks, dark brown eyes, and black hair. In young people and children, the waxen appearance of the Chinese

is slightly observable. The Shan face is usually short, broad, and flat, with prominent malars, a faint obliquity and contraction of the outer angle of the eye, which is much more marked in the true Chinese. The nose is well formed, the bridge being prominent, almost aquiline, without that breadth and depression characteristic of the Burman feature. The lower jaw is broad and well developed; but pointed chins below heavy, protruding lips are not infrequent. Oval faces laterally compressed, with retreating foreheads, high cheek-bones, and sharp retreating chins, are not infrequent; and the majority of the higher classes seemed to be distinguished from the common people by more elongated oval faces and a decidedly Tartar type of countenance. The features of the women are proportionately broader and rounder than those of the men, but they are more finely chiselled, and wear a good-natured expression, while their large brown eyes are very scantily adorned with eyebrows and eyelashes. They become much wrinkled by age, and, judging from the numbers of old people, appear to be a long-lived race. They are by no means a tall people, the average height for men scarcely reaching five feet eight, while the women are shorter and more squat in figure.

A minute account of these people, their manners, customs, dress, &c., is given by Dr. Anderson. Some of the ornaments worn by the women are of most artistic workmanship.

The latter part of the volume contains a clear account of the second expedition undertaken to open a trade route between Burmah and China, but which, as we have said, came to an untimely and sad end about a year ago in the murder of Mr. A. R. Margary. Dr. Anderson sets forth the whole circumstances with evident fairness, and yet it is difficult to say exactly who was to blame in the matter. That such a trade-route as it was attempted to establish would be of great advantage to all concerned, there is no doubt; and no doubt also it only requires time to establish it. There is yet a very great deal to be learned both with regard to the natural history of that part of the world, and with regard to the several interesting races of people which form its population. Dr. Anderson's work is a valuable contribution to such a knowledge, and the clear and straightforward manner in which he writes adds greatly to the intrinsic interest of the information with which his pages teem. The illustrations of the country and the people are charming, and the two maps enable the reader to follow satisfactorily the footsteps of the explorers.

OUR BOOK SHELF

A Class-book of Chemistry. By Edward L. Youmans, M.D. (London: Henry S. King and Co., 1876.)

"THIS book is not designed as a manual for special chemical students. It aims to meet the wants of that considerable class, both in and out of school, who would like to know something of the science, but who are without the opportunity or the desire to pursue it in a thoroughly experimental way. Such a class-book as the present . . . . must be but a brief compendium of general principles and descriptions of the most important substances, and is not to be judged of by the fulness of its details." This extract from the author's preface sufficiently explains the objects which he has had in view in compiling the book before us. Certainly the work has no claims as a textbook for students; for the general reader we are afraid it will prove of little interest. Within the compass of about 350 pages we have an account of Gravity, Heat, Molecular Attraction, Electricity and Light, besides Chemistry proper. Surely the day has passed when this kind of thing could be tolerated in a book which professes to teach science. People cry out against the teaching of science as a regular part of educational discipline. It is all very well in its own place, they say, but the only true mental training is to be derived from a study of classics.

If boys and youths devote years to the careful study of ancient languages, they can scarcely fail to receive at least some benefit. If, on the other hand, they pass rapidly through a course of training (?) in science, with the aid perhaps, of such a book as that before us, they quickly forget what they have learned, and, so far as mental training is concerned, they had better have left science alone altogether. Our chief objection to the present work is that it seems calculated, probably unconsciously calculated, to further the delusion that science is a thing to be taken up in a leisure hour, but not a thing the study of which requires, while at the same time it increases, every activity of the mind. If the study of science is to be made a discipline, that study must not be pursued in the spirit of Dr. Youmans' book. The student must not content himself with a superficial knowledge of a few facts, nor even with gaining one or two generalisations; he must be taught to amass facts on the basis of his own observation, to separate the more important from the less important facts, to classify these facts and at last to rise to a generalisation which shall enable him to group together and so explain what had appeared to be isolated phenomena. Dr. Youmans' book can afford the student little help in such a process as this.

Of course it must be admitted that there is a large class of people who have neither leisure nor inclination to make science a study, but who are nevertheless desirous, and properly desirous, of knowing something of what science has done and of the way in which she has accomplished her work. Such people will, we are afraid, receive but little enlightenment from the work we are noticing. There is just sufficiency of detail to make the whole subject appear uninviting, but not enough to make the book valuable to the student. The mass of isolated facts is too great for the ordinary reader; he would soon, if not bewildered, become fatigued.

A book designed for the purposes stated in the preface to the present work requires to be written more from the standpoint of some central idea, round which is grouped together such a number of facts as may serve to illustrate and enforce that idea. The relation of the facts to the general theory and of the theory to the facts may then be made the means of inculcating a certain amount of true scientific training.

While we thus complain of the general scope of Dr. Youmans' book, we must give the author praise for the manner in which some parts of his work are written, more especially the chapter on theoretical chemistry. The chapters on descriptive chemistry are exceedingly meagre in details, but pretentious in the ground which they *appear* to cover.

M. M. PATTISON MUIR

Injurious Insects of Michigan. By A. J. Cook, of the Michigan State Agricultural College. Fourth Report of State Board of Agriculture for 1874.

THIS useful and instructive pamphlet is to a great extent compiled from the writings of Messrs. Riley, Fitch, Le Baron, Walsh, Harris, Curtis, and Packard. It is illustrated by numerous woodcuts from the able pencil of the justly celebrated Prof. Riley, of Missouri. Its object is to enlighten farmers, gardeners, and fruit-growers of the State of Michigan, as to the general appearance, structure, and habits of noxious insects; at the same time suggesting means by which the increase of these pests to agriculture may be arrested. The "Colorado Beetle" and the "Grape Phylloxera" occupy a conspicuous place among these enemies of man.

The pamphlet winds up with a valuable hint to house-

keepers whose carpets are in danger from the attacks of the Clothes Moth. "Take a wet sheet or other cloth, lay it upon the carpet, and then run a hot flat-iron over it, so as to convert the water into steam, which permeates the carpet beneath and destroys the life of the inchoate moth."

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Water-supply of the Metropolis

I HAVE no intention of entering into a controversy in your columns with my friend Dr. Frankland, but his letter in your impression of March 16 seems to require some reply.

When I made the remarks which are called in question by Dr. Frankland, I was careful to say that I might not unfairly be accused of having done so from interested motives, an admission of which no one who reads Dr. Frankland's letter can say that he has not taken the full advantage. I am not ashamed of my occupation, and am quite ready to admit another historical parallel afforded by Jack Cade, and confess that I, or those who have gone before me, "against the king, his crown, and dignity, have built a paper-mill." But, whether paper-manufacturers "in the exercise of what they call their rights" are polluters of streams or no, is a question into which I never entered, and is entirely beside the points which I raised.

These are in the main avoided by Dr. Frankland. The two Commissioners, a portion of whose report I criticised, and of whom it is as well to observe Dr. Frankland is one, recommend that the Thames and the Lea should be entirely abandoned as sources of supply for domestic use in London, and particularly refer to the Chalk in the neighbourhood of London, and not to the distant springs of the upper Thames as the future source of supply. In his letter to you Dr. Frankland states that "The Commissioners advise that the drinking water of London should continue to be derived from its present sources, but that it should be led away to its destination before it is mixed with the sewage of Oxford, Reading, Windsor, and other towns, and before it is fouled by the filthy discharges of paper-mills, and by other disgusting refuse." I presume that these two statements can be reconciled, but looking at the proposal that the water should be procured "within a moderate distance of London" the calculations as to the area of 849 square miles of Chalk and Upper Greensand within thirty miles of London, and looking at the enormous expense of conveying water more than thirty miles, I took that radius as representing the area out of which some district was to be placed under unnatural conditions with regard to its springs and streams, in order to supply our vast metropolis, which I am told it is contemptuous to term "overgrown." I never spoke of the fertile meadows of the Thames valley, about which Dr. Frankland makes merry, and I never intentionally alluded in the slightest degree to the main valley of the Thames, except to say that both below and above London there might be spots in it from which a limited supply of water might be pumped without much injury to the neighbouring property. My comments were intended to be confined to districts in which the proposal of the Commissioners could be carried out of sinking wells below the present spring-heads, and so constantly drawing upon them that there should be always a void below the level at which the drainage naturally escapes. If this does not mean the drying up of the streams by cutting away their natural sources of supply I shall be glad to know what it does mean.

If Dr. Frankland were as well acquainted as I am with the gravelly soil of some of the low meadows in Chalk districts, he would cease to be surprised at the possibility of their being converted into "arid wastes" by the abstraction of the water with which they are now charged up to within a very few feet of their surface. In the valley in which I live I have known the peaty soil above such gravel, even without the artificial abstraction of the moisture below, become during a dry summer sufficiently arid accidentally to catch fire and continue burning for days.

But then I am told that the wealthy City of London would be able and willing to pay for any damage it might inflict in procuring its water supply. I can only say that the word "compensation" does not occur in the Index to the Report of the Rivers Commissioners, and I have sought in vain for any allusion to it in the text. Perhaps Dr. Frankland is not aware that at the present time the state of the law is such that even when compensation has been provided for by Act of Parliament, it has been held to be inapplicable in the case of wells being dried, on the ground that an action will not lie in respect of the loss of underground water, and therefore that no statutable damage has been inflicted.

As to the prescription for increasing the supply of spring water in a Chalk district by lowering the level of the subterranean reservoir, I may observe that in most of such districts floods are almost unknown, the soil being sufficiently absorbent to imbibe all the rain that falls, except when by chance the surface is frozen. The lowering of the water which, except in the valleys, is now usually from 100 to 200 feet below the surface, would make no difference in the receptive power of the soil on the hills, and could not be effected in the valleys without laying the streams, which now flow through them, dry.

As to London encountering the expense of a separate water supply for dietetic purposes, I can only say that if it can be effected for 2,000,000*l.*, as suggested by Dr. Frankland, it will, in my opinion be far cheaper than the plan the Commissioners advocate. It is as a rule more economical to make use of what we have, than to discard all existing appliances and commence on a new system. Perhaps the Water Companies may have a word to say on this point.

The concluding paragraph of Dr. Frankland's letter seems to have been written under some misapprehension. I distinctly stated that "if we refer to the headings of Organic Carbon and Organic Nitrogen there can be little doubt of the superiority of the Kent Company's water." I may, however, be under some misconception as to the statistics under the awful heading "Previous Sewage or Animal Contamination," in which, possibly, I do not stand alone. What I ventured to suggest was that the Commissioners on the Water Supply of the Metropolis, within whose proper sphere this question lay, were not altogether wrong in reporting, that with perfect filtration and efficient measures taken for excluding from the rivers the sewage and other polluting matter, the Thames and Lea would afford water which would be perfectly wholesome, and of suitable quality for the supply of the metropolis.

If this proved impossible, then I ventured to point out that there was already in London a sufficient supply of water of the kind recommended by the other body of Rivers Commissioners.

I must not, however, waste your space and your reader's time, but will in a few words mention my principal reason for taking up this subject, which, however, apart from any such reason, I considered would be of interest to geologists.

It was this, that in an otherwise admirable and exhaustive public report, measures were advocated involving in all probability great inconvenience and loss to large tracts of country, without, so far as I could see, one single reference to such loss and inconvenience. With the advocates of a private scheme such a disregard of injury to others would be reprehensible, though possibly not uncommon, but some greater consideration of the interests involved might fairly be expected from a public document.

JOHN EVANS

Nash Mills, Hemel Hempsted, March 18

Evidences of Ancient Glaciers in Central France

MANY lovers of natural history who have not the opportunity of seeing foreign scientific periodicals, may learn the advantage of taking such a paper as NATURE in the correspondence which was published between Dr. Hooker of Kew and the late Mr. Poulett Scrope, on the evidences of ancient glaciers in Central France.

The objections raised by Mr. Poulett Scrope, and the pleasure of examining such evidences as are adduced by Dr. Hooker, have induced me to accept the invitation of friends, who also enjoy such researches, to again visit Auvergne for the purpose of examining the Mont Dore valley for glacial traces, and I would gladly avail myself of any observations made by other geologists in that region, if they would do me the favour of sending me the notes of any localities to the address below.

In the meantime M. A. von Lasaulx, of Breslau University, claims the priority over Dr. Hooker in describing glacial traces in the *Ausland* periodical, in 1872, as occurring at the entrance of the "Gorge d'Enfer." I have also before me, as I write, a travelling note-book of Sir Wm. Guise, President of the Cotswold Naturalist Field Club (date, June, 1870), in which he refers

to observing "moraines," "ice-action," "boulders," and "*bloc perchés*" in the same region.

My object in sending these lines to NATURE is to ask for notes of localities where glacial traces may be seen, as an aid to those who hope to examine more closely into the glacial phenomena of Central France. W. S. SYMONDS

Pendock Rectory, Tewkesbury, March 25

Metachromism

A FEW words of explanation may seem necessary after Mr. Ackroyd's observations (NATURE, vol. xiii. p. 385) on my previous letter regarding the above subject.

The question as to whether a change of composition can be said to *produce* or to *accompany* changes of physical properties, is a matter of words which the chromium series does not affect, as the relative number of atoms of the two elements is the test of arrangement followed.

With regard to the two colour scales—one co-existent with alterations of composition, the other with alterations of temperature—I never wished to "criticise" Mr. Ackroyd's results, but solely to point out a resemblance which I had observed a few years ago, and which I was not aware that that gentleman had noticed. The two series need not necessarily be similar; and, whatever other reasons may exist for placing white in the ultra-violet, the question in hand is not whether the ultra-violet rays produce the same sensation on our eyes as a mixture of all the colours, but, Do the white compounds in question, when spectroscopically examined, *only* show the ultra-violet, leaving the rest of the range in darkness, or do they show a complete spectrum? If the first, then of course their place of classification would be in the ultra-violet; but if they give a whole spectrum (as the compounds do to which I referred), then they must be classed as having an average refrangibility greater than yellow light (because they have blue in addition to it), and less than blue light (because they have yellow also), for the centre of luminosity (on each side of which the total of light rays is balanced) falls in the green.

If we had only to deal with monochromatic substances, then of course the usual *pan-spectral* white would not need to be considered, and green (as Mr. Ackroyd says) would be the only appearance to be classed between blue and yellow.

Thus "the assertion that white comes between yellow and blue" does not "rest upon the colour relation found to obtain between the oxides of the alkali metals," though it is in accordance with the rule given on p. 347, in the six sets of the oxides and chlorides there mentioned; the sole case not agreeing with it being that of the chromium chlorides, which, however, may be accounted for.

As to the orange colour of Na_2O_2, as Miller does not mention any colour, Turner was referred to; and if he is in error, that one instance may be laid aside; in any case it does not affect the relative natural order of blue and white.

Bromley, Kent W. M. FLINDERS PETRIE

Socotra

WHEN I wrote the letter to the *Times* about Socotra, alluded to in NATURE, vol. xiii. p. 414, I was not acquainted with the excellent topographical memoir on this island by Lieut. J. R. Wellsted, published in the Geographical Society's Journal for 1835 (Journ. R. Geog. Soc. v., p. 129). After perusing it I am more than ever of opinion that Socotra is well worthy of the attention of the naturalist, and may probably possess many most interesting indigenous plants and animals. Unless matters are very different from what they were in 1834, there can be little difficulty in exploring the island, and if, as we are told, it has really become British property, I trust we may not have to wait much longer for some information about its zoology and botany. "Socotran Aloes" and "Dragon's Blood" are at present almost its only known natural products, and Lieut. Wellsted mentions but one native animal—a species of Civet.

Coloured Solar Halos

SOLAR Halos such as described by Dr. Frankland (NATURE, vol. xiii, p. 404), may be seen on about seventy-five or eighty days in the year, here, and are commonest in the spring, but it is extremely rare for them to be brightly coloured. I speak of the ordinary solar halo of about 22° radius, but the great halo of about 46° radius, is always distinctly coloured, though not a common phenomenon. It is not the "murky atmosphere" of London that hides the colours of the ordinary halo; they usually do not exist, except dull red and orange, and perhaps a faint tinge of blue. This is owing to the great breadth of the halo, which causes the colours to overlap and mix together; here it is very seldom that the halo is narrow and the colours consequently bright, as they seem to have been when seen by Dr. Schuster (p. 394). I doubt whether the name "parhelia," which he gave them, is correct; I understand that term to mean mock suns (or a bright small portion of a halo), a phenomenon visible here on thirteen days in a year on the average.

I may add that though I am rather easily dazzled, I find no difficulty in seeing halos with the naked eye.

Sunderland, March 28 T. W. BACKHOUSE

"Euclid Simplified"

MR. MORELL'S defence is a curious one, and amounts to this: "If my book is a bad one I am not to be blamed, because I have copied from Amiot, Legendre, and others. If I have made blunders in derivations, &c., again I am not to blame, but to be pitied, because I could not employ better printers." As in our former notice we limited our remarks to a few only of the objectionable features in "Euclid Simplified," so, in our present notice, we shall select a few only of the points put forward in Mr. Morell's letter, though we may observe in passing, that we see no reason to retract any of our previous comments. We think that our readers will agree with us when we state our belief that Mr. Morell has utterly failed in most, if not in all cases, to appreciate the force of our objections. Mr. M. correctly quotes Dr. Wormell (pp. 78-81), but fails to see that his own statement is widely different; had he written "perpendicular to the straight line A A′ through its centre" (p. 41), "perpendicular to A B through its middle point" (p. 42), we should not have found fault with him. Again, the reference to Mr. Gerard (p. 310) is not to the point; we can understand what is meant by a "segment capable of a given angle," but we still object to the term "capable angle." The revised definition of a *parallelogram* is now (see text and letter), "a quadrilateral of which the opposite sides are equal and parallel!" We did not object to the term *lozenge*, which is a well-known one, but to the way in which it was introduced.

We turned to Dr. Wormell's definition of *circumference* with some curiosity, and found that (with the exception of "plain" being printed for "plane") it was perfectly right, and that Mr. Morell had again failed to see the point in our citation of the schoolboy's definition. We contend that Amiot's sentence, as quoted by Mr. Morell, does not mean what Mr. M. makes it to mean. Dr. Wormell's use of G. C. M. is perfectly legitimate, but does not warrant, so far as we can see, the use of *R* for *right angle* (seeing it is conventionally applied to another purpose) unless, indeed, it be explicitly stated in the text that *R* is so used.

We said (p. 204) that in Theorem VI., p. 148, the reasoning is defective. Mr. Morell replies it "only errs by excess of proof." We will reproduce the "proof," and leave the decision to our readers. "The area of a trapezium A B C D is equal to the product of its height B E by the half sum of its bases A C and B D. Drop the perpendicular B E on A F, and *bisect it by line G H.* Produce the base A C to F, making C F = D B. Then the two triangles D H B and F H C which have for bases the base D B of the trapezium or C F = D B, and which have also the same height, $\frac{1}{2}$ B E, are equal. The area of triangle F H C = $\frac{1}{2}$ D B or F C × $\frac{1}{2}$ B E; that of triangle D H B = $\frac{1}{2}$ D B × $\frac{1}{2}$ B E. These triangles, having equal angles, are therefore equal. But," &c. Upon this we remark, we are not told *how* G H is drawn—the pupil is to infer that it is parallel to B D. Now we must suppose H connected with B and F, and cannot assume that B H F is a straight line, hence, though triangles H F C, B H D are equal, it does not follow that angles F H C, B H D are equal, hence too we cannot assume A B F to be a triangle. But really we must apologise for taking up space with such elementary details. For Mr. Morell's benefit we give the following:—Produce A C to F, making C F = B D, join B F, cutting C D in H, then triangles C H F, B H D are equal, and triangle A B F = A B D C, &c.

Enough has been written on this, in its present form, objectionable book. At any rate we hope that any one who has

thought of introducing the work into school use on the strength of one or two hastily written commendations of it, will be induced in consequence of what we have written, to examine the work for himself. We feel confident that any competent geometer who opens the book at almost any page, will endorse our criticisms, and say "the half was not told." In brief, the definitions are faulty, the enunciations are faulty, the proofs are faulty, and the typography is faulty; if these things do not make a bad book we do not know what does. The defence is, "if the enunciations are loosely and inelegantly worded, Amiot must bear the blame which attaches in a greater degree to our translations of Euclid." Alas! poor Amiot! this is an unkind cut, Mr. Morell! R. TUCKER

March 6

Bullfinches and Primroses

I HAVE a bullfinch which was hatched last summer after primroses were over. They were therefore quite new to him when I offered him the first I could get this season. He pulled it to pieces quite indiscriminately, biting stalk, flower, or calyx quite indifferently, and the same with a few more which were given to him at the same time. But since then he has often had a few at a time, perhaps twenty or thirty in all, and he now almost always bites out the lower part of the calyx, as described in NATURE, vol. ix. p. 482. Sometimes he bites a little too high up, but almost instantly tries again with better success. When that part is eaten he attacks the stalk rather than the corolla.

Last spring I offered primroses to four bullfinches belonging to friends. Not one seemed to pull the flower to pieces according to any method. Two of them I saw only once. Another (an old bird and somewhat shy), after being supplied with the flowers for several days, seemed as unskilful in picking out the tit bit as he was at first. The fourth was a young bird. His mistress was called away before she had heard what was the peculiarity for which I was watching. A few days later she told me she had been giving him primroses in the meantime, and had noticed that he ate only the green part. In those few days he had learnt the art of primrose eating, not indeed quite perfectly, but wonderfully well considering how little practice he had had.

C. A. M.

Seasonal Order in Colour of Flowers

IT seems that Mr. Thiselton Dyer has thought fit to conclude the different observations made on this interesting subject by copying a part of Sachs's "Text-book." He will, I hope, allow me to point out to him the latest researches respecting the influence of light on the colour of flowers, published by E. Askenasy, in the *Botanische Zeitung*, 1876, Nos. 1 and 2. This author made experiments with several flowers which had sufficient food at their disposal, and found that some of his flowers changed their colour when placed in the dark, while it was not so with others. Therefore it cannot be said that light has no influence. The cause of this difference, observes the author, has as yet not been explained; other experiments will have to be made to clear up this point.

I think the colour of most flowers is a thing that by continued inheritance during a very long lapse of time has become almost constant, and cannot be changed in a few weeks or months. Long-continued experiments with the same flowers and their offspring would, perhaps, show more considerable changes than Askenasy found.

So much for the point referred to by Mr. Dyer.

As to the seasonal order itself, a continuation of Mr. Alexander Buchan's observations would be necessary, and probably also experiments with the several parts of the spectrum to which the flowers are to be exposed.

As this letter was written, I read that of Mr. Wm. Ackroyd (NATURE, vol. xiii., p. 366); doubtless every one will expect with great interest his following note. J. C. COSTERUS

Amsterdam

Plant Fertilisation

SOME short time since I observed a rather curious case of plant fertilisation through the medium of insects, and thinking—as the subject is one which is attracting much attention from botanists at present—it might be interesting to some of your readers (more especially perhaps as occurring in this remote part of the world), I take the liberty of forwarding you the particulars in the hope that you can find a corner for them in your valuable journal.

Growing rather abundantly just on the coast here is a small shrub belonging, I believe, to the sub-order Coffeæ, having numerous small greenish flowers, the interior of the corolla tube filled with silky white hairs, and the style bent in a peculiar manner, so as to bring it to one side of the tube. I observed the anthers delusce before the flower buds open covering the stigmatic surface (which is simply a thickened continuation of the style) with pollen. I noticed that all the individuals of this species of shrub were visited by a kind of ant in large numbers, and as soon as a flower opened they began pulling out the hairs, lining the corolla tube, and often biting off the stamens also, in order to clear a way down to the nectar contained at the bottom of the tube. In doing so they often support themselves by clinging to the pollen-covered style with their posterior legs. The bend in the style which brings it to the side of the corolla tube prevents it from being an obstruction while they are obtaining the nectar, although, so eager are they to get it even to the last drop, that in a few old flowers I noticed even the style removed. The pollen keeps dry for a considerable time, so that cross-fertilisation is effected by the removal of pollen from the *stigma* of one flower to that of another.

We have here, therefore, several adaptations of structure and habit to ensure that end. The deluscence of the anthers while in the bud removes the pollen from a part of the flower where it would in all probability be wasted (when the ants bite off the anthers) to another part, where by a peculiarity in its structure, viz., the bend in the style, it is protected and transferred to other flowers. The hairs in the corolla-tube, by rendering the approach to the nectar difficult, and thus making the use of the style as a support needful, also increase the chances of cross-fertilisation. M. S. EVANS

Durban, Natal, South Africa, Jan. 25

The Visibility of Mercury

PERHAPS some of your readers may, like myself, have been struck with the remarkable brilliance of Mercury to the naked eye on the evening of January 26. I scarcely ever remember to have seen the planet so well deserving the epithet στίλβων. Since April, 1858 I have noticed it twenty-one times with the naked eye at its evening apparitions. It seems difficult to reconcile the lament of Copernicus that he would die without seeing Mercury with the accounts of his life. The common reason given is, that it was always enveloped, to him, amid the vapours of the Vistula. But he did not pass all his life in that part of Europe. At one time he went to Bologna and stayed with Dominic Maria, a professor of astronomy in that place. After this he proceeded to Rome, where he was made professor of mathematics, and where we find him actually engaged in making observations about the year 1500.

The amateur may look out for Mercury near the western horizon, after sunset, about the following dates:—1877, Jan. 10, April 29; 1878, April 10; 1879, March 26; 1880, March 7; 1881, Feb. 20; 1882, Feb. 2; 1883, May 6; 1884, April 18; 1885, March 31; 1886, March 15.

Tycho Brahe, who could not have enjoyed a very favourable latitude for picking up the planet, gives us the following notes in his "Historia Celestis":—

1585, Nov. 15.—"Apparuit hoc tempore matutino ☿ tanquam rubricunda quædam stella secundæ magnitudinis et mediæ, quasi 2 et 1 magnitudinis."

1590, March 1.—"☿ adamodum apparenter videbatur, instar stellarum primæ magnitudinis, adeo ut eam, quæ in dextro humero Orionis est, magnitudine visibili repræsentaret. Si ☿ diametrum visibilem feceris $2\frac{1}{2}'$, non inconvenienter se habebit."

1596, March 15.—"Erat hâc vesperâ apprimè serenum et mediocriter tranquillum. ☿ hâc vesperâ satis fuit conspicuus quippe cujus quantitas stellam inter primæ et secundæ magnitudinis referebat."

Measurements of the diameter of the planet are best obtained when it is seen in transit on the sun, of which there will be a very favourable opportunity for several hours on May 6, 1878. After this, it is doubtful whether we shall see Mercury on the sun again this century in England, as he passes off the solar disc on May 10, 1891, about half-an-hour after sunrise, and on Nov. 10, 1894, the ingress of the planet is only a few minutes before sunset. For a transit to be seen thoroughly from this country we must wait till Nov. 12, 1907, and Nov. 6, 1914, both of which will be visible throughout here.

SAMUEL J. JOHNSON

Upton Helions Rectory, Crediton, Feb. 21

How Typhoid Fever is Spread

The case recently reported (NATURE, vol. xiii. p. 331) by Prof. Frankland from a Swiss village, where the poison of typhoid fever is said "to have filtered through a mile of porous soil, but which had nevertheless lost none of its virulent properties," is certainly so striking that some further reference to authorities seems requisite. If it can be satisfactorily proved that this was the most likely and reasonable origin of the case, it will give additional weight to every endeavour for preserving our water supply from every conceivable impurity; but unless based on the opinion of a competent and skilled investigator of such cases, it will lay us open to the charge of receiving any similar statement that favours our view, however rash. As medical officers of health it is our duty frequently to trace the origin of cases of this disease, and my anxiety to have further information of this case will thus seem reasonable, and I hope will meet with some reply from the distinguished professor. J. MITCHELL WILSON

Rochdale, March

The Ash Seed Screw

MR. ALFRED GEORGE RENSHAW would like to know (NATURE, vol. xiii. p. 367) whether the pitch of the ash seed screw is that which would give most power to the propeller of a steamer.

There is no screw on the samara of the ash (*Fraxinus excelsior*) while it is green. The pitch of the screw, at the same date, differs on different trees, and also on different seeds of the same tree, and also on different parts of the same seed.

Why the wing generally becomes twisted as it dries is a very interesting question. But what seems to me the most remarkable fact about this phenomenon is, that in every case, and on all trees alike, the thread of the screw is in one direction; that direction being the same as in a cork-screw, or ordinary screw-nail.

All varieties of the wild oat (*Avena fatua*) and the fly oat (*Av. sterilis*) have long awns, which also in the green stage are straight, but which in ripening become twisted. And in these also, the direction of the screw is uniform and the same as in the ash seed; but the pitch of the screw is variable.

Are these facts the same in other parts of the country? Are the screws left-handed on the south of the equator?

Summerhill, Aberdeen, March 20 A. STEPHEN WILSON

OUR ASTRONOMICAL COLUMN

THE COMPANION OF SIRIUS.—Mr. Wentworth Erck, of Sherrington, Co. Wicklow, in a communication dated March 21, notes the fact of a considerable diminution in the angle of position of the small star accompanying Sirius, which was detected by Alvan Clark in January, 1862—since the earlier measures, and adds that he cannot now estimate it at more than 55°. This retrograde motion is a consequence of the theory of Dr. Auwers, supposing the *comes* to be the cause of the anomalous proper motion of Sirius, which has formed the subject of several elaborate memoirs by this eminent astronomer. His last elements of the presumed disturbing body, adapted to the form of double star orbits, are as follow:—

T	1843·275	Excentricity	0·6148
Node ...	61° 57′·8	Semi-axis	2″·331
λ	18° 54′·5	Period	49·399 yrs.
Inclination	47° 8′·7	Motion, retrograde.	

The following angles of position and distances are given by these elements:—

1862·0	Pos. 85°·4	Dist.	10″·10	1874·0	Pos. 65°·5	Dist.	10″·95
1865·0	„ 79·9	„	10·78	1876·0	„ 62·1	„	10·59
1868·0	„ 75·0	„	11·15	1878·0	„ 58·4	„	10·05
1871·0	„ 70·3	„	11·20	1880·0	„ 54·2	„	9·33

Dr. Auwers gives a comparison of his calculated angles and distances of the centre of gravity, with those of Clark's companion to 1867, the agreement being pretty close throughout. But there can be no doubt that the calculation has given the angle too great since that year. The Washington observations show the following differences:—

1872·25 ...	Position $(c-o)$	$+5°·6$ ...	Distance $(c-o)$	$-0''·40$
1874·18 ...	„	$+6·3$ ...	„	$-0·46$
1875·24 ...	„	$+7·2$ ...	„	$-0·72$

In the above orbit the limits of distance are 2″·31 at 1841·84 for a position of 302°·5, and 11″·23 at 1870·13 for position 71°·7, and Auwers remarks that under the former condition the angle changes one degree in ten days, while under the latter condition 233 days are required for the same diminution.

Our correspondent mentions that Lassell's "new star" (Mem. R. Astron. Soc., vol. 36, p. 18), "though exceedingly faint, was distinctly visible. Pos. circa 130°, distance circa 75″," with 7½ inches aperture power, 200. Lassell, 1865, January 14, found the position 127°·0, distance about one minute.

Dr. Gylden, from the meridian-altitudes of Sirius, observed by Sir Thomas Maclear at the Cape of Good Hope during the years 1836 and 1837 found for the annual parallax of the star 0″·193 (*Bulletin de l'Acad. de St. Petersbourg*, t. vii.). Adopting this value, Dr. Auwers finds for the mean distance between the companion and Sirius, 37 times the earth's mean distance from the sun, and for the masses of Sirius and companion 13·76 and 6·71 respectively, in units of the sun's mass. The parallax 0″·193 corresponds to 1,068,700 times the sun's distance from the earth.

D'ARREST'S COMET.—M. Leverrier's *Bulletin International* of March 18, contains the definitive elements obtained by M. Leveau for the next return of this comet to perihelion in 1877, with an ephemeris for every 20th day throughout the year, which sufficiently defines the circumstances of the next appearance. The whole of his long-continued investigations relating to the motion of this comet have been conducted by M. Leveau with extreme care and minuteness, so that by his investigations, in continuation of those commenced by M. Villarceau, the theory of D'Arrest's comet has been placed upon a similar footing of accuracy to that, upon which the theory of the periodical comet of Faye now stands through the labours of Dr. Axell Möller of Lund.

The next perihelion passage of D'Arrest's comet is found to occur 1877, May 10·339 M.T. at Paris, and the comet appears to attain its maximum intensity of light about a fortnight subsequently. Other elements of the orbit which apply to 1877, Jan. 14, are:—

		°	′	″	
Longitude of the perihelion		319	9	15	M. eq. 1880·0
„ „	Ascending Node ...	146	9	28	
„ „	Inclination	15	43	9	
„ „	Excentricity	0·6278048			
Logarithm of perihelion distance ...		0·1199444			

Motion direct.

The elements usually found in catalogues of cometary orbits are here substituted for others given by M. Leveau.

The semi-major-axis of the orbit is 3·54139, to which corresponds a sidereal revolution of 2434·2 days.

When this comet was last observed by Herr Julius Schmidt at Athens, on December 20, 1870, the intensity of light was 0·154; the greatest intensity attained in 1877, about May 26, is only 0·22, and it is certain that large telescopes will be required for the proper observation of the comet. When theoretically brightest, it rises at Greenwich less than two hours before the sun, and as this difference increases towards the end of the summer, the intensity of light is diminished by one-half. The comet will be nearest to the earth in the middle of October (distance = 1·40). M. Leveau promises in a subsequent communication a precise ephemeris for the whole year, and, it may be remarked, it very rarely happens that there is any necessity for predictions extending over so long a period.

PROF. HUXLEY'S LECTURES ON THE EVIDENCE AS TO THE ORIGIN OF EXISTING VERTEBRATE ANIMALS [1]

III.

IT will be necessary to preface our remarks as to the origin of the next highest group of Vertebrates—that of Reptiles—by some account of the distinction between them and the Amphibia, and by some observations on what zoologists mean by the terms "higher" and "lower" as applied to animals or groups of animals.

In external form there is little difference between such a reptile as a lizard, and such an amphibian as a newt, and there seems, at first sight, to be no reason why they should be placed in different primary groups. In former times, as a matter of fact, the essential difference between reptiles and amphibians was not seen, and the two were united into a single class; but modern researches have shown that, beneath this external similarity, lie great and important differences, the chief of which we must now consider.

In the first place, no reptile, at any period of its life, possesses gills, and, in consequence, the breathing of air dissolved in water becomes impossible. Nevertheless, reptiles, in common with all the higher animals, have, at one period in their existence, slits leading from the throat to the exterior, in precisely the same position as the branchial clefts of an amphibian, but functionless.

Secondly, certain organs, known as "fœtal appendages," are developed in connection with the young animal before it leaves the egg, and serve a temporary purpose in its economy. In the possession of these appendages, as well as in the absence of gills, reptiles agree with birds and mammals, and differ from fishes and amphibians.

The young reptile is produced from an egg of relatively large size, and consisting of a considerable mass of yolk, surrounded by a quantity of transparent "white" or albumen; the whole being invested by a hard or soft shell. The yolk does not divide as a whole, but the process of division is confined to a small patch on its surface; in fact, the reptilian egg answers to the amphibian egg, *plus* a quantity of additional matter, called accessory, or food-yolk, which is unaffected by the process of yolk-division. It is the small superficial patch, answering to the whole amphibian egg, which is converted into the body of the young reptile, the accessory yolk becoming gradually smaller and smaller, as its substance is used up in the nourishment of the embryo; in the meantime it forms a bag attached to the umbilicus of the embryo, and hence called the *umbilical vesicle* or yolk-sac; it is the first of the fœtal appendages, and the only one which occurs in any vertebrate below a reptile, being possessed by certain fishes.

After the embryo has attained a certain size, and has come to lie, like an inverted boat, on the yolk-sac, a fold grows up, all round it, from the surface of the yolk, and, the edges of the fold coming together above, a bag is formed enclosing the embryo into the interior of which a watery fluid is secreted, in which the little creature lies. This natural water-bed is called the *amnion;* it is the second of the fœtal appendages, and no trace of it is to be found in any fish or amphibian.

The third and last of these curious embryonic appendages, the *allantois*, grows out from the tail-end of the embryo as a pear-shaped body, solid at first, but soon converted into a sac, which extends round the embryo and yolk-sac, immediately beneath the membrane of the shell. The cavity of the allantois acts as a receptacle for the nitrogenous waste of the embryonic body, but its chief function is as a respiratory organ; for this purpose it is supplied by blood-vessels which form a close network over its outer layer, and the blood contained in these coming into close relation with the external air, through the porous shell, readily exchanges its carbonic acid for the atmospheric oxygen.

As the embryo grows, the yolk-sac becomes smaller and smaller, and is eventually completely drawn into the interior of the body of the young reptile, which by this time completely fills the shell. In many cases a horny knob is developed on the nose, and, with this, the now ripe embryo breaks the shell from the interior; the amnion and other membranes are burst, the allantoic circulation is stopped, the first inspiration is taken, and the little creature is born.

There are several minor points in which reptiles are distinguished from amphibia, amongst which we will only mention the articulation of the skull to the first vertebra by one condyle instead of two, the presence of a bone called the *basi-occipital* in the hinder part of the skull floor, and the fact that the branchial apparatus is reduced in the adult to the small *hyoid* bone or cartilage, which supports the tongue.

In what respects is a reptile a higher organism than an amphibian? When one animal is said to be higher than another, one of two things may be meant: its structure may be more complicated, as a carved platter is higher than a simple trencher; or its parts may be so arranged as to form a more complicated mechanism. The mere repetition of parts does not raise an animal in the scale; a worm with a hundred segments is no higher than one with ten, any more than a mill with ten pairs of stones is a higher kind of machine than one with a single pair. But if, instead of multiplying the number of millstones, two pairs only were used, one of which was adapted for coarse, the other for fine grinding, a machine of a far higher order would be produced, and it is a similar differentiation of parts for special uses and co-adaptation of structures to given purposes which raises an animal above its fellows.

Judged by this standard, a reptile is a decidedly higher animal than an amphibian; its skeleton, for instance, is a better piece of work, the joints being more neatly finished, and the whole mechanism much more perfect.

A third test is based on the facts of development. We saw that a frog, in the course of its development, went through a stage in which it was, to all intents and purposes, a fish, and that it was only after passing through this stage, as well as that of a branchiate amphibian, that it attained its higher adult character. Now the reptile stands in just the same relation to the amphibian, with regard to its development, as the amphibian to the fish. During the earlier stage of its growth it presents certain amphibian characters, such as the presence of gill-clefts; but these lower stages are passed over; the reptile goes beyond the highest amphibian in its development, and is therefore, in this respect also, to be considered as a higher animal.

At the present day there are four types of reptiles: the lizards (*Laartilia*), snakes (*Ophidia*), turtles and tortoises (*Chelonia*), and crocodiles (*Crocodilia*). We will now direct our attention to the first of these groups.

Most existing lizards have four well developed limbs, a long tail, a scaly armour, sometimes supplemented with plates of bone, and teeth, not set in distinct sockets, but firmly fixed to the jaw. The skull is so constructed that the hinder nostrils open far forwards into the mouth. The vertebræ have a peculiar and characteristic form, their articular surfaces being concave in front and convex behind, except in the Geckos or wall-lizards, and that remarkable New Zealand genus *Hatteria* or *Sphenodon*. The heart is composed of three chambers, two auricles and a single ventricle, the latter being again partly divided into two, and thus showing a slight advance on the amphibian heart, in which the ventricle is quite single.

Lizards are very abundant, especially in hot climates;

[1] A course of six lectures to working men, delivered in the theatre of the Royal School of Mines. Lecture III., March 13. Continued from p. 412.

most of them are land animals, a few only being inhabitants of fresh water, and one—the genus *Amblyrhynchus* of the Galapagos Archipelago—lives on the seashore, and, if hard pressed, takes to the sea.

Through the whole of the Tertiary epoch the lizards are essentially the same as those now existing. Some of the Secondary species, also, have the same characters, but in the chalk are found, in addition, strange marine lizards, such as the genus *Mosasaurus*, which attained a length of 30 feet. As far back as the Purbecks, the lizards have vertebræ like the existing kinds, but on descending to the Solenhofen slates we find abundant remains, which present the lower character of bi-concave vertebræ, and the same is true of all the still older forms, such as the *Telerpeton* of the Triassic sandstones of Elgin and the Permian *Protorosaurus*.

Thus the older lizards have a slightly simpler structure than those of the present day, but resemble them, on the whole, so closely, that we must conclude our existing forms to have been derived from the ancient ones, and have no need whatever to assume their special creation. Lizards, then, offer another example of what is meant by a persistent type.

A remarkable instance of this persistence is afforded by a case of quite the same order as that of Ceratodus, described in the first lecture. The Hatteria, mentioned above, differs from all other lizards in many particulars. Its jaws are armed with a horny beak, and its upper jaw has two rows of teeth, one on the maxillary, the other on the palatine bones; the teeth of the lower jaw bite between these, like a pair of scissors with a double upper blade. The vertebræ are bi-concave, and, along the belly, are placed a number of bony plates.

No other existing form whatever is known presenting these characters, but, about the year 1858, a number of fossils were discovered in the sandstone of Elgin, and amongst them the remains of a large lizard with bi-concave vertebræ, abdominal plates, a horny beak, a double row of upper jaw teeth, and, in fact, altogether like the existing Hatteria.

The crocodiles are the only other reptiles the history of which it will be possible to notice in this course. Two of the most important characters by which they are distinguished from lizards are, the lodgment of the teeth in distinct sockets and the position of the hinder nostrils or posterior nares. The maxillary, palatine, and pterygoid bones are so disposed as to form a remarkable shelf or partition in the roof of the mouth, thus bringing the posterior nares to the hindermost part of the throat. The soft palate forms a veil in front of these apertures, and hangs down so as to rest on the back part of the rudimentary tongue, and thus, except when the animal is swallowing, entirely shuts off the cavity of the mouth from the air passages. This arrangement has been prettily explained by the crocodile's habit of killing its prey by drowning; it is said that it can hold a captured animal under water, while its own nostrils—placed at the end of the long snout—are just above the surface, and thus is enabled to breathe freely, the air passing through the posterior nares, behind the veil of the palate, and so to the lungs, while its prey is being suffocated. This is an admirable explanation as far as the crocodile is concerned, but, unfortunately, it is probably untrue, for precisely the same arrangement is found in the Gavial and other crocodilians which live upon fish.

(*To be continued.*)

PHYSICAL SCIENCE IN SCHOOLS

PROF. ROSCOE has taken the right view when he says that science teaching in schools will remain unsatisfactory as long as it does not receive the same range and time as the subjects which at the present time preponderate so greatly. Granting the necessity of devoting more time to science, it follows, almost as a matter of course, that science teaching ought to begin at an earlier age than now. For else, where is the time to come from? The other alternative—to add a couple of years to the time required to pass through the present curriculum of a public school—would be accepted by very few parents. But there is no need for this alternative. The teaching of the elements of physical and chemical knowledge is most beneficially begun in early years. Some of the foremost thinkers of the scientific world assert and support this view, as may be gathered, for instance, from the Sixth Report of the Royal Commission on Science Teaching. I would mention, in addition to this, that Liebig strenuously advocated ("Chemische Briefe," Leipz. und Heidelb., 1865, 50th letter) the teaching of such elementary chemistry in *village schools* as bears upon the constitution of air, water, the ash of plants, and explains the process of combustion. The great German philosopher would hardly have done so, without being sure that the pupils will profit by the teaching. The average age of such a pupil is, I believe, twelve years, and he receives, as far as I am aware, no preparatory instruction in algebra or geometry.

It is surprising to find a man of the educational eminence of Mr. Wilson battling against early science teaching. I am inclined to ascribe his opinion on this matter to an incomplete view taken by him of the true significance science teaching has. Mr. Wilson considers the study of physical science as a means of developing merely the reasoning faculty of a boy, leaving out of sight the equally important function of calling forth and sharpening the faculty of *observation*. As for reasoning alone, certainly, the languages, and still more, mathematics, afford at least an equally good basis. It is just the circumstance that a sound teaching of science shows to the young mind the difference between evidence as resting (wholly, or to the greatest extent) on the *teacher's statement*, and evidence based on *facts put actually before the pupil*, which makes the study of science so valuable from a general educational point of view.

Early beginning of science teaching suggests itself for yet another reason. Everyone, with but the least experience in educational matters, knows that in order to be successful in instruction, one must repeatedly go over the same ground during the curriculum of a boy's education, and gradually expand the subject in the repetition. Why, then, shall not science, if it is to enter organically into the education of a boy, and not be merely tacked on to him, receive the same treatment? Let a boy at the age of ten or eleven begin with witnessing all the experiments which are usually performed in illustrating those sections of Chemistry and the science of Heat, that are required from the candidates of the London University Matriculation Examination. Let the boy become thoroughly acquainted with the *facts*, and let at this time as little theory be placed before him as possible. After such a course, which might be made to fill up two years, there should be a pause in the study of these branches of science for a year, or even two, before allowing the pupil to resume the same in a fuller and more theoretical way. The hours gained might be given to mathematics. Of course it would be out of place to give here anything like a programme of how the above idea should be realised; I must just content myself with throwing out the hint. After the initiatory course the pupil will be in better condition to follow later the theoretical parts than he is under the present system, where he has to overcome simultaneously the novelty of the facts and the difficulties of the theory.

Science acquired in this way will be very different from that which is hastily got up in the last six or eight months of a boy's stay in the school, and mostly, too, under the pressure and anxiety which accompany the preparation for some examination, say the London University Matriculation.

The scientific culture which pervades the educated classes of Germany is usually ascribed to the efficiency of the Universities; I believe it would be more correct to put it down to the sound education in scientific matters which the boys receive in the public schools, for it is only the smaller number who proceed to the Universities: the majority go after commercial and industrial pursuits.

R. GERSTL

University College School, London

ON DETERMINING THE DEPTH OF THE SEA WITHOUT THE USE OF THE SOUNDING LINE[1]

THIS is the title of a paper which has been presented to the Royal Society, and Mr. Siemens gave at the meeting of the 24th ult., a description of the instrument which he has designed with this object. He commenced by giving a mathematical statement of the effect of local attraction, to a certain depth, on a body placed at the surface of the earth, assuming it to be of uniform density, spherical in form, and unaffected by centrifugal action. For small values of depth (h), this attraction is $2\pi h$, the original formula from which this is adduced is :—

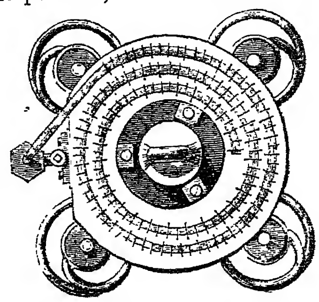
$$2\pi h\left(1-\frac{2}{3}\sqrt{\frac{h}{2R}}\right),$$

and by substitution of $2R$ for h in this, Newton's statement of the total attraction $\frac{4}{3}R\pi$ is obtained.

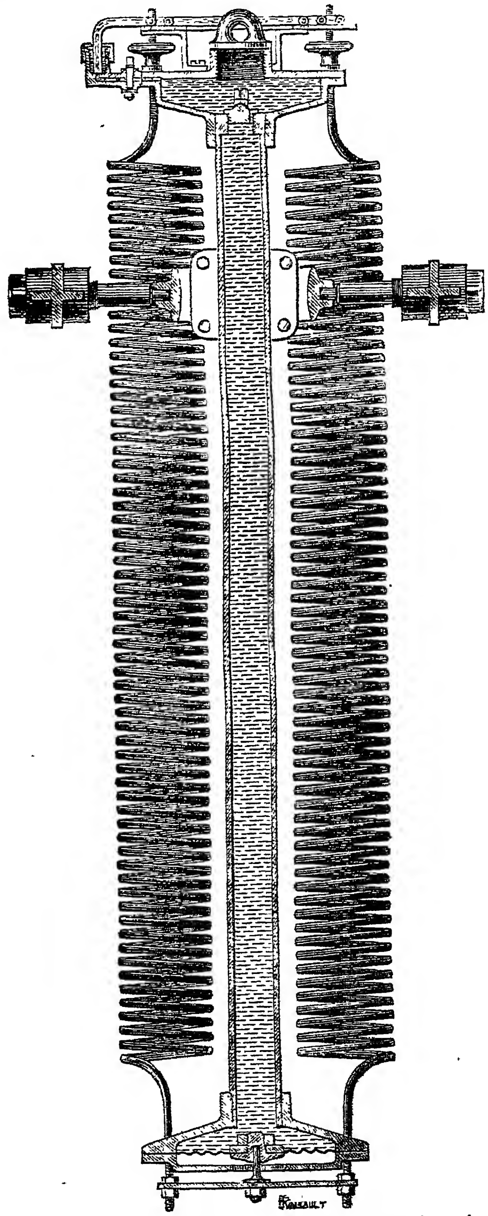
Now, if in place of the solid substance which forms the exterior crust of the earth, whose density may be taken to be the mean density of superficial rock, water, a material of less density is substituted, it is shown that the total attraction must be diminished, and the measure of this diminution is a measure of the depth of light substance which has been substituted for heavy. If we were in possession of the exact mean density of the earth, of that of the surface-rock, and of sea-water, a scale could be calculated beforehand, to show what depth would agree with a certain diminution of the measured effect of gravitation. Such an approximate calculation was made in designing the instrument, but Mr. Siemens has preferred to compare the readings of the instrument with actual soundings, in order to obtain a scale.

The instrument which is called a bathometer is represented in the accompanying illustration, and consists of the following parts: a weight being a column of mercury affected by variation of gravitation, a counterbalance being springs unaffected by variation of gravitation, and an arrangement by which the variations in gravitation can be read as depth in units. The column of mercury is maintained in a vertical steel tube having cup-like extensions, the lower portion being closed by a corrugated diaphragm of thin steel plate, and the upper portion containing an aperture for filling the instrument, having a screw stopper. The internal diameter of the tube is reduced at the upper portion, in order that the vertical oscillations of the mercury produced by the motion of a vessel in a sea-way, may be reduced to a minimum, and the instrument is suspended in a universal joint above its centre of gravity, so that it may always hang in a vertical position at sea, and is enclosed in an air-tight casing so that it may not be under the influence of atmospheric changes. The weight of the column of mercury is balanced at the centre of the diaphragm by the elasticity of the steel springs, and the *modus operandi* of the instrument is evident; as the mercury diminishes in potential through the effects of diminished attraction, the action on the springs diminishes, and these shorten upon themselves.

There are some peculiarities in the mechanical arrangement of the instrument which repay examination. Both ends being open to the air, its indications are not affected by variations of atmospheric pressure. With regard to temperature, the instrument is *parathermal*.



Its peculiar form has been the result of scientific inquiry. It was first discovered by experiment that well-tempered



steel springs diminished in potential with rise of temperature in a constant ratio, it was therefore necessary that

[1] By C. William Siemens, D.C.L., F.R.S.

the potential of the mercury should diminish in the same ratio. Mercury contained in a tube of uniform section would always have the same potential, for as it expanded and lengthened by heat, its specific density would diminish, and the product of density into height would remain constant. If contained in a tube of infinitely small diameter, compared with the diameter of the cup-like extensions, the height would remain constant, whilst the potential would diminish in the ratio of the expansion of mercury, but this is different from the ratio of the diminution of potential of the springs, and in order that these ratios may be accordant, or in other words that the equilibrium of the whole system may be the same at all temperatures, the peculiar form has been employed represented in the illustration, which is between the two forms already referred to.

The amount of the variation of gravitation with variation of depth is exceedingly small, and requires some method for indicating it. The method employed in the results hitherto tabulated and presented with the paper is by means of electrical contact, which is established whenever a sounding is to be taken, between the centre of the steel diaphragm and the end of a micrometer screw, which is at other times insulated from the body of the instrument. The screw is of such pitch, and the circular plate which turns with it has divisions so proportioned, that each division represents a depth of one fathom.

The readings of the instrument have been compared with soundings taken by means of Sir Wm. Thomson's steel wire sounding apparatus, and the accordance between the two is very satisfactory, especially as the bathometer, from the very nature of its action, gives a mean of the surrounding depths, whilst the sounding-line gives the actual depth below the ship. The reading of the instrument is also effected by means of a spiral glass tube, connecting by means of liquid, less dense than mercury, with the mercury in the upper cup; this arrangement has lately been tried and found to work successfully. The instrument is also available for the measurement of height; in mountain ascents, however, the elevated land will influence its readings, and allowance would have to be made for the effect of this local attraction.

The chief disturbing element in the use of this instrument is the effect of latitude, which will have to be ascertained approximately before its readings can be accepted as true indications of the depth. The difference between the total attraction of the earth at the pole and on the equator amounts to $\frac{1}{180}$ of its effect at the equator, the rate of increase in travelling from the equator to the pole being as the square of the sine of the latitude. The amount of this variation is easily calculable in fathoms of depth, to be tabulated for use with the instrument.

The principal value of the bathometer would be to serve the mariner as an additional means of determining his position when he was debarred from taking astronomical observation on account of the state of the weather. If the contour of the ocean bed were laid down on charts more perfectly than it is at present, and if these were in the hands of the mariner, he would be able to tell from his bathometer what was the depth of ocean below him, and whether that depth was increasing or decreasing in pursuing his course; he could also observe the rate of increase or decrease of depth, and in consulting his chart he would be enabled to determine his actual position with considerable accuracy, and thus be forewarned of the approach of danger.

PHOTOGRAPHY OF THE RED AND ULTRA-RED END OF THE SPECTRUM

IN 1874 Dr. Vogel communicated to the scientific public that he had been able to photograph the least refrangible rays of the solar spectrum by using what are known as the Uranium Dry Plates prepared by the Uranium Dry Plate Company. At the same time he experimented with other bromide plates, using dyes to give them distinctive tints. He then enunciated that the sensitiveness of the plates for the hitherto unphotographed portion of the spectrum was due to the colours employed, and apparently all his efforts have been diverted in elaborating this idea. Last summer I commenced a series of similar experiments to see whether the discovery could be made of practical use in photography; and have arrived at the conclusion, that the colouring matter gives this extended sensitiveness owing to the compound of silver formed and not to the colour itself, in fact, that the tint given to the film necessitates a very prolonged exposure. The additions of resins, nitro-glucose, and other similar compounds containing carbon to the bromized and bromo-iodized collodion soon convinced me that it was the organic salts of silver to which we must look for sensitiveness in the yellow red and ultra-red rays of the spectrum. Nearly every resinous body seems to prolong the photographic spectrum towards the ultra-red, and one or two in particular, also when the film is least colourless when viewed by transmitted light, that then it is probably in the most impressionable condition. Another point which is worthy of notice is, that a film dried from moisture, taking, in fact, the form of a dry plate, is always most readily acted upon by the ultra-red end of the spectrum. Probably this is due to the absorptive qualities possessed by the silver nitrate solution, and not really from an increased sensitiveness of the compound salts when dry.

If ordinary pyroxylin be employed for the collodion it is generally less suitable than if it contain a certain quantity of nitro-glucose, or other similar body; and it frequently happens if this be absent entirely that the photographic spectrum will stop short near *b*.

Taking a collodion made with pyroxylorin prepared at high temperatures and using the ordinary solvents (in the alcohol of which suitable resin and bromides are dissolved), it will be found in general that when the silver salts formed through them by the sensitizing bath, or by emulsifying them by direct addition of silver nitrate to the collodion, are presented to the action of the spectrum, the whole of it will be impressed with a developable image. With three prisms of 60° and one of 45° twenty minutes is sufficient exposure to give when the slit is nearly closed, a lens of four feet focus being used as the objective.

When this is overcome it will be possible (and I hope shortly to do so) to present a complete photographic map of those lines which lie beyond A to a distance at least equal to D – A, a point beyond which I have not as yet been able to obtain an image. The great difficulty to be encountered is that of finding a sharp focus for the different points of the invisible spectrum, the change in length from one point to another being very rapid.

Uranium and iron salts have also furnished me with spectra which are well worthy of notice. With the latter salt more especially the action of the heat-rays is very decided, though at present it seems to me that the exposure must be very prolonged.

I propose at a later date to give details of all the most interesting of these experiments sufficient to enable anyone to repeat them who may desire to do so.

W. DE W. ABNEY

P.S.—It may be as well to state that the best results with resin plates have been obtained when a modification of alkaline development has been adopted.

RAOUL PICTET'S SULPHUROUS ACID ICE-MACHINE

THE countries between the 40th degrees of N. and S. latitude have in general too temperate winters to admit of natural ice being obtained in any quantity; and yet these are the countries in which it is most required.

The high price at which it is sold prevents many people from buying it. It is for the purpose of rendering the supply of this useful and healthful article abundant and cheap that ice-making machines have been devised. These are of three classes, of which we shall give a brief account in order to show the advantages of the new invention, due to the ingenuity of a young Genevese physicist, M. Raoul Pictet.

The first class comprises the Ammoniacal Machines. These are based on the principle, applied by M. Carré, of the solution of ammonia in water. A saturated solution of ammonia is introduced into a boiler which is heated to 140° or 150° C. The ammonia is disengaged under strong pressure, and is liquefied in a condenser washed by a current of ordinary water. The liquid ammonia flows into the refrigerator, where it is evaporated and it returns into the liquid in a gaseous form. The evaporation is the source of the cold, which may be made very intense.

In order to work an apparatus of this kind, it is necessary that the first operation be effected, *i.e.*, the liquefaction of the ammonia in the condenser. For this purpose it is necessary that the pressure in the boiler correspond to the tension of ammonia vapour, at the temperature of the water of condensation, 30° C. at least in warm countries. This pressure is raised then to fifteen or eighteen atmospheres, an enormous pressure, liable to great danger.

Under so great tension the gas traverses cast-iron walls of two centimetres, the joints leak, not being air-tight, and the ammonia rapidly escapes from the apparatus. The alkaline solution must then be constantly renewed, which is very costly. There is another inconvenience. The fire under the boiler causes deposits, which, increasing day by day, give rise to the danger of an explosion. The fear of such a catastrophe demands constant watchfulness.

In countries less warm, with a water of condensation at 20°, the tension of the ammonia hardly exceeds eight atmospheres. In these circumstances the Carré machine works well and produces economical results. But in such countries natural ice is abundant, and the service rendered is consequently of less value.

The second class includes the Ether Machines. Sulphuric ether was first employed for the manufacture of ice in England. A large pneumatic pump draws up the vapours of ether, which are formed in a tubular refrigerator, and compresses these vapours in a condenser bathed in spring water. The evaporation may also freeze the water contained in the tanks, while the compression of the vapours and their condensation in the condenser transfer to the spring-water all the heat freed from the water in the tanks, transformed into ice. A pipe allows the condensed ether to return to the refrigerator, and be again subjected to volatilisation.

These machines, more simple than the ammonia ones, are, however, less workable. Ether is a liquid of small volatility, and gives only weak tensions. At – 4° or – 5° C., this tension varies from 4 to 8 centimetres of mercury according to the quality of the ether. The cylinder of the pneumatic machine must then be of considerable dimensions in order to draw up a small weight of ether and produce a limited amount of cold. The whole of the first half of the machine works with an almost complete vacuum, but if the joints, the walls of the tubes, and the caulking of the cylinder are not perfectly hermetic, atmospheric air will enter the apparatus; and should the manometer show that it is present to the extent of one or two centimetres, the evaporisation of the ether, will be arrested. With the smallest amount of air present the machine becomes unworkable; a hole no larger than a pin-point is sufficient to paralyse the half of its normal product.

Another inconvenience arises from the fact that ether is not a body perfectly constant in its chemical characteristics. Under the action of frequent changes of condition, of frequent volatilisations and condensations, it becomes acidified and transformed into less volatile isomeric bodies. On this account it is necessary frequently to change the active liquid, which is very troublesome and expensive.

Lastly, the greases with which the piston of the cylinder is lubricated form a close mixture with the ether, a mixture which is carried into all the apparatus, and which also tends to trammel its regular working.

The third kind, Compressed Air Machine, is the least workable of all, and has invariably failed on trial. Its principle is as follows:—Air is compressed in a large cylinder to nearly three atmospheres. This compression raises the temperature of the air to about 150° C. A current of water cools this air, which enters cold into a second cylinder, where it expands from three atmospheres to the ordinary pressure. This work which it produces upon a second piston is equal to the deduction of the original work, for the two cylinders are joined *en suite*, and are worked by the same rod. The air which is expanded lowers the temperature, and gives the second cylinder about 60° of cold. This air may be utilised to manufacture ice, or to cool cellars, apartments, &c.

This machine, in order to work well, requires large cylinders and close-fitting pistons with very little friction, a perfectly regulated introduction into the expansion cylinder, and orifices, valves, and flaps without a flaw. But these conditions are almost impossible to realise in practice. A piston of large size, travelling in a cylinder under a temperature from – 50° to – 60° C., is an abundant source of friction, for it is only imperfectly lubricated by glycerine. A thick coating, produced by the solidification of the vapour of water in the expansion cylinder, is also a cause of accident and trouble in the working. Lastly, the smallest derangement in the aspirating or compressing valves of the first cylinder puts an entire stop to the production of cold. These machines, therefore, are absolutely unequal to the practical solution of the problem.

A machine capable of easily performing the work must comply with the following five essential conditions:—1. Too great pressure must not occur in any part of the apparatus. 2. The volatile liquid employed ought to be so volatile that there will be no danger of air entering; *i.e.*, the pressure must be at least one atmosphere in order to be in equilibrium with the external pressure. 3. It is necessary to have a system of compression which does not require the constant introduction of grease or of foreign materials into the machine. 4. The liquid must be stable, it must not decompose by the frequent changes of condition, and it must not exert chemical action on the metals of which the apparatus is constructed. 5. Lastly, it is necessary, as far as possible, to remove all danger of explosion and of fire, and for this reason the liquid must not be combustible.

If we examine the series of liquids investigated by M. Regnault, only one will be found to satisfy these essential desiderata; this liquid is sulphurous anhydride, SO_2.

In fact, this body is liquid under the atmospheric pressure at a temperature of – 10° C., and it does not give pressures higher than four atmospheres at a temperature of 35°. This liquid does not act on metals or fats; it is not combustible, and is the least expensive of all known volatile liquids. By the process of manufacture discovered by M. R. Pictet, it costs less than sulphuric ether.

Thus, by taking advantage of the general principle of the evaporation of a volatile liquid to produce cold, and utilising sulphurous acid, we can obtain a machine which gives results constant in every country, and which acts in a perfectly mechanical and normal manner in all latitudes. The following is a brief description of a typical

machine, manufacturing 250 kilogrammes of ice per hour:—

A cylindrical tubular copper boiler has a length of 2 metres and a diameter of 35 centimetres; 150 tubes of 15 millimetres traverse its entire length, and are soldered by their extremities to the two ends. This first boiler is the refrigerator. It is placed horizontally in a large sheet-iron vat, which contains 100 tanks of 20 litres each. An incongealable liquid, salted water, is constantly circulating in the interior of the refrigerator by means of a helix. This liquid is re-cooled to about $-7°$ in a normal course, and it licks on its return the sides of the tanks which contain the water to be frozen.

In the space reserved between the tubes of the refrigerator, the sulphurous acid liquid is volatilised, its vapours are drawn up by an aspirating force-pump, which compresses them without the condenser. This condenser is a tubular boiler, the same as the refrigerator; only a current of ordinary water passes constantly into the interior of the tubes to carry off the heat produced by the change of the gaseous into the liquid state of the sulphurous acid, and by the work of compression. A tube furnished with a gauge tap, adjusted by the hand once for all, permits the liquefied sulphurous acid to return into the refrigerator to be subjected anew to volatilisation.

Sulphurous acid has the exceptionally advantageous property of being an excellent lubricant, so that the metallic piston which works in the cylinder of the compressing pump requires no greasing. Thus the introduction of foreign matter into the apparatus becomes entirely impossible.

The work necessary to manufacture 250 kilogrammes of ice per hour is at the most seven-horse power.

A cold of 7° in the bath is amply sufficient to obtain in the tanks a rapid and in every way economical congelation.

With these mechanical arrangements the following important advantages are realised:—1. The pressure never exceeds four atmospheres. 2. There is never any entry of air to fear, the pressures, as far as $-10°$ C., being always above that of the atmosphere. 3. The volatile liquid employed is perfectly stable, undecomposable, and without chemical action on metals. 4. All greasing in the machine is dispensed with. 5. The volatile liquid is obtained at a very low price, and it is accompanied by no danger of explosion or fire. 6. The cost of production of the ice approaches infinitely near to the theoretic minimum: it is about 10 francs per ton of ice.

By means of all these advantages the practical problem of the manufacture of ice may be considered as solved for all climates, and the process of M. Pictet will not fail to be speedily adopted in all warm countries as soon as it becomes known; it is in such countries that its happy results will be specially utilised and appreciated.

A small specimen of M. Pictet's machine will be shown at the forthcoming Loan Exhibition of Scientific Apparatus at South Kensington.

APPARATUS FOR DEMONSTRATING THE TRANSFORMATION OF FORCE

In a recent number of the *Journal de Physique*, M. Crova describes a convenient apparatus for showing the relations between heat, electricity, and mechanical force. The arrangement is as follows:—

Two of Clamond's thermo-electric generators are connected in surface, and put in communication with a Gramme machine in such a way as to set this in action. In the circuit is inserted a sort of electric lamp, in which a platinum wire placed in the centre of a small globe (which protects it from agitation of the air) can be raised to incandescence. The only difficulty of the experiment consists in so regulating the length and diameter of the platinum wire as that it may be raised to a red heat, while the thermo-electric current retains sufficient intensity to drive the Gramme machine. A circuit entirely metallic then is obtained, with which the following transformations can be effected:—

1. The Gramme machine being excluded from the circuit, a portion of heat, transformed into electricity by the thermo-electric pile, reappears in the state of heat in the platinum wire.

2. The platinum wire being excluded from the circuit, and the Gramme machine introduced, a portion of heat, transformed into electricity in the pile, produces mechanical work in the machine, which acts as a motor.

3. The platinum wire and the machine being included in the circuit, a part of heat, transformed in the pile into electricity, produces heat in the wire and work in the motor. If we then stop the motion of the Gramme machine, we find the incandescence of the platinum wire increased. The machine being liberated, on the other hand, is set agoing again, and the incandescence of the platinum wire diminishes in proportion as the motion is accelerated. In this way is rendered sensible to the eye the expenditure of heat necessary to develop an increasing quantity of mechanical work.

4. Taking the handle of the machine, we turn it *in the direction* of the rotation the current produces, but with an increasing velocity. In this way a velocity is reached such that the incandescence of the wire *completely disappears*.

5. If the handle be turned in a direction opposite to that of the rotation the current communicates, there is considerable resistance, and the incandescence of the wire *increases* rapidly; on turning more quickly, the wire is fused. Thus, in the metallic circuit under consideration, the circulation of a given quantity of energy may appear exteriorly in the form of heat or of mechanical work, the one of these quantities being the complement of the other. If by an exterior force we introduce into the circuit an additional quantity of work, the increase of the quantity of energy put in circulation is rendered visible by the incandescence of the wire; any communication outwards from the circuit, of a certain quantity of energy which circulates in it, appears, on the other hand, in diminution, or even disappearance, of the incandescence.

NOTES

Lord Salisbury, on Monday, named the following as Commissioners under the Oxford University Bill:—Lord Selborne (Chairman), Lord Redesdale, the Dean of Chichester, Mr. Mountague Bernard, Sir Henry Maine, Mr. Matthew White Ridley, and Mr. Justice Grove. The feeling among scientific men is one of intense disappointment, leading to the conclusion that it is useless any longer to consider whether Oxford will ever be in a position to do anything for the promotion of science.

The report of the Cambridge Board of Mathematical Studies to the Studies' Syndicate contrasts with the reports of most of the other boards in the paucity of its suggestions for improvement. They do not seem to think that very much is required in order to perfect the system of mathematical teaching. They believe in the probable stability and development of the system of inter-collegiate lectures, but say very little to assist its development, and they say nothing about the present vehement competition by means of private tuition, and the defective method of study that it induces. In answer to the question how University teaching may be organised so as to give the greatest encouragement to the advancement of knowledge, "the Board offer no suggestions under this head." Is this quite what might have been expected in a report bearing the signatures of Stokes, Cayley, Adams, Clerk-Maxwell, Sir W. Thomson, Tait, Lord

Rayleigh, and James Stuart? May there not be some unobvious explanation of this phenomenon? The whole report consists of only forty-one lines.

THE *Daily News* of Thursday last contains a letter from its *Challenger* correspondent, giving an account of the voyage from Valparaiso to Monte Video between December 10 and February 16. Most of the work of this cruise was done among the islands on the South American coast between the Gulf of Penas and the Straits of Magellan, and at the Falkland Islands. A considerable number of soundings were taken, and successful hauls made; the naturalists landed on several islands and made collections of specimens. This is the first part of the last section from Valparaiso to England, when the work of the ship will be completed.

MR. W. Spottiswoode, F.R.S., has been elected a corresponding member of the French Academy of Sciences, in the Geometrical Section.

ON the 21st inst. a fine bronze statue of the late Lord Rosse, erected in the principal street of Parsonstown, was unveiled. It is described as one of the latest and best of Foley's works.

GEOLOGICAL Time was the subject of Prof. McKenny Hughes' lecture at the Royal Institution on Friday evening. He told the audience that "A wise man before building a structure first examined the nature of the foundation," and he then proceeded to inquire into the nature of the evidence upon which the calculations have been made, as to the rate of denudation of valleys, the wearing back of sea coasts, the growth of peat-mosses, and the deposition of alluvium. He endeavoured to show by means of examples of exceptional phenomena, happening at long intervals and lasting for indefinitely short periods, that such calculations were utterly fallacious, and concluded by comparing our position to that of a "man in a cockle-shell boat, trying to sound an almost unfathomable ocean, firstly, with too short a line; secondly, with too heavy a weight; and lastly, with a weight so light that he was perfectly unaware when he touched the bottom." "To doubt," a great biologist tells us, "is the first principle of modern science," but in life, as in art, there are lights as well as shadows, and geological time is so intimately connected with the history of life upon our globe, and with the knowledge we possess of past denudations that have produced those missing leaves in the chapters of the earth's life history that geologist's call unconformities, that we venture to think that though we may not have reached the bottom of the deeper oceans, yet we have certainly sounded some of the most shallow seas. We therefore look forward with pleasure to hearing another lecture from Prof. Hughes, in which drawing on his abundant resources, he will leave the negative for the positive, the unknown for the known, and show us step by step the lights modern science has already thrown on the great cosmical, physical, and biological changes that are involved in the term "Geological Time."

AT the meeting of the Vienna Geological Society, on March 7, Mr. Hauer read a letter dated Manila, Jan. 11, 1875, from Dr. Drasche, who has been staying at the Philippine Islands since December 8 last, and intends to remain there for about six months longer for the purpose of investigating the active volcanoes and obtaining some knowledge of the geological composition of the island of Luzon. Four considerable excursions have been already made—1. To the plain of Pampanga, with the ascent of the Arayat and the Cordillera of Zambales. 2. The southern shore of the Laguna de Bey, ascent of the extinct volcano Maquilin, and a visit to the solfatara Tierra Blanca. 3. Ascent of the volcano Tael. 4. River Poray and Cueva de San Mateo. The wide fertile plain in which Manila lies is composed of clay strata recently raised from the sea, abounding with such species of fossils as are still living in the neighbouring sea. The plain is bordered by a range of hills, consisting of pumice-tuff. On the higher mountains behind these there are found trachytes and andesites, besides the tuffs. Of special interest among these is an amphibole-andesite, containing a great deal of olivine, that composes the Arayat. It is the most basic eruptive rock that Dr. Drasche has noted as yet on the isle of Luzon, and belongs probably to a more ancient volcanic period. On the Arayat, which had been hitherto considered as an extinct volcano, neither eruptive matters nor any other signs of distinct volcanic action are to be discovered. Near the River Poray there were found, besides greenstone-trachytes and conglomerates, large masses of a white limestone, partly crystalline and containing fossils, chiefly fragments of corals. When Dr. Drasche despatched his letter he was about to undertake a journey of two months to the wild northern regions of Luzon that have hardly ever been visited by geologist as yet.

DR. PARKES, whose death at the comparatively early age of fifty-six years we announced last week, was a man whose loss will be felt in many circles of society; he had connections with many scientific bodies, and, we believe, was universally known, beloved, and admired in the medical profession, for the scientific advancement of which he did so much. He served the State in various capacities throughout his life, but is specially known in connection with the Army Medical School, which owes a great part of its efficiency to his exertions and example. He had had a good training in scientific investigation, and his application of the principles of science to the conduct of research in his own department led to valuable results. Dr. Parkes was elected a Fellow of the Royal Society in 1861, and his contributions to its proceedings have been numerous and of high value. Among these we may mention his three papers on the Effects of Diet and Increase in the Elimination of Nitrogen during Muscular Action; in 1870, 1872, 1874, he also contributed papers on the Effects of Alcohol on the Human Body. Dr. Parkes, indeed, seems to have been a model of what a scientific physician should be, and to this he joined a character that attracted the love of all who knew him.

LETTERS received in Sydney from Signor D'Albertis, the Italian naturalist, we learn from the *Times*, who has been for some time resident on Yule Island, on the coast of New Guinea, give further accounts of the belt of coast land, twenty to twenty-five miles in width, of which he is able to speak, and so much of the land beyond this limit as was visible from the summit of a hill about 1,200 feet high. From this eminence he saw a large extent of plains, indented with lagoons, with the River Amama (the Hilda of the *Basilisk*) flowing downward from a northerly direction to its junction with the Nicura, which discharges its waters into the sea. Apparently, this stream is deep enough to be navigable far into the interior, but its channel is seriously obstructed by fallen timbers. He ascended the Nicura River for a distance of eighteen or twenty miles, and found it fringed with mangroves for the first ten miles, after which these gave place to splendid thickets of the Nipa palm, while the eucalyptus and the grass tree flourish at some distance from the stream. He crossed the Amama several times, and describes it as flowing through a large and fertile valley, apparently uninhabited, and well adapted for pastoral purposes. Nowhere did he find the natives possessing any knowledge of gold, silver, or any other metal. He confirms what has been said by Mr. Wallace and other travellers as regards the island being peopled by two races, the one mentally and physically superior to the other; the invaders having driven the indigenous tribes into the interior. The earlier inhabitants of New Guinea have darker skins than their conquerors, are shorter in stature, and their countenances are more prognathous than those of the coast tribes. The western

side of New Guinea appears to be chiefly inhabited by the indigenous Papuans, and the eastern by a superior race.

THE mail steamer *Congo* arrived at Madeira on Saturday with Lieut. Cameron on board; his health is perfectly restored. The *Congo* left Madeira the same afternoon, and is expected to arrive in England during the present week. Sir H. Rawlinson announced to the Geographical Society on Monday that it is proposed that Lieut. Cameron should appear at the next meeting of the Society, and as it is expected that the audience will be unusually large, the meeting will be held in St. James's Hall on Tuesday week, April 11.

AT the last meeting of the Geographical Society Capt. Anderson, R.E., read a paper on "The North American Boundary from the Lake of Woods to the Rocky Mountains." Capt. Anderson was chief astronomer of the North American Boundary Commission.

THE most important paper in the last (February) part of the *Bulletin* of the French Geographical Society is the first part of Dr. Nachtigal's account of his travels in Central Africa in 1869-74. M. H. Duveyrier has a paper on Lieut. Cameron's trans-African journey, and the account of Abbé David's second exploring journey in the West of China, and M. J. Codine's paper on the Portuguese discoveries on the Western African coast in 1484-8 are continued.

WE have received the first number of *La Revue Géographique Internationale*, whose proposed fortnightly appearance we announced recently. It is a well-printed quarto of sixteen pages, and starts with a very promising programme. The most notable paper is on Ancient Geographical Monuments of the Tenth and Eleventh Centuries, by M. E. Cortambert, being a notice of the principal maps of that time which have reached us. Under the heading of "Courriers de l'Extérieur" letters from correspondents in various parts of the world are published.

INTELLIGENCE from Kasan announces that the German Exploring Expedition to Western Siberia has arrived there.

THE state of Mount Vesuvius was reported by the *Daily News'* correspondent on Sunday to have been unchanged. Prof. Palmieri wrote from the Observatory on Saturday: "Smoke is still abundant. There is a reflected glare at intervals from the fire within the crater. No lava has yet made its appearance." No immediate eruption is, however, expected.

THE annual meeting of the Iron and Steel Institute was commenced on Tuesday in London, and will be concluded on Friday. The Bessemer Medal for 1875 was presented to Mr. R. F. Mushet. To-day the Council will be entertained at dinner by the Lord Mayor, at the Mansion House.

M. FRIEDEL, an able mineralogist, has been appointed Professor to the Museum of Natural History of Paris, to fill the place vacated by the retirement of M. Delafosse. It is to M. Delafosse that is due the admirable arrangement of the Gallery of Mineralogy in the Museum.

THE Lords of the Committee of Council on Education have given directions for a course of instruction in Botany to be delivered at South Kensington, commencing about the middle of June, 1876. This course will be given by Prof. Thiselton Dyer, M.A., B.Sc., &c. It will consist of a daily lecture, with practical instruction in the Laboratory, and will extend over about eight weeks. A limited number of Science Teachers, or of persons intending to become Science Teachers, will be admitted to the course free of expense. They will also receive their travelling expenses to and from London, together with a maintenance allowance of 30*s*. per week while attending the course. The hours of attendance will be from 10 A.M. to 4 or 5 P.M.

A "VICTORIA and Albert Palace Association" has just been formed. It is intended, if the consent of the Government can be obtained, to build a palace on the banks of the Thames, near Battersea Park, for the "health, recreation, and instruction of the metropolis," combining "the amusements of the Crystal Palace, the pleasures of the Albert Hall, with the instruction and benefits furnished by the Kensington Museum." It is hoped that the palace will be opened on May 1, next year.

AN International Exhibition is to be held in Paris in 1878 or 1879 at latest.

THE *Bulletin de la Société des Sciences d'Alger* for 1875 contains interesting papers on the ethnology of the Barbary races, by M. J. A. N. Perrier; and the geography, ethnography, geology, zoology, and archæology of Algeria, by Prof. Jourdan. Meteorological tables are appended, giving the observations made from three to five times daily, the barometric observations being made unfortunately with an aneroid, by which their value is much lessened.

A COURSE of Twelve Lectures on Geology, free to the public, will be delivered in the large hall of the London Middle Class School, Cowper Street, Finsbury, on Tuesday and Friday evenings, at eight o'clock, commencing April 4, by Dr. W. B. Carpenter, C.B., F.R.S.

PROF. RUBENSON has published in the *Transactions* of the Royal Academy of Sciences at Stockholm, a discussion of the rainfall of Sweden, with five plates, from the observations made at twenty-nine stations from 1860 to 1872. From this discussion we learn that Göteborg is the wettest, and Kalmar the driest station; that in advancing from S.W. to N.E. the line of maximum precipitation passes from Göteburg to near Gefle, and that as regards seasonal distribution, the maximum is assimilated to that of continental Europe, occurring generally in July and August, and the minimum to that of the eastern part of Great Britain, south of the Grampians, occurring in March and April. Two valuable tables are added, one giving the monthly means at places at which long-continued observations have been made, and the other the annual averages for the twelve decennial periods, beginning with 1751.

IN the *Bulletin International* of the Observatory of Paris, P. Denza gives an interesting notice of a comparison of the barometers at fifty-five of the Italian stations, made by him during 1870-75. The comparison was made in each case with the normal barometer of the Observatory at Moncalieri, whose error had been ascertained by comparison with the standard of the Paris Observatory through that of the Observatory at Turin.

WE have received the meteorological observations made at the Naval Hydrographic Office at Pola for January last. This number is the first of a new series giving the hourly observations of the barometer, thermometer, and anemometer, including both direction and force of wind, together with the daily and hourly averages for the month. The position of Pola on the comparatively confined basin of the Adriatic gives a peculiar value to these hourly observations.

IN the *Quarterly Journal of the Meteorological Society* appear, among other matters, a paper on the rainfall at Calcutta for the twenty-eight years ending with 1874, by Mr. R. Strachan, in which the main facts are carefully summarised and tabulated in a useful form; a description of a self-regulating atmometer, by Mr. S. H. Miller; and a short paper by Mr. William Marriott, on the reduction of barometric observations, with a table for combining the corrections for index error, temperature, and altitude. The table will facilitate the work of reduction, and is sufficiently exact for most practical purposes for which such tables are required, and may be used in preparing observations and means for the press, provided the observations and means themselves be also printed uncorrected for height.

EXPERIMENTAL RESEARCHES ON THE EFFECTS OF ELECTRICAL INDUCTION, FOR THE PURPOSE OF RECTIFYING THE THEORY COMMONLY ADOPTED[1]

THE theory generally adopted in treatises on Physics and Electricity to explain the fundamental fact of electrical induction in an insulated cylinder A B, acted on by an electrified body C, is as follows:—It is admitted that on the extremity B of the induced cylinder, that is, the extremity next to the inductor G, is found only the electricity opposite to that of the inductor; while on the rest of the same cylinder is found only electricity similar to that of the inductor. But these two opposite electricities are both supposed to be endowed with tension, consequently they ought to be divided by a neutral line. When it is wished to represent in a graphic manner the electrical distribution indicated, obtained by induction upon the cylinder A B, this is done by means of Fig. 1. In this figure A B represents the induced and insulated cylinder, C the positive inductor, *a b* the neutral line, *a p b* the negative induced electricity, which may also be called induced electricity of the first kind, and *a q b* the positive electricity, or induced electricity of the second kind.

It is obvious that the explanation commonly adopted for electric induction cannot hold for the following three reasons:—1. Because, as the two opposite electricities possess tension, they ought on that account to neutralise each other as they are present on a conducting cylinder. 2. Because in putting into communication with the earth the extremity B of the induced cylinder, upon which extremity it is admitted that the homonym of the inductor is *not* found, nevertheless that only is dissipated, while the opposite electricity, which is found on the same extremity, remains there entirely, notwithstanding its communication with the earth.

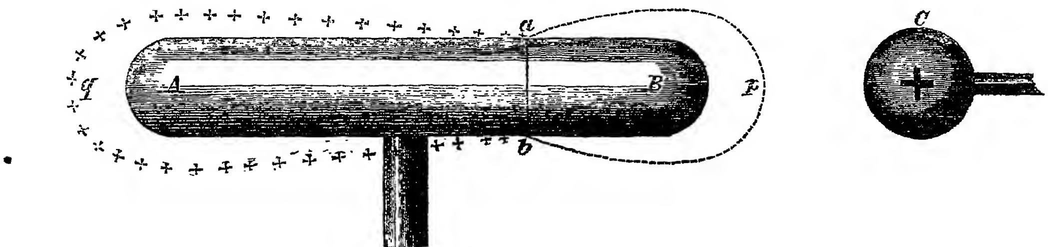


FIG. 1.

3. Because of the two kinds of electricity which coexist upon the induced insulated body, only the homonym of the inductor is dissipated by contact with the air. The experimental proofs upon which this old theory is based do not prove the facts indicated while the action of C is being exerted, contrary to what is stated in treatises on Physics. But in what follows we shall give other experimental and irrefragable proofs to demonstrate that the explanation indicated is not admissible.

Melloni[2] having discovered that the above-mentioned explanation was altogether erroneous, proposed another, which is as follows:—Upon the induced and insulated cylinder A B is found *everywhere* electricity of the same kind as that of the inductor, *i.e.*, induced electricity of the second kind; but to a much greater degree at the extremity A, furthest from the inductor and much less at the extremity B, nearest to the same inductor. As to induced electricity of the first kind, it does not possess any tension, *i.e.*, it is entirely latent (dissimulated) on the extremity B, nearest to the inductor, and proceeding from this extremity B towards the extremity A, furthest from the same inductor, it always goes on diminishing. It is for this reason that upon the induced insulated body there is a section in which the induced electricity of the first kind, entirely concealed, will be equal to that of the second kind, entirely free. Also these two opposite electricities may coexist upon the induced and insulated cylinder, without neutralising each other.

In order to represent graphically this electrical distribution, obtained by induction upon the cylinder A B, and regarded as true by Melloni, let us make use of Fig. 2. In this figure A B represents the induced and insulated cylinder, C represents the positive induction, *a b* the section of electricities equal to each other but of opposite kinds; *m, a, p, b, n*, the induced of the first kind, and *a, q, b, h* the induced electricity of the second kind, *i.e.* the homonym of the inductor.

The new theory of Melloni, the truth of which I have proved by means of the experiments afterwards described, does not complicate the explanation of the facts which depend upon it. On the contrary, it tends to present them all in a unique and invariable aspect, the only one which is really natural and conformable to observation.

In the light of this new theory we see clearly (1) why the two opposite electricities coexisting on the induced and isolated cylinder do not neutralise each other; (2) if the extremity B,

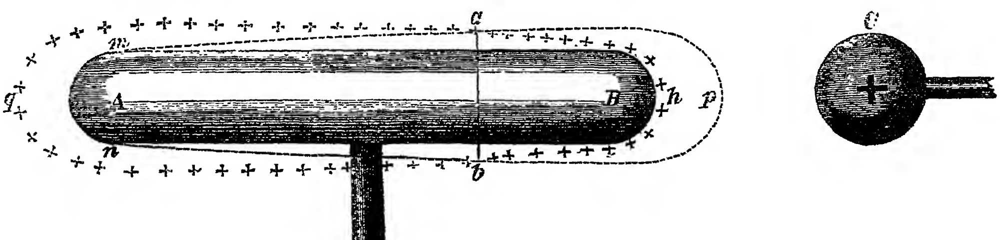

FIG. 2.

the nearest to the inductor G, is put into communication with the ground, the homonymous electricity of the inductor alone is lost, and not the opposite electricity; (3) why, of the two kinds of electricity which are found upon the insulated induced body, there is lost, by contact with the air, only the homonym of the inductor.

The cylinder A B, insulated and subjected to the influence of C, develops in a state of tension only the electricity homologous to that of the inducing body. The opposite electricity is completely latent, and becomes sensible only after the suppression of the inductive force.

When a proof-plane applied to the extremity B of the induced and insulated cylinder is subtracted from its influence, there is always seen the resultant of the two electricities which are found on the same extremity, both of them having become free, on the same proof-plane subtracted from the induction. This resultant may be either positive or negative, or even *nil*, relatively to the extremity B; but in each of these three results, we are bound to admit the pre-existence of two component electricities, opposite to each other, one completely latent, the other completely free, upon the same extremity.

If any element whatever of the section *a b* (Fig. 2) can be removed when insulated from the induction it will give a *nil* resultant.

Melloni, in the communication above referred to, confesses

[1] An Exposition of the Two Theories of Electric Induction. By M. Paul Volpicelli.
[2] "Comptes Rendus," t. 39, p. 177 (July 24, 1854).

that he is not able exactly to assign the true cause of certain facts relative to electric induction, in the phenomenon in question. We shall see in what follows, that nothing remains obscure in the theory developed by Melloni, when we reflect on the existence of what is called curvilinear induction, which was discovered by Faraday, and which is now acknowledged as a reality by all those who have kept themselves abreast of electrostatic science.

All that we have indicated in order to render clear the explanation given by Melloni of the electrostatic fact of which we have spoken, will be proved with a much greater amount of evidence by the experiments which follow. But, before describing them, it will be useful to give a brief historic sketch of the researches of different physicists as to the effect of electrical induction. The greater part of these researches are favourable to the theory of Melloni, while some are opposed to it. This theory will be acknowledged as true when it is proved that the induced electricity of the first kind does not possess any tension, or, what comes to the same thing, when it is proved that the homonym of the inductor exists also in the extremity B of the induced and insulated cylinder.

HISTORICAL.—Electrostatic induction, or electrical influence, was first observed by Canton in 1753 (Phil. Trans. vol. 48, part i., p. 350). Franklin continued his researches, but Wilke and Æpinus gave a greater development to the discovery indicated.[1] We conclude from the works of Canton that this physicist knew also the induction now called curvilinear; for he indicates several circumstances depending on the same phenomenon. The first who recognised, more than 100 years ago, that induced electricity of the first kind, that is with the sign opposite of the induction, does not possess tension, was Æpinus.[2] Subsequently Lichtenberg clearly announced that induced electricity of the first kind has no tension.[3] De Luc was also of the same opinion,[4] as also the celebrated Volta.[5] This Italian physicist[6] admitted the want of tension in the induced electricity opposite to that of the inductor, and admitted moreover that the electrical influence is exercised by means of a *partial* dissimulation of the inducing electricity, and the entire dissimulation of the induced electricity with opposite sign, a fact which is always verified. It seems that the question whether or not induced electricity of the first kind can have tension, was discussed for the first time by Lord Mahon and Volta, about 1787, to judge from what De Luc says.[7]

Among notable physicists who afterwards admitted that induced electricity of the first kind has no tension—before that doctrine was reproduced in a more developed form by Melloni, July 25, 1854—we must also reckon Fischer. This will be seen in reading Fischer's "Mechanical Physics," translated by Biot (4th ed., Paris, 1830, p. 238-242). The physicist Pfaff admitted completely the want of tension in induced electricity of the first kind.[8]

The celebrated Ohm, in a paper "On an unrecognised property of latent electricity," criticises Pfaff, and concludes that it is not true that induced electricity of the first kind has no tension.[9] Consequently if Ohm had known of the existence of the influence named curvilinear, he would, by means of his experiments, have arrived at the contrary conclusion. The curvilinear influence discovered by Faraday, was unknown also to Melloni, but, however, he did not fail to recognise the truth that the induced electricity opposite to that of the induction does not possess tension.

C. F. Mohr, a Coblentz pharmacist, criticises Pfaff, stating that in his experiments, the induced cylinder received the electricity by communication.[10] But we know that by operating on a very dry day, such communication does not take place; and yet by experimenting well, the result obtained by Pfaff is obtained, which triumphantly refutes Mohr.[11]

M. Riess gives a general *résumé* of the question in the "Repertorium der Physik" (vol. ii., p. 29; Berlin, 1838). He believes that by adopting the vertical position of the induced cylinder, instead of the horizontal position commonly adopted, we may be convinced that the pith balls, or even the gold leaves, diverge by the tension of the induced electricity—opposite to that of the inductor—which they possess. But this is not altogether true, since the *chief* cause of this divergence consists in curvilinear induction, which is not impeded in the vertical position of the inducted cylinder. Moreover, we cannot at all understand the choice of an induced cylinder placed vertically, to which, without any good reason, M. Riess has given the preference for the purpose of proving the phenomena of electrical induction, since these phenomena are always the same, and are equally well explained in an induced cylinder, whether it be vertical or horizontal. M. Riess, in his memoir "On the power of propagation of induced electricity,"[1] produces some observations against the memoir which Pfaff published in reply to that of Mohr. We shall see that the same observations are evidently overturned by my experiments, which I shall shortly describe.

In M. Riess's work "Die Lehre von der reibungse Electricitat" (Berlin, 1853, pp. 177-207), there is a very elaborate theory of electrical induction entirely opposed to that announced by Melloni, and agreeing with the old and commonly adopted theory; but the arguments and experiments of Riess are reduced to nothing by the arguments and experiments which I shall afterwards describe.

Two memoirs were published by Knochenhauer in Poggendorf's *Annalen*, in the first of which (vol. 47, p. 455, 1839) the author treats explicitly of induced electricity, and denies that it possesses any tension, at the same time also asserting that the electrical influence cannot traverse the conductors; all this agrees with our point of view. In the second memoir (Pogg. Ann., vol. 51, p. 125, 1840) he treats of the power of induction of the *Coibents*, an argument which has a close connection with electrical induction. We ought to observe here that Fischer, long before Pfaff and Knochenhauer, asserted that induced electricity had no tension. It is really extraordinary that neither Fechner nor Riess ever sought to examine the physics of Fischer in connection with the subject of electrical induction.

Knochenhauer, in a memoir in Pogg. Ann., 1843, vol. 58, p. 31), replies to Fechner, maintaining against him that induced electricity of the first kind must be regarded as entirely latent.

The physicist Petrina, in a memoir the object of which is to prove the erroneousness of the hypothesis that the electric influence can traverse a conductor,[2] shows himself favourable to the absence of tension for the induced electricity opposite to that of the inductor, and concludes that Fechner had by no means refuted the experiments of Knochenhauer which admit this absence of tension.

According to the inferences to be drawn from the memoir of Petrina above referred to, it appears that this physicist was one of the first to recognise, in 1844, curvilinear electrical induction, already demonstrated by Faraday in 1839. This phenomenon, and that of the inability of the electric influence to traverse the conductors, are both closely connected with and comprised in the fundamental phenomenon of electrical induction.[3] Faraday's researches referred to below are arranged in a series of thirty. In the eleventh of this series he speaks of his experimental researches on curvilinear induction,[4] and expresses himself as follows:—"I believe that of all the consequences which flow from the hypothesis of induction from molecule to molecule, curvilinear action is the most important of all. As the existence of such an action has been established with certainty, I do not see how the old theory of rectilinear action at a distance can be maintained, or how anyone can oppose induction from molecule to molecule." It is really astonishing that in no modern treatise on Physics or on Electricity do we find any mention of curvilinear induction, which may easily be tested by repeating the experiments of Faraday, as also the other experiments which I have published.[5] We must, however, except the treatise of De la Rive and that of M. Gavarret; in the latter there is a paragraph entitled, "Induction through dielectrics can be exerted in a curved line."

SOCIETIES AND ACADEMIES

London

Geological Society, March 8.—Pro. P. Martin Duncan, F.R.S., president, in the chair.—W. J. Chetwood Crawley, Walter Keeping, Joseph Thompson, and William Walker, were elected Fellows of the Society. The following communications were read :—1. On the influence of various substances in accelerating the precipitation of clay suspended in water, by Mr. Wm. Ramsay Principal Assistant in Glasgow University Laboratory. Communicated by Prof. Ramsay, F.R.S., V.P.G.S. The author referring to the fact that clay when suspended in water in excessively minute particles, settles more rapidly when the water contains salts in solution, noticed the opinions expressed by previous writers on the subject, and gave the results of experiments made by him, from which it would appear that the rapidity of precipitation is proportionate to the amount of heat absorbed by the salts in process of solution. By another series of experiments he found that the fluidity of the respective solutions had apparently no influence on the rapidity of deposition of the clay. He also found that clay is deposited less quickly in acid solutions than in solutions of salts, and more rapidly in a solution of caustic soda than in one of caustic potash. In solutions of common salt of different strengths he found that clay settled in the inverse order of their specific gravities. From all these results the author is inclined to attribute the varying rapidity of the settling of clay suspended in saline solutions to the varying absorption of heat by the solutions. When water containing suspended clay was heated, the rapidity of the settling of the clay was proportionate to the heat of the water. The author suggests that the increased rapidity of settlement may be due to the greater amplitude of vibration of the molecules of water when heated; the vibrations being performed in equal times, particles descending at right angles to the plane of vibration will experience less resistance from the molecules of water. A note by Prof. Ramsay, briefly indicating some of the geological bearings of these results, was appended to the paper.—2. On some Fossiliferous Cambrian Shales near Carnarvon. By Mr. J. E. Marr. Communicated by Prof. T. McKenny Hughes, F.G.S. With an Appendix, by Mr. Henry Hicks. The shales described by the author extend from about three miles S.W. of Carnarvon to Bangor, running nearly parallel to the Menai Straits. They are faulted against Lower Cambrian to the east, and disappear against a dyke on the west. The shales vary from greyish black to bluish black in colour, and are generally sandy and micaceous, but in places chiefly clayey. Fossils were obtained from three places on the banks of the Seiont, namely, near Point Seiont (where the beds are concretionary in structure), along the old tramway from Carnarvon to Wanttle, and near Peblig Bridge. The first-named locality is richest in fossils; and here there is a greenstone dyke, parallel to the bedding of the rock, and altering the shales for a distance of about four yards from the edge of the dyke. The fossils seem to indicate that the deposit belongs to the upper part of the Arenig group. Mr. Hicks pointed out that the fauna clearly showed that these beds belong to the Arieng group, many of the species being identical with those found in the upper part of that group at St. David's Shelve, and in Cumberland. The new species found by Mr. Marr are a *Caryocaris* (*C. Marrii*) and an *Æglina* (*A. Hughesii*). The other fossils were *Didymograptus indentus*, *D. bifidus*, *D. Murchisoni*, and the var. *furcillatus*. Species of *Barrandea*, *Trinucleus*, *Lingula*, *Obolella*, *Discina*, &c., and *Orthoceras caerœsiense*. The rock in its general character is extremely like that at the same horizon in the succession at St. David's Shelve, and in Cumberland, and indicates, therefore, the prevalence of similar physical conditions when deposited. The rock is such as would be formed over an even sea-bottom at some considerable distance from land and in moderate deep water. Mr. Hicks looked upon this discovery as of considerable importance, since it clearly proved the position of beds hitherto imperfectly known, and moreover shows that similar conditions prevailed over extensive areas at the time these beds were deposited. It also furnished further evidence in support of Mr. Hicks's opinion that no break occurs anywhere in the Welsh area between the Cambrian and Lower Silurian rocks.—3. On the occurrence of the Rhætic Beds near Leicester. By Mr. W. J. Harrison, Curator of the Town Museum, Leicester. The sections described by the author are shown in brick-pits in the Spinney Hills, forming the eastern boundary of the town of Leicester, and in the Crown Hill on the eastern side of a valley excavated by the Willow Brook. In the latter locality they are capped by Lower Lias. They have a slight dip to the south-east. The brick-pits show a thickness of about 30 feet of Rhætic beds above the Triassic red marl, to which their stratification is parallel. The lowest bed is a light-coloured sandy marl about 17 feet thick, traversed by three or four courses of harder, whiter stone, and containing crystals of selenite, pseudomorphs of salt, and numerous small fish-scales. A single insect wing was obtained from it. This bed extends across the valley of the Willow Brook, and forms the base of Crown Hill. Above it comes the Bone-bed, from 2 to 3 inches thick, containing numerous small teeth, bones, and scales of fishes and Saurians, including large vertebræ of *Ichthyosaurus*, ribs probably of *Plesiosaurus*, and some bones of Labyrinthodont character. Two species of *Axinus* also occur. The Bone-bed is followed by about 2½ feet of coarse black shales, overlaid by a very thin band of hard reddish sandstone, with casts of *Axinus*, and this by about 2 feet of finely laminated black shales containing *Cardium rhæticum*, *Avicula contorta*, and a Starfish (*Ophiolepis Damesii*). Above these come about 5 feet of shales with sandy partings, the lower foot rather dark and containing *Avicula contorta*, *Cardium rhæticum*, *Ostrea liassica*, and a new *Pholidophorus*; the remainder light-coloured, but with the same shells. The topmost bed in the section is a band of nodular limestone 6 inches thick. The same sequence is observed in Crown Hill. There are indications of the existence of a second nodular limestone and of beds of light-coloured clay and sand, but obscured by drift, in which, however, blocks of limestone occur with *Monotis decussata* and *Anoplophora musculoides*. The author indicates other localities where traces of the Rhætic beds are to be seen, and states that wherever the true junction of the Trias and Lias is exposed, the Rhætics appear to be invariably present. The paper also included some particulars with regard to borings in the Trias near Leicester.—4. Hæmatite in the Silurians. By Mr. J. D. Kendall. The author referred to a former paper in which he showed that direction of the hæmatite deposits in the Carboniferous Limestone of Cumberland and Lancashire is parallel to that of the meridional divisional planes, or nearly north and south; while the deposits in the Silurians are in two directions, some parallel to one set of divisional planes and some to the other. In the present paper he describes a deposit of hæmatite at Water Blean, in the parish of Millom in Cumberland, in Coniston Limestone, which appears to be altogether unlike those referred to in his former paper. The Silurians here are all conformable, with a strike about 65° N.E. and S.W. and a dip of about 80° to N.W., but their order is inverted. The hæmatite occurs in the Coniston Limestone in the form of short veins, varying in width from a few inches to 9 feet, running in the direction of the strike, and having the same dip as the limestone, their deposition having taken place along the bed-joints of the rock. The author accounts for this difference in the deposits by the fact that in the Coniston Limestone at Water Blean the bed-joints are much more persistent than the divisional planes, which are very irregular and not at all so strong and open as the bed-joints.

Zoological Society, March 21.—Dr. E. Hamilton, vice-president, in the chair.—Mr. Sclater exhibited and made remarks on a series of skins of the parrots of the Fiji Islands, obtained by Mr. E. L. Layard belonging to the collection of Lord Walden, and called special attention to a new species of the genus *Pyrrhulopsis* of Reichenbach from the Island of Taviuni, which Mr. Layard had proposed to call *P. taviunensis*.—Mr. A. G. Butler read a paper containing descriptions of some new Lepidoptera from the collection of Lieut. Howland Roberts.—A communication was read from Mr. Andrew Anderson, containing corrections of and additions to a former paper of his on the Raptorial Birds of North-Western India.—Mr. Howard Saunders read a paper on the *Stercorariinæ* or Skua Gulls, in which he revised and corrected the synonymy of several species, and traced their respective ranges so far as they were known. He considered that *Stercorarius chilensis* (Bp.), although more nearly allied to the Northern form *S. catarrhactes* than to *S. antarcticus*, was perfectly distinguishable from either by its constant rufous coloration of the underparts and axillaries; its range as at present known being restricted to the West coast of South America. The range of *Sterc. pomatorhinus* was shown to extend from S. lat. 82° N. to about 30° S., and that of Richardson's Skua, to which he restored the original, but lately disused name of *Stercorarius crepidatus* reached from 82° N. to more than 40° S., on the coast of New Zealand: *S. spinicauda* (Hardy), from the African coast, being regarded as merely this bird in winter dress.

Anthropological Institute, March 14.—Col. A. Lane Fox, president, in the chair.—Mr. Stanbridge, of Daylesford, Victoria, exhibited and presented a collection of stone implements from Australia. It consisted of some axe heads, a mounted stone spear head, some wallongs, or grinding stones, and a Yowiwi, or large flat stone, on which the Nardoo seed is ground. A large stone implement, supposed to be for digging, was also lent. The president considered this last was an unfinished tool which would have been reduced in size if finished; but it had been used apparently in its present state, one of the ends being much rubbed.—Capt. Melford Campbell, President of Nevis, exhibited some stone implements. One of these, a knife or dagger, from Honduras, is $10\frac{1}{2}$ inches long, and made of a thick flake of buff coloured chert of a fine amber hue; similar but smaller specimens from the same place are already in the Christy collection. Three polished Celts, from Turk's and Cairo Islands were shown by Capt. Campbell.—Mr. H. H. Howorth read a paper on the Samatæ, which was followed by a discussion.—Mr. H. Dillon, the Director, read a translation by Capt. R. F. Burton, of two letters from H. B. M.'s Vice-Consul at Lissa, H. Topich, on some human remains recently found in the Island of Pelagosa.

Meteorological Society, March 15.—Mr. H. S. Eaton, M.A., president, in the chair.—R. Trout Hawley Bartley, M.D., John Wuford Budd, Lieutenant-Colonel George E. Bulger, W. Brown Clegram, M. Inst. C.E., J. Sanford Dyason, John Eunson, Assoc. Inst. C.E., Thomas W. Grindle, Assoc. Inst. C.E., Major F. Bonnycastle Gritton, Junius Hardwicke, F.R.C.S., Alfred O. Walker, and the Rev. E. William Watts, M.A., were duly elected Fellows of the Society.—The following papers were then read:—On the Rhé-electromètre of Marianoni, by Robert James Mann, F.R.A.S.—On the variation of errors in hydrometers, by R. Strachan.—On the deduction of mean results from meteorological observations, by L. F. Käntz (translated from the *Repertorium für Meteorologie*, by J. S. Harding).—Summary of observations made at Stanley, Falkland Islands, during 1875, by F. E. Cobb.—Contributions to the Meteorology of West Australia, by R. H. Scott, F.R.S.

Victoria (Philosophical) Institute, March 20.—A paper was read upon the flint implements found in Brixham Cavern, in which the author, Mr. Whitley, alluded to the statements of Mr. Pengelly, whose active superintendence of the exploration of the cavern under the auspices of the Royal and Geological Societies was deserving of the warmest thanks of all geologists. Mr. Whitley complained that the Report of the Royal Society and the specimens had been allowed to lie by for fifteen years before being published and rendered accessible to the public. The consequence was, that for a long time theories having no foundation in fact had been promulgated as to these specimens, and several statements in regard to Brixham Cavern and its contents had been made in well-known geological works, which did not accord either with the recent Report of the Royal Society or Mr. Pengelly's subsequent one.

Institution of Civil Engineers, March 21.—Mr. Geo. Robert Stephenson, president, in the chair.—The paper read was descriptive of the hydraulic canal lift at Anderton, on the River Weaver, by Mr. Sidengham Duer, B.Sc., Assoc. Inst. C.E.

PARIS

Academy of Sciences, March 20.—Vice-Admiral Paris in the chair.—The following papers were read:—On the first method of Jacobi for integration of equations with partial derivatives of the first order, by M. Bertrand.—On the inferior limit which should be set to admission of steam into a steam-engine, by M. Resal.—On the storms called *foehn* in Switzerland, by M. Faye. These occur in certain parts, when a cyclone from the south-west meets the Alps; instead of showers and fall of temperature, the wind blows hotly and dryly; there is also a marked barometric depression. Around the special region the tempest produces its ordinary effects. The facts are explained by the gyratory descent of a mass of air, deprived by the mountains of the cirrhus which whirlwinds formed in the upper regions usually carry downwards. Now it is objected against M. Faye's theory of storms that a descending current should give a barometric maximum; but here, with manifest descent, there is a minimum. The barometric depression (both in the *foehn* and the ordinary storm) is a simple consequence of the gyratory movement, not the index of a strong suction excited from above on the inferior layers.—Note on an apparatus for determining the intensity and the law of development of pressures in the bore of guns with reference to the time, by M. Morin. The gaseous pressure is caused to press out a metallic jet of tin, the length of which increases with the pressure with sufficient regularity (each millimetre corresponds to about 237 kilogrammes of pressure per square centimetre). A piston is in contact with the tin cylinder, and a pencil at the end of its rod gives a tracing on a chronometric apparatus.—Determinations of nitrates and of ammonia in the water of the Seine, made on 18th March, 1876, above the bridge of Austerlitz, by M. Boussingault.—On the volume of the Seine, and the flood of 17th March, 1876, by M. Belgrand. This flood is the third highest in this century (the highest was in 1802). The Seine, in its greatest flood, gives fifty-two times more water than at low water.—On the spectrum of calcium, by Mr. Lockyer.—Actinometric measurements on the summit of Mont Blanc, by M. Violle (he will shortly give his results).—On the next hatching of winter eggs of Phylloxera; note by M. Balbiani.—Physiological action of *Amanita muscaria*, general phenomena of the poisoning; effects on organs of circulation and respiration, and disorders of calorification, by M. Alison, *inter alia*, the lowering of temperature by this substance, and the restoration to normal temperature with atropine are important.—On the means employed for education and instruction of deaf mutes, by the method of articulation, by M. Magnat.—Impossibility of the equation $x^7 + y^7 + z^7 = 0$, by M. Pepin.—On the behaviour of chronometers, by M. Rouyaux.—Geometrical solution of the problem of determining the most probable place of a ship by means of any number of straight lines of altitude greater than 2, by M. Bertot.—Influence of temperature on magnetisation, by M. Gaugain. The new facts given are briefly these:—When a steel bar in contact with a magnetic pole is gradually heated to a blue tint, the magnetism first increases, reaches a maximum, then decreases. The bar being allowed to cool while in contact, the total magnetism increases all the time, so that, when the bar has cooled to the surrounding temperature, it has much greater magnetism than before heating. The total magnetism of the bar, brought back to ordinary temperature, is greater the more the bar has been heated (at least under the temperature giving a blue tint). After breaking contact of the cooled bar for a few seconds it loses a part, but not all, of the increase of magnetism that resulted from heating.—On a rock intercalated in the gneiss of the Mantiqueira, Brazil, by M. Gorceix.—Reply to two *critiques* by M. Faye, by M. Hildebrandsson. He calls attention to three facts. It is rare that the form of isobars is circular. Synoptic charts show that the air moves spirally towards the centre of a minimum. The anterior and the posterior parts of a squall are quite different, so that after passing the centre you have a sudden change in the weather; and this is explained if the motion of the air have an upward component, for then other air unceasingly flows in from different regions. The facts cited are in opposition to M. Faye's theory.

PREECE'S TELEGRAPHY

Telegraphy. By W. A. H. Preece, C.E., Divisional Engineer, Post Office Telegraphs; and J. Sivewright, M.A., Superintendent (Engineering Department) Post Office Telegraphs. (London: Longmans, Green and Co., 1876.)

IT is with feelings of great disappointment that we lay down the latest book on Telegraphy. In a work professedly a text-book of science, one of the series that contains Clerk Maxwell's Heat, Jenkin's Electricity, Goodeve's Mechanism, and the books of Bloxam and of Miller, we certainly were not prepared to find the part of science consistently left out. We considered, in fact, that when two authors, high in their profession, undertook to supplement a recognised want in so distinguished a series of text-books, we might expect to receive from them the best and the newest information obtainable on the subject that they profess to deal with.

In the last twenty years the advances in our knowledge of the science of electricity and magnetism and of the principles of telegraphy, a branch of electrical science applied, have been very great and very important. The science and the practical application of electricity have occupied a large part of the attention of the foremost investigators in physical science. The labours of Gauss, Weber, Faraday, Joule, Helmholtz, Thomson, Maxwell, and of the celebrated British Association Committee on Standards of Electric Resistance have given to the student on the one hand and to the practical engineer on the other, a system of laws, of methods of calculation, and of experimental results as to properties of matter, that make the science of electricity perhaps the most exact of all the branches of Natural Philosophy. To ignore every exact principle from first to last of a science so well founded, and to substitute for a clear statement of these well-known principles a few sketchy paragraphs not worthy of the middle of last century, is not, in our opinion, the proper introduction to a *scientific* text-book on Telegraphy for beginners.

The authors of the work before us naturally think that "Electricity being its main theme a certain acquaintance with the elementary principles of that science must be assumed on the part of the reader." However, "the differences which exist among electricians with respect to the signification of many of the technical terms employed in connection with telegraphy render it necessary that the student at the outset should have a clear comprehension of the meaning of those which will be used in this work." Accordingly they proceed to give him a "clear" idea of "Electric quantity," "electric potential," "electric resistance" in the following way:—

"Electricity is an agent pervading terrestrial and solar space, and is as universal in its effects as are heat and light. We are cognisant of its existence when we hear the roar of thunder and see the flash of lightning, but we do not know its particular form any more than we know that of heat or that of light. The sound of the thunder and the flash of the lightning affect the ear and the eye—we hear the sound and see the light—but we do not assume the existence either of sound or of light as distinct entities or things [Remarkable statement]. We can speak of the quantity of sound caused by the explosion of a cannon or by the blowing of a penny whistle, the quantity of light emitted by a gas jet or by a farthing rushlight; the quantity of heat required to melt a pailful of ice or to solder a metal joint, without implying by the term quantity a mass or volume of anything actually present."

Notions such as these as to quantity are quite new to us. We would suggest as an examination question for science classes the comparison of the quantity of sound caused by an explosion with the quantity caused by blowing a penny whistle for a week.

Our authors proceed:—

"The term implies relative magnitude only. It is the answer to the question, 'How much?' It implies the notion of more or less. When we speak of the magnitude of electricity present or passing, we speak of its *quantity*. When we read of the church spire destroyed, of trees riven to splinters, of wires fused, or of flocks killed, the damage done is due to the electricity passing, and the amount of that damage is proportional to its magnitude or *quantity*. If we take a piece of sealing-wax, a glass rod, or an ebonite comb, and rub it against the coat-sleeve, we find it has the property of attracting feathers, straws, and other light bodies. Electricity has been excited upon its surface, and the force of attraction is found to increase with the quantity of electricity present. Conversely the force with which bodies are attracted is an indication of the quantity of electricity excited. Hence we learn that ELECTRIC QUANTITY *is the magnitude or amount of electricity present.*"

The italics and capitals in all the quotations are due to the authors.

With no further explanation or hint of anything more definite, but with a few lines, apparently meant for an explanation of the algebraic method of representing numbers by letters, the authors calmly remark:—

"The unit quantity of electricity in general use has been called a *weber*, from Weber, one of the great German philosophers."

This is absolutely everything that is given to the elementary student to enable him to understand what is meant by quantity of electricity. Not a single experiment is described, except the electrostatic experiment of rubbing a glass rod, an experiment which has very little to do with the electromagnetic unit of quantity, the weber. Not a hint is given of the electromagnetic, electro-chemical, or thermal effects of the current. We can picture to ourselves a student of lively imagination in sad perplexity as to whether the unit of current is to be expressed in terms of trees destroyed or of church-spires smashed per second, and as to the numerical relation between unit damage done and the weber. All this in the face of the beautifully simple absolute system of electrical measurement now universally adopted!

Space does not permit us to transfer to our pages in full the notions of the authors on other fundamental questions, though some of them are not less important than that which has just been noticed. A few lines of quotation must suffice:

"POTENTIAL," we learn, "*implies that function of electricity which determines its motion from one point to another.*"

We doubt whether the elementary student will obtain from this definition (?) or from the accompanying explanations, any criterion for knowing a point of high potential from a point of low potential, or any idea of how to reckon numerically the potential at a point, or even the difference of potentials between two points.

Next we learn that "RESISTANCE *implies that quality of a conductor in virtue of which it prevents more than a certain amount of work being done in a given time by a given electromotive force.*" This is prefaced by the extraordinary remark that "The transference of electricity, such as that from a charged cloud to the earth, from a rubbed glass to a rubbed comb, a signal from Europe to America, may take place in different *times;* the path between A and B offers obstruction to the passage of electricity; the medium through which it passes . . . is an obstacle to be overcome." The unit of resistance is, it is said, called the *Ohm*, from Ohm the German physicist, but the laws of Ohm are not stated, nor is the beginner even told to connect with them the idea of diminishing the current between two points by increasing the resistance between them; and with the exception of the mysterious and inaccurate reference to work done, just quoted, (and the work done in the circuit by no means presents itself directly to the attention of the beginner in electrical studies), there is nothing to afford a clue to the effect of the resistance in a given circuit. This remarkable chapter concludes as follows:—

"The nature of electricity itself is not known, nor is it necessary to the telegraphist that it should be known by him. He is only interested in its quantitative measurement and its application to practical purposes. Let him master its elementary principles, its general ideas, its properties and its conditions, and he can well afford to leave to physicists the discussion of its nature, and to mathematicians the determination of its laws."

We have no objection to these general sentiments, but we venture to think that for any one who wishes to write a book on telegraphy a moderate amount of attention to what the naturalist (we can't call him physicist) and mathematician have to impart would not be out of place.

We are far from satisfied with the chapter on batteries and with the chapters on construction; in fact our idea of what the artisan class and the beginners in science schools should expect to learn from a text-book of science in no way agrees with the ideas of the authors of this book. We cannot think that the last chapter (fifteen pages), describing the message-forms used in the British postal telegraphs, and a mass of technicalities even to the inserting of the received message in an envelope and handing it to the messenger, will be of use to anyone. And yet the dimensions allowed for the book have compelled the authors, as they tell us, "to abandon the submarine cable branch of the subject"! Similarly, "quadruplex, multiplex, and other novel systems of telegraphy have been omitted." . . . "The discussion of Ohm's laws and the apparatus depending upon them are not dealt with." Everything scientific is in fact left out.

There is a mass of technicality in the chapter on batteries, of which a host are described with their prices, &c. If space were of no consequence this would be most interesting but, for want of space, we presume, the principles of testing batteries for electromotive force and resistance are omitted. The chapters on construction contain elaborate discussions as to charring, tarring, burnetising, kyanising, boucherising poles, about the relative merits of different kinds of wood, about earth-borers, and a multitude of other things, while the principles of the parallelogram of forces practically applied to the fixing of poles by stays and struts are not mentioned. We should have thought that Mr. Preece, Mr. Sivewright, and their coadjutors leave but little choice to the artisan as to the materials and the tools to be employed in construction of telegraph lines, and that practical application of the science of dynamics to the case in hand would be of far higher value to the man who is actually engaged in stepping the poles and fixing the stays and struts, than a not very perfect description of the methods adopted for the preservation of timber. The gauge of the iron wire employed in Post Office Telegraphs is given. We are left to wonder whether in selecting wire any test as to electric resistance is applied or not; and we are not told what kind of preliminary electrical test, if any, ought to be applied. In fact, though these questions are intrinsically of extreme importance, they ought not to have been allowed utterly to displace the fundamental principles of the science of telegraph construction and of telegraphy. While they form a part of the whole subject, and they do form a very important part of it, they should have occupied a subordinate place in a book for beginners. Those who want an elementary text-book on the *science* of telegraphy, want more than a description of the practice, on their land lines, of the British Postal Telegraph department.

The chapters taken up with the instruments are, in our opinion, the best part of the book. The instruments used on land-lines are well described. Interesting information is given as to rates of working. Some of these show very wonderful results of practice. For example we learn that an experienced operator usually punches forty-five words per minute. Now a word contains 4·5 letters, and if we take it that an average letter contains, including the space that divides it from the next letter, four dots, we find that at this rate of punching 13·5 dots per second are made. If three more dots could be made per second, the strokes with the mallets would nearly cease to be heard distinct one from the other, and a deep musical note four octaves below the middle C on the pianoforte would be the result. We wonder whether this could be done were the operator to punch a few times over some sentence that he knows by heart.

We have noticed in reading the book some errors that it would be well to correct in future editions. On p. 21, damp ground is said to *abstract* a certain portion of the current. On p. 32, a battery is described as Thomson's, which is not used, and never was used, except for an experiment. Sir W. Thomson has arranged a gravity battery, very different in form from that here described, and which, being in use with his Siphon recorder, is generally known as his battery. In figures 69 and 93 the battery is represented as short-circuited by the sending key. On the whole, however, the diagrams are clear, and descriptions of the instruments well written.

MUSICAL INSTRUMENTS AT SOUTH KENSINGTON

A Descriptive Catalogue of the Musical Instruments in the South Kensington Museum. Preceded by an Essay on the History of Musical Instruments. By Carl Engel. Second Edition.

THE collection of musical instruments in the Museum at South Kensington is one of considerable and of varied interest. Consisting, as it does mainly, of the instruments employed by various nations within the last few centuries, it exemplifies the improvements in art and the gradual development of scientific principles in construction. But it includes also instruments of more remote dates such as would range within "the middle ages," and a few of prehistoric period. In the last case a similarity of musical instruments and of musical systems may be an important assistance in determining the ethnology of an extinct people, while the practice of opposite systems by neighbouring races will be a strong inference that they sprung from different stocks.

The excellent Catalogue, of which we have now a second edition, includes a prefatory essay by M. Carl Engel on the early history of musical instruments, and he has enhanced its utility by adding the scale of notes which many of the instruments would produce. This was practicable in the case of pipes, flutes, or other wind instruments from extant examples, but not with such as were stringed, because they would not remain in tune.

When a nation is found to have employed instruments constructed for the diatonic octave scale, such as the intervals of our A B C D E F G A, it is a proof that the possessors practised harmony, although it may have been but to a limited extent. The reason is that the fourth and seventh notes of such scales require different basses to the others, and would not be agreeable to the ears without the addition of such basses. On the other hand, if we find a scale of but five notes within an octave, the two omitted will be the fourth and seventh of the scale on that very account. We may in such cases conclude with safety that melody was the chief attraction to the people, and that harmony was either unknown or little appreciated.

We should bear in mind that the most ancient recorded *octave* scale of Greece and of Northern Asia and Africa is the minor; but there may have been exceptional cases of the use of the major, because the ancient Greeks had a five-note major as well as a five-note minor scale in their chromatic system. Nevertheless, it can have been but little practised by them in early ages because it was never admitted into their precepts. There is no Greek treatise upon music which includes the major scale; and yet the transition from one to the other was most easy, for whoever begins upon the third note, instead of the first, of any minor scale, will transform it into its "relative" major. These are the particular points to be borne in mind in estimating remote dates for musical instruments.

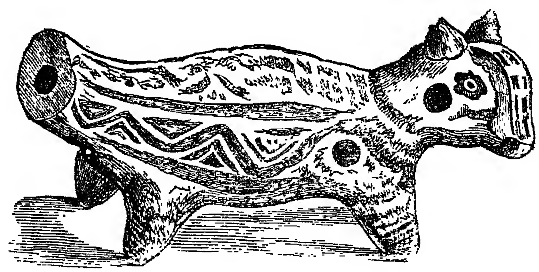

FIG. 1.—Ancient Pipe of the Chiriqui. (Centra America.)

And now to apply these principles to three of the instruments of different races discovered in Central and in South America. Among the ancient graves of the Chiriqui in Central America small pipes and whistles of pottery, which produce several sounds, have been found, of which one has six finger-holes, but in that case the notes have not been ascertained, while others have four notes, E F G A. These form the ancient Greek tetrachord, and the Greeks acquired their knowledge of music from the nations of Northern Asia and Northern Africa, especially from Egyptians, Chaldæans, and Phœnicians. Can any one of these nations have been in contact with the Chiriqui of Central America? The scale is fitted for chanted recitations rather than sufficient for music proper. F would be the chanting note of the above, with the power of ascending, for expression, to G and A, and with that of descending to the major seventh, E in preparing for a close. In this sense the notes are pure, good, and

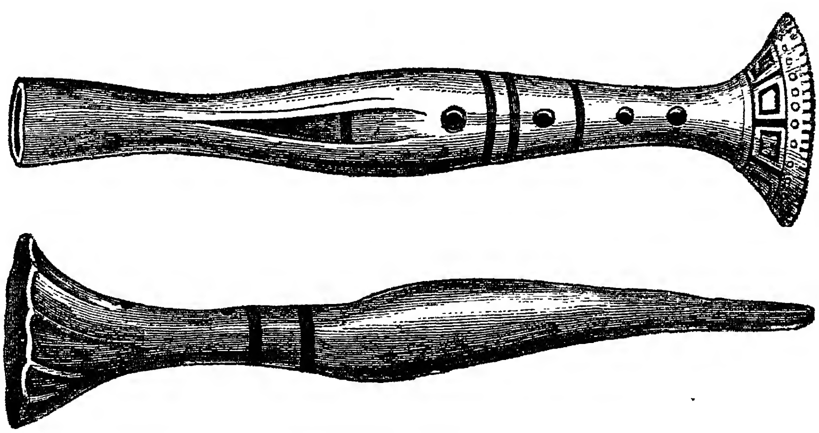

FIG. 2.—Pipes of the Aztecs.

true parts of a major scale. They are such as a correct musical ear would dictate, but they tell little as to the cultivation of music.

Upon the same page (67) M. Engel passes on to the *Pitos* (of the flageolet kind) used by the Aztecs. These are of reddish pottery, having four finger-holes, and producing five notes, including the open note of the pipe . Several examples are in the British Museum. Although Pitos vary in size they have all the same pitch of sound, says M. Engel, and are easy to blow. They have but five notes to the octave, in the major scale, and this has been popularly called "The Scotch Scale." M. Engel terms it *pentatonic*, but, if it must needs have a Greek name, we prefer *pentaphōnic*, since two of the intervals for an octave scale are of minor thirds. The points to be remarked in these Pitos are that the various lengths should have been so proportioned as to be of the same pitch, and that the scale should be major. We may say of the Aztecs, as of the Chiriqui, that the practice of harmony did not obtain among them, but the Aztecs had advanced further in the direction of melody, and had in all probability a custom of playing many pipes together in unison. They were also advanced in the manufacture of pottery. It is often convenient to suppose that a people is "indigenous," and it may have been so for many centuries, but the speculation for ethnologists is "Whence originally came the Aztecs?"

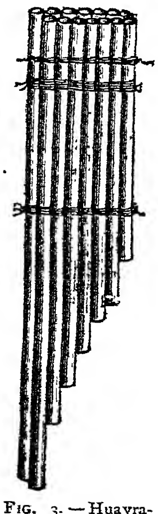

Fig. 3.—Huayra-puhura of the Inca Peruvians.

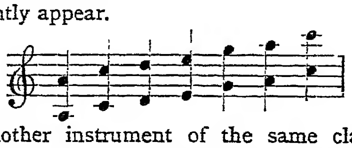
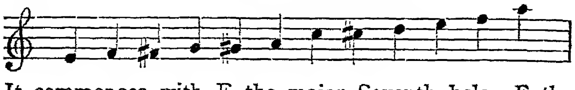
The third case is of the Inca Peruvians (p. 70). They had a Syrinx, or Pandean pipe, which played in octaves. The seven double pipes were of equal length, but the one pipe was closed at the end, and its fellow open. When M. Engel says: "The reader is probably aware that the closing of the pipe at the end *raises* its pitch an octave," it is an error in writing—he means that closing the end *lowers* its pitch an octave. The Peruvian Syrinx is *pentaphonic* in the key of C major. The scale is printed as beginning with the octaves of A, which we suspect to be a misprint for B, and the reason will pre sently appear.



Another instrument of the same class "was discovered placed over a corpse in a Peruvian tomb, and was procured by the French general Paroissien." The scale of this set of pipes, as given by M. Engel, is as follows:—



It commences with E, the major Seventh below F, the key-note, just as we suppose the preceding pipes should have been given. It then forms an ascending chromatic scale of F to the extent of an octave, excluding only the Fourth and the *minor* Seventh of the scale. The reason is evidently because those two are not good melodic intervals. They require their own basses to render them agreeable to the ear, and the instrument does not include

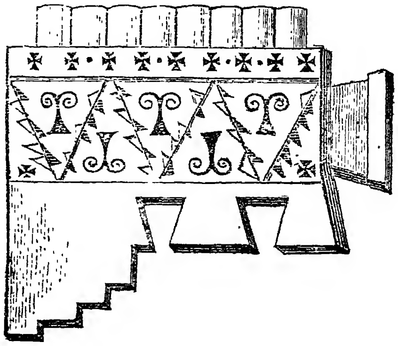


Fig. 4.—Huayra-puhura of the Inca Peruvians.

a bass. On the other hand the *major* Seventh, or semitone below the key-note, is included. It is a good melodic interval, and the French term it *la note sensible*. The only tone above the octave is A, which adds to the instrument a run over the common chord of A major.

This is a remarkable and an excellent melodic scale, which has not been duly appreciated by M. Engel. He says: "The musician is likely to speculate what could have induced the Peruvians to adopt so strange a series of intervals—indeed it seems rather arbitrary than premeditated."

A little reflection upon the intervals of the harmonic, or natural, scale would have satisfied M. Engel that these Peruvians had exceptionally correct ears for music. It is not, as he supposes, any "natural predilection for that series of intervals which may be called the pentatonic scale, *because* it contains only five different intervals in the compass of an octave" (p. 311) but, "because" the two omitted notes are unsatisfactory to the ear in unaccompanied melody. They are "irrational" intervals, and therefore they have been rejected by nations in all quarters of the globe, Scotch and Irish, Egyptians, Chinese, Malays, Peruvians, Aztecs, and others. Even Europeans, who cultivate harmony, reject the minor seventh in minor scales.

M. Engel has fulfilled a laborious duty with great industry and ability. A more intricate subject than the ever-changing names of the musical instruments of past ages could scarcely be found. It is next to impossible that it should be quite perfect. Sometimes the names of instruments were changed without any appreciable reason, and, in many cases, those names were absurdly misplaced. For instance, an Italian monochord for measuring intervals was called *tromba marina*, and was translated into English as a "trumpet marine." Dr. Burney not unnaturally assumed that it must have been a trumpet made of a shell, like the Triton's conch, but it consisted of three long pieces of wood, glued together triangularly and it had one string to be sounded by a bow. Again, as to the guitar in Spain. It had but four strings until about the sixteenth century, and then, seeing that foreign

viols had six strings, the Spaniards increased the number upon their guitars to six, and termed them vihuelas, without adopting the distinctive feature of the viol—the bow. "No es otra cosa esta guitarra sino una vihuela quitada la sexta y la prima cuerda," says Juan Bermudo, in 1555,—"This guitar is no other than a vihuela deprived of its first and sixth string"—but M. Engel has, by mistake, given the name of vihuela to the earliest guitars with four strings, as upon the portico of the church of Sant-Jago di Compostella, and others. In England, in the sixteenth century, the vihuelas were termed Spanish viols, and are so named among the musical instruments left by Henry VIII., but eventually they were reinstated in the name of *Spanish* guitars, while the old English cittern, strung with wire, and the number of strings increased from four to six (single or double), was *the* guitar of the last century. M. Engel has not recognised this change. The English had also a small instrument with four catgut strings, very like the four-stringed Spanish guitar called the gittern, or ghittern. It differed chiefly from the Spanish instrument in having a lute-shaped back instead of a flat one. M. Engel does not explain how this instrument differed from the guitar, although he has given to another its Latinised name, quinterna or guinterna.

Again, it is not in accordance with English usage to term large pieces of bamboo partially split, in order that, by shaking them, the sides may be rattled together, "castanets;" neither were castanets called *crotala* by the ancients, as M. Engel supposes. The ancient castanets were made of nut-shells, cockles, oyster-shells, or small pieces of metal, and were called *krembala*. "And beating down the limpets from the rocks," says Hermippus, "they made a noise like castanets" (κρεμβαλίζουσι). The *krotala* were maces and other large and loud rattles to be used in the worship of Cybele. Sometimes the two parts were detached and held in two hands, and sometimes they had a hinge or spring at one end, to be sounded by closing the hand suddenly so as to knock one against the other. The stork was called *crotalistria*, from the noise made by the bird in striking together the two bones of its beak.

M. Engel's history is a little at fault when he writes that "The earliest organs had only about a dozen pipes," and that "The largest, which were made about 900 years ago, had only three octaves, in which the chromatic intervals did not appear" (p. 108). This passage must be looked upon only as a prelude, intended to magnify, by contrast, the improvements which have been made in Germany and other parts of the Continent of late years. It can have no other meaning—for the organ at Winchester had 400 pipes in the tenth and eleventh centuries. It is fully described by a contemporary musician, the author of a once celebrated, but now lost, treatise, *De Tonorum Harmonia*. Two lines of extract will suffice:—

> "Sola quadringentas quae sustinet ordine musas,
> Quas manus organici temperat ingenii."
>
> Wolstan's *Life of St. Swithun*.

M. Engel makes also a mistake of from 400 to 500 years in the date of a manuscript, and, acting upon this mistake, he claims priority for Germany over England for the first use of the fiddle-bow. Strings have but a fleeting tone, unless it be sustained by friction, and the principle is so simple as to be intelligible at one glance, and therefore to be readily adopted. But the first example yet discovered is in an Anglo-Saxon MS. of the earlier half of the eleventh century, where one gleeman is playing the fiddle while another is throwing up and catching three balls in rotation (Cotton MS, Tiberius, c. vi.). This is the figure with the primitive fiddle:—

FIG. 5.—Anglo Saxon Fiddle. XIth Century. (British Museum.)

It will be seen that the shape of the body of the instrument prevents the use of the finger-board for the production of the higher notes, and to obviate this difficulty, a hole was subsequently made through the back, so that the performer's hand might have more command over the strings. In this form the Anglo-Saxon or early English name was *cruth*, Anglicè, *crowd*, a crowder and a fiddler being synonymous.

"The fiddler's crowd now squeaks aloud," &c.

FIG. 6.—Crowd. English. About the XIIIth Century.

The third stage of improvement was to diminish the size of the body, to give it indented sides so as to allow free action to the bow, and lengthen the neck, as in the

early English *citra, cetera*, or more modern *cittern*. "Fu la cetera usata prima tra gli Inglesi," says Galilei. Examples of instruments of this kind are frequent, but M. Engel startles us by exhibiting the following as an original "*German* Fiddle, IXth century, St. Blasius."

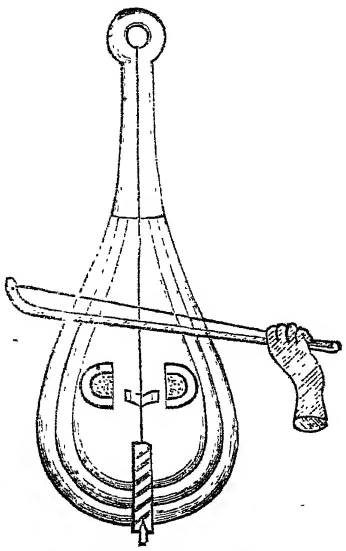

FIG. 7.—Fiddle String. XIIIth Century. (St. Blaise.)

The above is copied from Gerbert's "De Cantu et Musica Ecclesiæ," vol. ii., and is derived from a manuscript which was formerly in the monastery of St. Blaise, and which Gerbert describes as "about 500 years old!" (ex cod. San. Blas. annorum. circ. 500, p. 139) as he wrote in 1774. That would bring the date to the second half of the *thirteenth* century, instead of the eighth or ninth, as M. Engel states in his text. Moreover the plate is not intended to exhibit a fiddle, but a fiddle-*string*. It is called *lyra*, and the word is explained in two of the glossaries collected by Mr. T. Wright. A fiddle would have had more strings than one, in the thirteenth century, and the strings would have been fastened to pegs instead of a single string passed through a ring.

It will be seen from the above that the claims for Germany are put forth in the strongest light by M. Engel, and that other countries may not so readily acquiesce in them. We ourselves should raise many demurrers to his claims and conclusions, but they would apply to the prefatory essay and to the musical instruments of Europe, rather than to those of the rest of the world. While we cannot but wish that M. Engel's nationality had been less strongly developed, he is justly entitled to the credit of having ably fulfilled his commission, and of having exerted extensive research.

OUR BOOK SHELF

Notes on the Practical Chemistry of the Non-Metallic Elements and their Compounds. By William Procter, M.D., F.C.S., Lecturer on Chemistry at St. Peter's School, York. (London: Simpkin, Marshall, and Co. York: the Northern Educational Trading Co.)

THIS is a handbook on the Practical Chemistry of the Non-metallic Elements, designed to meet the requirements of pupils of Mechanics' Institutions, and of Science Classes of a similar kind. The true man of science welcomes every worthy means of spreading scientific truth, and does everything in his power to propagate that truth. He will regard with a jealous eye each work brought forward with a view of extending a knowledge of the sciences; and with a work intended for the use of a class whose opportunities of gaining knowledge are very limited, his scrutiny will be all the closer. A book written for the information of such should be couched in the simplest language, and the sense conveyed should be at once clear and comprehensive. In these respects Dr. Procter's little work cannot be termed a success. To use no stronger expression his language is frequently very vague. For example, on page 14 the author in speaking of "Chemical Affinity" says: "hence, in order that this force may be exercised by the particles coming within the sphere of each others' attraction, the substances must be in the state of liquid or gas." There can be but one way of understanding the latter part of this quotation, viz., that no chemical action can take place, unless the materials taking part in that action are each and all of them in a liquid or gaseous state. Dr. Procter is scarcely less happy in his definitions of bases, acids, &c. He says: "An acid is a compound of an electro-negative radical with hydrogen, which hydrogen it can exchange for a metal or basylous radical, and it is therefore replacable." Again, "A salt is a compound produced by the action of a base upon an acid with the displacement of the hydrogen of the latter." How can such definitions convey to the minds of pupils proper ideas of the true natures of acids and bases? Such explanations would not inappropriately be termed *indefinitions*. Chapters are devoted to chemical calculations, and chemical manipulations, and here doubtless the readers will find many useful hints for their guidance in the preparation of their apparatus, &c. In the body of the book Dr. Procter treats of the non-metallic elements, giving the ordinary methods of preparing them, and their compounds, and illustrating the characteristics of each by interesting and instructive experiments. A few pages devoted to the chemistry of water, qualitative analysis of gases, and the preparation of ordinary reagents, complete a book, which, designed for a good purpose, and containing much useful information, at the same time shows want of care in compilation, and also lacks lucidity. Printer's errors are much too numerous.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

The Use of the Words "Weight" and "Mass"

Nothing could illustrate more forcibly the necessity of rendering definite the meaning of some of our present fundamental terms in connection with the science of dynamics, than a comparison of my letter to you on this subject (vol. xiii. p. 325) with the letter of Mr. Stoney, in reply to it (vol. xiii. p. 385), and that of Mr. Walker who follows Mr. Stoney.

When we who call ourselves teachers do not agree as to the signification of the most elementary terms we use, it is not to be wondered at, if those who come to learn should fail to attain clear ideas on a part of the science, where such confusion of nomenclature prevails.

My letter to you was for the purpose of pointing out an ambiguity of language, and of suggesting, in order to get rid of this ambiguity, not an alteration of the meaning of any word whatever, but a very simple *restriction* in the use of words, and the bringing into more frequent employment a very valuable old word—*gravity*—which has been lying ready for use but left almost idle. Mr. Stoney admits the ambiguity to be a very real one.

Mr. Stoney, however, says: "I fear Mr. Bottomley's remedy,

if adopted, would introduce quite as serious, perhaps a more serious ambiguity. Gravity is an acceleration. When we say that gravity is less in a balloon, or in a mine, than at the surface of the earth, or greater at Glasgow than at Manchester, we are speaking of alterations of g—the acceleration due to the earth's attraction; and it would create confusion to employ this word to designate forces also."

Now I do not think that the use of the word gravity as an acceleration is at all common. On the contrary, I have looked into all the books at my command and I cannot find any support whatever for such a use of the word. Every one is accustomed to speak of the "force of gravity." To speak of the force of an acceleration would be a complete anomaly.

All the dictionaries that I have seen support my view that gravity means force, and does not mean acceleration. Take, for example, a good modern book, the Imperial Dictionary. There I find—Gravity (Lat. *gravitas* from *gravis*, heavy). 1. Weight, heaviness. 2. In philosophy—that force by which bodies tend or are pressed, or drawn towards the centre of the earth—and so on; showing that gravity always means force, though it has various shades of meaning in its occasional applications.

Chambers' Encyclopedia says that the *force* which causes bodies to fall towards the earth is termed *gravity*. The article goes on to speak of the force of gravity at the earth, at various heights above the earth, and at the moon. Acceleration is nowhere mentioned as a meaning of the word gravity.

Even if it could be shown that a few people have so far departed from the original etymological sense and prevailing use of the word gravity, as to employ it for an acceleration instead of for a force, this would only prove that the word is, to that limited extent, subject to ambiguity at present. The course that I advocated was to avoid ambiguity by employing the word *gravity*, used in its most common, and most authoritative sense, instead of a thoroughly ambiguous word *weight*, in certain cases where misapprehension from the use of the latter word is likely to occur.

It seems to me that Mr. Stoney and Mr. Walker have been led away by thinking of the letter g, rather than of the important question at issue. The letter g stands for a *number*. One way of specifying what number g stands for, is to say that it is the numerical expression for the acceleration *due to gravity*, that is, the acceleration due to the force of gravity acting on a falling mass. But this is simply because g is the number which represents the force in Gaussian units on unit mass, and because the force of attraction on any body is proportional to the mass of the body. *The latter is an experimentally discovered law.* To say with Mr. Walker that "the symbol 'g' is gravity," and with Mr. Stoney that "gravity is an acceleration," seem to me expressions equally elliptic on the one hand, and, without full explanation, misleading on the other.

If Mr. Stoney offers any method of getting rid of the ambiguity better than that already introduced, others will gladly adopt it. As to Mr. Walker's proposal to confine the use of the word "weight" to mean force, my former letter was partly for the purpose of showing this to be impossible. The act of parliament, regulating weights and measures, settles that matter. Mr. Stoney's letter forms, also, a sufficient answer to Mr. Walker's proposal.

University, Glasgow, March 27 J. T. BOTTOMLEY

P.S.—Allow me to thank Mr. Barrett for his information as to the earliest use of spring balances for kilodynes.

If Mr. Walker is serious in proposing to use *vires* for British kinetic units of force, he ought to avoid *centivires* and *millivires* for 100 vires and 1,000 vires respectively. These would be utterly incompatible with the use of the prefixes *centi*, *hekto* and *milli*, *kilo* in the now established metrical system.

Birds as Astronomical Objects

THE following note which appears in the last number of *Stray Feathers* (iii. p. 419), seems to deserve more attention from astronomers than it will perhaps receive unless published where it will meet the eyes of others than Indian ornithologists. I beg leave, therefore, to ask that it may be reproduced in NATURE.

"Looking at the sun this morning, I saw birds very frequently pass the disc. Some were in focus with the sun itself, the wings being quite sharp against the disc, and must have been several miles high, but some were much nearer, and I estimate their distance from me at about two miles by the focus required to see them. These last must, however, have been quite a mile above the earth's surface, and of course many were a great deal higher.

"I suppose they were Kites, but the appearance there was rather as though the wings were long and narrow like those of Swallows, whereas I should have expected the points to be blunted by the irradiation.

"The estimated distance between the tips might be a couple of feet.

"Possibly this may interest some of the readers of *Stray Feathers*. "J. TENNANT, R.E.

"Roorkee, 23rd September, 1875."

On this note the editor of *Stray Feathers*, Mr. A. O. Hume, remarks:—

"Many of those birds must have been quite invisible to the naked eye. I have no doubt that Vultures, Kites, and Eagles often soar for hours at heights at which they are thus invisible to us, though we and our doings are quite within the grasp of their far-seeing gaze. This would help to account for the marvellous manner in which, when an animal is killed in the plains, an apparently speckless sky becomes in an incredibly short space of time crowded with 'an heavenly host.'"

We know so little with respect to the height at which birds do or can fly, that I am sure all ornithologists would gladly avail themselves of any observations on the part of helioscopists or other astronomers that would bear upon the matter, and I may add that perhaps the evidence they could offer might be of importance as regards the migration of birds. In Mr. Hume's remarks I entirely concur. ALFRED NEWTON

Magdalene College, Cambridge, March 25

How Typhoid Fever is Spread

THE case in which the poison of typhoid fever mixed with drinking water was transmitted through nearly a mile of porous earth, and which was mentioned in the abstract of my discourse to the Fellows of the Chemical Society (NATURE, vol. xiii., p. 331), is fully described (in German) in the 6th Report of the Rivers' Commission on the Domestic Water Supply of Great Britain. It will shortly appear, in English, in the Monthly Journal of the Chemical Society. Meanwhile perhaps I may be allowed to trespass upon your space with the following remarks:—The outbreak of typhoid fever occurred at the village of Lausen, near Basel, in Switzerland, and it was exhaustively investigated by Dr. A. Hägler of Basel, who has given a full account of it in the "Deutsches Archiv. f. Klin. Med. xi." The source of the poison was traced to an isolated farmhouse on the opposite side of a mountain ridge, where an imported case of typhoid, followed by two others, occurred shortly before the outbreak. A brook which ran past this house received the dejections of the patients and their linen was washed in it. This brook was employed for the irrigation of some meadows near the farm-house, and the effluent water filtered through the intervening mountain to a spring used in all the houses of Lausen, except six which were supplied with water from private wells. In these six houses no case of fever occurred, but scarcely one of the others escaped. No less than 130 people, or seventeen per cent. of the whole population, were attacked, besides fourteen children, who received the infection whilst at home for their holidays, and afterwards sickened on their return to school.

The passage of water from the irrigated meadows to the spring at Lausen was proved by dissolving in it, at the meadows, 18 cwt. of common salt, and then observing the rapid increase of chlorine in the spring water; but the most important and interesting experiment consisted in mixing uniformly with the water 50 cwt. of flour, not a trace of which made its way to the spring, thus showing that the water was *filtered* through the intervening earth and did not pass by an underground channel.

These are the main features of the case, but there are other interesting details showing how carefully the investigation was conducted; for these, however, I must refer Mr. Mitchell Wilson to the works above cited. It affords a clear warning of the risk which attends the use, for dietetic purposes, of water to which even so-called *purified* sewage gains access; notwithstanding that, as at Lausen, such water may have been used with impunity for years, until the moment when the sewage became infected with typhoid poison.

E. FRANKLAND

Lisbon Magnetic Observations

MR. DE BRITO CAPELLO, Director of the Lisbon Magnetic Observatory, having addressed to me several interesting results having reference to the notice of his observations which appeared in NATURE, vol. xiii. p. 301, I am anxious to communicate them to your readers.

With reference to the movement of the declination magnet from 8 A.M. to 2 P.M. Mr. Capello gives me the following mean values for each year from 1858 to 1875:—

1858	8'.74	1867	6'.15
1859	10.54	1868	7.17
1860	10.11	1869	8.42
1861	9.00	1870	10.83
1862	7.84	1871	10.60
1863	7.65	1872	9.45
1864	6.94	1873	8.22
1865	6.61	1874	7.23
1866	6.19	1875	6.09

These quantities, Mr. Capello remarks, show the maxima 1859·8 and 1870·9, and the minimum 1867·1, agreeing very nearly with the epochs of maximum and minimum sun-spots.

It also appears as if the minimum had been reached again last year, the mean oscillation (6'·09) being less than in 1867. This agrees with the conclusion derived by me from the Trevandrum observations, and communicated to the French Academy of Sciences last year. Dr. R. Wolf had previously (as I now find[1]) concluded from his sun-spot observations that the minimum would probably appear in 1875–6; and he considers we have now one of the short periods, which his tables of sun-spots show may be expected every 80–90 years. My own conclusion to the same effect (that we have now a short period) was founded on a consideration of the magnetic observations. The last short period was that from the maximum 1829·7 (shown by Arago's observations) to that of 1837·5 (shown by Gauss's observations), an interval of rather less than eight years. If we may take 1875·5 as the epoch of the present minimum, then the interval from the last is nearly nine years. As the interval from the minimum of Arago (1824·2) to the next was nearly 9·2 years, we find a space of nearly forty-two years from the last short period to this one. Should this hold for the next maximum it will occur about 1879·0.

Mr. Capello has obtained the interesting result that the curve showing the mean diurnal disturbance of the vertical magnetic force is the exact inverse of that for the mean diurnal disturbance of declination at Lisbon; a movement of the north pole of the declination magnet towards the west corresponding to one downwards of the south pole of the balance needle. It appears also that the difference of sign in the temperature coefficient for the balance magnet due to changes of the compensation bar from brass to zinc and zinc to brass, on which a remark was made in NATURE, vol. xiii. p. 302, does not affect the results for the diurnal variation, each year giving the same mean law of a minimum vertical force between 11 A.M. and noon, and a maximum near 5 P.M. whatever the sign of the temperature coefficient. It appears also that the results at Lisbon are confirmed by those obtained at Coimbra, ninety miles to the north.

JOHN ALLAN BROUN

[1] "Astronomische Mittheilungen," 38, p. 378, July 1875.

The Early History of Continued Fractions

THE reviewer in NATURE, (vol. xiii., p. 304), very properly points out that the first mathematician who used continued fractions was Cataldi, and not Lord Brounker, as is still often stated.

To this fact I drew attention in a pamphlet, published in 1874, not then knowing that De Morgan had done the same many years ago. There is, however, in connection with the same subject, another historical fact almost equally interesting, which few in this country seem to be aware of, and which therefore it may be desirable to bring before your readers.

Daniel Schwenter, a professor at Altdorf, in the first quarter of the seventeenth century, made use of the present well-known process for expressing the ratio of two integers as a continued fraction, and calculated the convergent, exactly in the mode at present followed. He does not indeed seem to have written as we now do the actual continued fraction obtained in any case, but the process of repeated division, and the mode of finding the convergents were most fully described and exemplified by him.[1]

The following, therefore, seems to be, in few words, the early history of continued fractions:—

1. Cataldi published, in 1613, his discovery that the square root of an integer can be expressed as an interminate continued fraction, *e.g.*,

$$\sqrt{18} = 4 + \cfrac{2}{8 + \cfrac{2}{8 + \cfrac{2}{8 + \cdots}}}$$

2. Schwenter, almost certainly without knowledge of what Cataldi had done, published in 1636 the mode of changing an ordinary fraction into a continued fraction with unit-numerators, and of calculating therefrom convergents to the given fraction, *e.g.*,

$$\frac{117}{233} = \cfrac{1}{1 + \cfrac{1}{3 + \cfrac{1}{6 + \cfrac{1}{4 + \cfrac{1}{2}}}}}\,;$$

3. Brounker, very probably in ignorance of what had been done by Cataldi and Schwenter, made the discovery that

$$\frac{\pi}{2} = \cfrac{1}{1 + \cfrac{1}{2 + \cfrac{4}{2 + \cfrac{9}{2 + \cdots}}}}$$

which was published by Wallis in 1655 ("Arithmetica Infinitorum" p. 181), along with a tolerably complete theory of continued fractions in general.

The necessary details bearing on these three main facts will be found in a painstaking work by Prof. Favaro, "Notizie Storiche sulle Frazioni Continue," Roma, 1875, or in shorter form, in a school "programme" by Dr. Günther, "Beiträge zur Erfindungsgeschichte der Kettenbrücke," 1872.

That Cataldi, Schwenter, and Brounker, starting from totally different points should all light on the continued fraction form, and that it should be twice (perhaps nearly thrice) lost, are certainly strange facts, forming a curious chapter in the history of scientific discovery.

The Dry River-beds of the Riviera

MR. R. E. BARTLETT (NATURE, vol. xiii. p. 406) asks for some theory to account for the existence of the broad stony river-beds of Piedmont. He instances the Paglione at Nice, which is indeed the merest rudiment of a river for the greater part of the year. But if Mr. Bartlett will wait, not so much for the snows on the Maritime Alps to be melted, as for the rainy weeks of autumn to come again,

> Quum fera diluvies quietos
> Irritat amnes,

he will see that that now despicable river annually flows with a vehemence and a volume worthy of its size. Many a dry and insignificant torrent-bed in the neighbourhood of Nice swells during the rainy season to a torrent indeed; the thoroughness with which they then drain the adjacent slopes is amply sufficient to explain their existence and their appearance when their "occupation's gone."

The Flame of Common Salt

HAVING been much interested in the progress of the investigations concerning the blue flame of common salt when thrown into a coal fire, I made the following experiments, by which I came to the conclusion that the origin of the blue flame is due to the presence of copper, which occurs in nearly every coal as an ingredient of the pyrites.

According to "Bercelius," by agency of the blow-pipe, small

traces of chlorine can be discovered by dissolving at first a larger quantity of oxide of copper in a bead of microcosmic salt; if, then, any substance containing chlorine be brought in contact with the bead on the point of the blue jet, the blue flame of the blow-pipe is coloured azure blue; the same colour is even exhibited when chloride of sodium and oxide of copper are heated in the bead; the yellow flame of the sodium is scarcely visible, and does not conceal the azure blue flame.

In making the above experiment, I immediately suspected that the blue light imparted to the coal corresponds with the light of the microcosmic bead, the chlorine of the salt combines with the copper, which burns with the azure blue flame.

To convince myself that the blue colour is not due to any other cause, I took a charcoal fire free of copper, and threw salt into it; the salt gave a slightly yellow flame of sodium, and not the minutest trace of a blue flame could be discovered, though large quantities of salt were used, but on throwing the slightest quantity of oxide of copper on to the charcoal, the azure blue colour occurred instantly.

The following chlorides, HCl, KCl, NH_4Cl, $BaCl_2$, $CaCl_2$ which I had at my disposal, exhibited more or less a blue colour when cast into a coal fire.

Middleton St. George

OUR ASTRONOMICAL COLUMN

DOUBLE STARS.—Baron Dembowski communicates to the *Astronomische Nachrichten*, Nos. 2,076–2081, his later measures of double-stars, amongst which is a considerable number of well known binaries. The measures are given in a slightly modified form from that adopted in most of the Baron's previous important communications, which commenced in vol. 62 of the above periodical.

For the sake of facilitating a comparison with the best-determined orbits of revolving double-stars, we extract a few of the most recent Gallarate epochs or means of the year's measures:—

Name of Star.	Year.	Position.	Distance.	Position (c – o).	Distance (c – o).
		°	"	°	"
Castor ...	... 1875·25	235·03	5·54	+ 0·94	+ 0·39
ζ Cancri ...	... 1875·14	130·94	0·74	+ 0·88	– 0·05
ξ Ursæ Maj.	.. 1875·27	317·56	1·09	+ 6·44	– 0·13
γ Virginis...	... 1874·93	159·35	4·77	+ 0·80	0·00
ξ Bootis ...	... 1874·89	286·32	4·54	+ 1·12	+ 1·02
η Coronæ Bor....	1875·41	66·69	0·86	– 3·13	+ 0·13
ξ Scorpii ...	... 1874·96	68·97	7·12	– 1·80	+ 0·06
ζ Herculis	... 1875·52	149·09	1·41	– 1·20	– 0·09
70 Ophiuchi	... 1875·52	83·72	3·48	+ 3·11	+ 0·85
δ Cygni ...	... 1875·02	335·26	1·60	– 1·13	– 0·14
Σ 3062 ...	... 1875·67	292·17	1·47	– 4·62	+ 0·14

The orbits with which the above comparisons have been made are by the following calculators; the periods of revolution are added.

Castor	Thiele	996·85	years.
ζ Cancri	O. Struve	62·4	"
ξ Ursæ Majoris ...	Hind	60·68	"
γ Virginis	Thiele	185·01	"
ξ Bootis	Hind	168·9	"
η Coronæ Bor. ...	Wijkander	41·58	"
ξ Scorpii	Thiele	49·05	"
ζ Herculis	Dunér	34·22	"
70 Ophiuchi ...	Schur	94·37	"
δ Cygni	Behrmann	415·1	"
Σ 3062...	Schur	112·64	"

Comparisons are omitted in the cases of several binaries, the orbits of which have been worked up to about present time, principally by Dr. Doberck, of Markree Observatory. Mr. W. Plummer's orbit of ζ Cancri gives the angle 15° greater than the measures, the distance nearly agreeing. The orbit of ξ Ursæ Majoris by Dr. Ball, of Dunsink Observatory, Dublin, is not available as printed in the "Monthly Notices" of the Royal Astronomical Society, the excentricity being omitted, and the same element has escaped also in Dr. Doberck's orbit of σ Coronæ Borealis.

THE EQUATOR OF MARS.—Sir W. Herschel's determination of the position of the plane of the equator of this planet, from observations made in the autumn of 1783, was communicated to the Royal Society in December of the same year. He found for the inclination of the axis to the orbit, 61° 18′, and therefore for the obliquity on the globe of Mars, 28° 42′; the inclination of the axis to the ecliptic, 59° 42′, the north pole being directed in 1783 to longitude 347° 47′. From these figures we deduce for the ascending node of the equator of Mars upon that of the earth (N) 48° 9′, and its inclination thereto (I) 41° 27′.

Olbers, from the observations of Schroeter and Harding, on the south polar spot upon Mars in October and November, 1798, found for the longitude of this pole 172° 54′·7, and the latitude 60° 33′·2, and hence we have for the ascending node of the equator on the orbit, 84° 54′, and for the obliquity on Mars, 27° 57′; the ascending node of the equator of Mars upon the terrestrial equator 50° 29′, and the inclination 39° 14′.

But the determination which has been generally relied upon as the best yet available is that made by Dr. Oudemanns, now director of the Observatory at Batavia, from measures by Bessel with the Königsberg heliometer, 1833–37. For about 1834·0 he found the longitude of the north pole of Mars 349° 1′, and its latitude 61° 9′. The node of the orbit of the planet in the ecliptic being at this time in 48° 16′, and the inclination 1° 51′, we have for the ascending node of the equator of Mars on his orbit, 80° 50′, and for the obliquity of the Martial ecliptic, 27° 16′, and therefore for the ascending node of the equator of Mars upon the terrestrial equator, 47° 34′, and its inclination, 39° 56′. Assuming these figures to apply to 1834·0, we get for 1877—

$$N = 47° 55' \qquad I = 39° 46'.$$

A SOUTHERN COMET (?).—The *Wanganui Herald* (N.Z.), of January 20, says:—"What appeared to be a small comet was visible in the south, in the constellation of Argo Navis, for about two hours last night, the rising moon rendering it invisible. It was very small, and appeared to be rapidly moving towards the east." The summary number of the *Melbourne Argus* of January 26 has no reference to the visibility of a comet, and the above notice at present requires confirmation.

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA[1]

VI.

THE order *Cetacea* is one of peculiar interest, having many specialities of structure, and being sharply defined from all other groups, with no outlying or doubtful forms at present known. Being purely aquatic animals, and all of considerable size, their remains are more readily preserved than those of some other orders. None, however, have been met with in the well-explored deposits of the cretaceous seas, or indeed in any European strata (with the doubtful exception of the cervical vertebræ of *Palæocetus* from Ely), earlier than the Miocene. Abundant remains are, however, found in various Miocene and Pliocene marine beds, notably at Antwerp, in many parts of France, Germany, especially the Vienna basin, Italy, and South Russia. They are also found, though in a less perfect condition, in the crags of the east of England. In the Eocene deposits of the eastern states of America, the strange and gigantic Zeuglodons occupy the place of the ordinary Cetacea, which occur in the Miocene and later ages.

Among the existing members of the order there are two very distinct types, the toothed whales or *Odontocetes*,

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.) Continued from p. 410.

and the baleen whales or *Mysticetes*, and none of the known extinct forms present true transitional or intermediate characters; but it must be remembered that even such remains as have been already collected have not yet been thoroughly worked out. The Mysticetes appear, at first sight, the most specialised and aberrant, in the absence of teeth, in the presence of whalebone or baleen, in the form and size of the mouth; but as we see in other groups, dental characters and all such as relate to the prehension of food generally, are essentially adaptive, and consequently plastic or prone to variation, and hence cannot well be relied upon as tests of affinity. In another character, also adaptive, the laxity of the connection of the ribs with the vertebral column and with the sternum, and the reduction of that bone in size, allowing great freedom of expansion of the thoracic cavity, for prolonged immersion beneath the water, the Mysticetes have passed beyond the Odontocetes in specialisation. On the other hand, the great symmetry of the skull, the more anterior position of the nares, and their double external orifice, the form of the nasal bones, the presence of a distinctly developed olfactory organ, the mode of attachment of the periotic bone to the cranium, the presence of a cæcum, and the regular arrangement of the alimentary canal, the more normal characters of the manus and the better development of the muscles attached to it, and the presence (in many species at least) of parts representing a hind limb, all show less deviation from the general mammalian type than is presented by the Odontocetes. Taking all their structural characters into consideration, as well as what we know of their past history, it does not appear that we can consider either type to have been derived from the other, at all events in the form in which we see it now, but must rather view them as parallel groups.

Among the Mysticetes, in the especially distinguishing characters of the division, the *Balænopteræ* are less specialised than the *Balænæ*, which in the greater size of the head, the length and compression of the rostrum, the development of the baleen, and the shortness of the cervical region, are exaggerated types of the former, and yet they retain more fully some primitive characters, as the better development of the hind limb, the pentadactylous manus, and the absence of a dorsal fin. Both forms are found distinct in a fossil state as far back as the early Pliocene, but generally represented by smaller species than those now existing. The Mysticetes of the Miocene seas were, as far as we know at present, only *Balænopteræ*, some of which (*Cetotherium*, Brandt) were, in the elongated flattened form of the nasal bones, the greater distance between the occipital and frontal bones at the top of the head, and the greater length of the cervical vertebræ more generalised than those now existing. In the form of the mandible they are considered by Van Beneden to present more approximation to the Cetodonts.

Among the toothed whales, the earliest known form, the *Zeuglodon*, was far the most aberrant, approaching in the structure of its skull and teeth to a more generalised but very low carnivorous type. In smallness of cerebral cavity, compared to the mouth and other parts of the skull, it is as far below all other known cetaceans, as the singular *Arctocyon primævus* is below all carnivores. One could quite imagine that the skull of a very degraded seal would present many features in common with Zeuglodon, and this is the only near link we seem to possess between the Cetacea and the rest of the animal world. All the resemblances which some naturalists have seen between the skull of Zeuglodon and the Sirenia are purely superficial and imaginary. The forward position of the narial aperture and the length and flatness of the nasal bones which this animal possesses in common with (though to a greater extent than) the Mysticetes, we may suppose to be common primitive cetacean characters, though completely lost in all other known Odontocetes. Even the Squalodons, which in dental characters so much resemble the Zeuglodons as to have been placed in the same genus by some zoologists, agree in their essential cranial characters with the ordinary dolphins. They are, in fact, dolphins with double-rooted molar teeth, peculiar to the Miocene formations of Europe and America. Among existing dolphins, *Platanista* has been considered to conform most to the general type of mammalian structure. It is therefore interesting to find a similar form (*Champsodelphis*) well represented among the earliest fossil remains of Cetaceans in Europe, and others abundant in North America. Apart from these the greater number of toothed whales range themselves under the two principal heads of *Ziphioids* or *Physeteroids*, and *Delphinoids*. The former are an ancient group, of which the remains are exceedingly numerous in the Antwerp and Norwich crags, and of which the existing sperm whale is a highly modified and specialised form. Among the latter, *Delphinus* and its various modifications may be regarded as the dominating type of Cetaceans at the present day, abundant in slightly differentiated species, and abundant in individuals. They are in this respect to the rest of the order, much as the hollow-horned ruminants are to the Ungulates.

It seems in vain at present to speculate upon the origin of the Cetacea. They present no marks of closer affinity to the lower classes of Vertebrates than do the rest of their own class. Indeed, in all that characteristically distinguishes a Mammal from the oviparous Vertebrates, especially in the nervous and reproductive systems, they are far above many other groups of the class. There is no existing order of land mammals to which they can be said to be decidedly and unquestionably allied. Their agreement with the *Sirenia* is mainly in modifications of structure adapted for a somewhat similar mode of existence, while in many essentials the difference between them is as wide as that between any other two orders. Taking into consideration many of their habits, and their food, and bearing *Zeuglodon* in mind, a relationship to the Carnivora through the seals seems indicated; but if the mode of development has the weight many modern zoologists are disposed to assign to it, their affinities would be rather with the Ungulates, an order from which, on other grounds, they are far removed.

(*To be continued.*)

ON REPULSION RESULTING FROM RADIATION.—PART IV.[1]

In this paper the author describes experiments on the repulsion produced by the different rays of the solar spectrum. The apparatus employed is a horizontal beam suspended by a glass fibre, and having square pieces of pith at each end coated with lampblack. The whole is fitted up and hermetically sealed in glass, and connected with an improved mercury-pump. In front of the square of pith at one end a quartz window is cemented to the apparatus; and the movements of the beam, when radiation falls on the pith, are observed by a reflected ray of light on a millimetre-scale. The apparatus was fitted up in a room specially devoted to it, and was protected on all sides, except where the rays of light had to pass, with cotton-wool and large bottles of water. A heliostat reflected in a constant direction a beam of sunlight, which was received on an appropriate arrangement of slit, lenses, and prisms for projecting a pure spectrum. Results were obtained in the months of July, August, and September; and they are given in the paper graphically as a curve, the maximum being in the ultra-red, and the minimum in the ultra-violet. Taking the maximum at

[1] Abstract of a paper read befor the Royal Society, Feb. 10, 1876, by William Crookes, F.R.S., &c.

100, the following are the mechanical values of the different colours of the spectrum :—

Ultra-red	100
Extreme red	85
Red	73
Orange	66
Yellow	57
Green	41
Blue	22
Indigo	8½
Violet	6
Ultra-violet	5

A comparison of these figures with those usually given in text-books to represent the distribution of heat in the spectrum is a sufficient proof that the mechanical action of radiation is as much a function of the luminous rays as it is of the dark heat-rays.

The author discusses the question, "Is the effect due to heat or to light?" There is no real difference between heat and light; all we can take account of is difference of wave-length; and a ray of a definite refrangibility cannot be split up into two rays, one being heat and one light. Take, for instance, a ray of definite refrangibility in the red. Falling on a thermometer it shows the action of heat, on a thermopile it produces an electric current, to the eye it appears as light and colour, on a photographic plate it causes chemical action, and on the suspended pith it causes motion. But all these actions are inseparable attributes of the ray of that particular wave-length, and are not evidence of separate identities.

The author enters into some theoretical explanations of the action of the different parts of the spectrum, but these cannot well be given in abstract.

An experiment is described by which sunlight was filtered through alum, glass, and water screens, so as to cut off the whole of the ultra-red or dark-heat rays. The ray of light which was thus freed from dark heat was allowed to fall on the pith surface of the torsion-apparatus, when it produced a deflection of 105°. On interposing a solution of iodine in disulphide of carbon the deflection fell to 2°, showing that the previous action was almost entirely due to *light*. With a candle tried under the same circumstances, the light filtered from dark heat produced a deflection of 37°, which was reduced to 5° by interposing the opaque solution of iodine.

In order to obtain comparative results among discs of pith coated with lampblack and with other substances, a torsion-apparatus was constructed in which two or more discs could be exposed one after the other to a standard light. One disc always being lampblacked pith, the other discs could be changed so as to get comparisons of action. If the action of radiation from a candle on the lampblacked disc be taken as 100, the following are the proportions obtained :—

On Lampblacked pith	100
Iodide of palladium	87·3
Precipitated silver	56
Amorphous phosphorus	40
Sulphate of baryta	37
Milk of sulphur	31
Red oxide of iron	28
Scarlet iodide of mercury and copper ...	22
Lampblacked silver	18
White pith	18
Carbonate of lead	13
Rock-salt	6·5
Glass	6·5

In consequence of some experiments tried by Professors Tait and Dewar, and published in NATURE, vol. xii. p. 217, the author fitted up a very sensitive apparatus for the purpose of carefully examining the action of radiation on alum, rock-salt, and glass. The source of radiation was a candle. Perfectly transparent and highly polished plates of the same size were used, and the deflection was made evident by an index ray of light. Taking the action on the alum at 100, that on the rock-salt in five successive experiments was 81, 77·3, 71, 62·5, 60·4. This increasing action on the alum was found to be caused by efflorescence, which took place rapidly in the vacuum, and rendered the crystal partially opaque. A fresh alum plate being taken, this and the rock salt were coated with lampblack and replaced in the apparatus, the black side away from the source of radiation, so that the radiation would pass through the crystal before reaching the lampblack. The action of radiation was in the proportion of blacked alum 100 to blacked rock-salt 73.

Rock-salt and glass were next tested against each other *in vacuo* in a torsion-balance. Professors Dewar and Tait say that rock-salt is inactive when the beam from a candle is thrown on it, while a glass disc is active. The author has failed to corroborate these results; he found the mean of several concordant observations to be—rock-salt 39, glass 40.

The Measurement of the Force.—The author describes a torsion-balance in which he is enabled to weigh the force of radiation from a candle, and give it in decimals of a grain. The principle of the instrument is that of W. Ritchie's torsion-balance, described in the Philosophical Transactions for 1830. The construction is somewhat complicated, and cannot be well described without reference to the diagrams which accompany the original paper. A light beam, having two square inches of pith at one end, is balanced on a very fine fibre of glass stretched horizontally in a tube, one end of the fibre being connected with a torsion-handle passing through the tube, and indicating angular movements on a graduated circle. The beam is cemented to the torsion-fibre, and the whole is enclosed in glass and connected with the mercury-pump and exhausted as perfectly as possible. A weight of 0·01 grain is so arranged that it can be placed on the pith or removed from it at pleasure. A ray of light from a lamp reflected from a mirror in the centre of the beam to a millimetre-scale 4 feet off shows the slightest movement. When the reflected ray points to zero, a turn of the torsion-handle in one or the other direction will raise or depress the pith end of the beam, and thus cause the index ray to travel along the scale to the right or to the left. If a small weight is placed on one end so as to depress it, and the torsion-handle is then turned, the tendency of the glass fibre to untwist itself will ultimately balance the downward pressure of the weight, and will again bring the index ray to zero. It was found that when the weight of the $\frac{1}{100}$ of a grain was placed on the pith surface, the torsion-handle had to be turned twenty-seven revolutions and 353°, or 10073° before the beam became horizontal. The downward pressure of the $\frac{1}{100}$ of a grain was therefore equivalent to the force of torsion of the glass thread when twisted through 10073°.

The author next ascertained what was the smallest amount of weight which the balance would indicate. He found that 1° of torsion gave a very decided movement of the index ray of light, a torsion of 10073° balancing the $\frac{1}{100}$ of a grain, while 10074° overbalanced it. The balance will therefore turn to the $\frac{99}{100000000}$ of a grain.

Divide a grain weight into a million parts, place one of them on the pan of the balance, and the beam will be instantly depressed.

Weighed in this balance the mechanical force of a candle 12 inches off was found to be 0·000444 grain; of a candle 6 inches off 0·001772 grain. At half the distance the weight of radiation should be four times, or 0·001776 grain; the difference between theory and experiment being only four millionths of a grain is a sufficient proof that the indications of this instrument, like those of the apparatus previously described by the author, follow rigidly the law of inverse squares. An examination of the differences between the separate observations and the mean shows that the author's estimate of the sensitiveness

of his balance is not excessive, and that in practice it will safely indicate the millionth of a grain.

One observation of the weight of sunlight is given; it was taken on December 13; but the sun was so obscured by thin clouds and haze that it was only equal to 10·2 candles 6 inches off. Calculating from this datum, it is seen that the pressure of sunshine is 2·3 tons per square mile.

The author promises further observations with this instrument, not only in photometry and in the repulsion caused by radiation, but in other branches of science in which the possession of a balance of such incredible delicacy is likely to furnish valuable results.

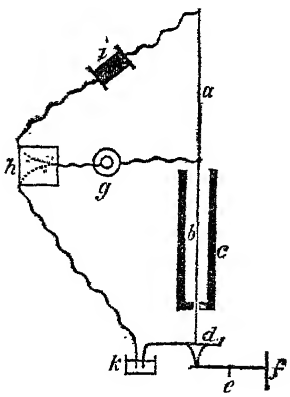
SCIENCE IN GERMANY

(*From a German Correspondent.*)

A FEW years ago Edlund attempted to decide the question whether the galvanic current is capable of directly altering the volume of a conductor through which it flows, or not, *i.e.*, whether changes of volume were demonstrable that were independent of the heat produced in the conducting wire? The results of his experiments appeared to furnish an affirmative answer to this question. More recently, Streintz published an investigation, the result of which was a confirmation of Edlund's view on the expanding power of the galvanic current. The expanding action found by Edlund was from 2·8 to 6·5 per cent. of the action of the heat simultaneously produced; that found by Streintz was considerably greater. In soft iron it amounted to 27 per cent. of the action of the heat.

From the fundamental importance which attaches to this question, in relation to the theory of galvanism, and from the difficulty of demonstrating the volume-changes referred to, apart from the actions of the heat simultaneously produced, it was desirable that the subject should be investigated by a method as free from error as possible. Such an investigation has lately been carried out by Herr Exner, in Vienna. The essential points of his method are as follows:—

Two pieces, *a* and *b*, of the same wire, about equally long, were suspended vertically one over the other, as indicated schematically in the figure. The lower piece, *b*, passed centrally through a glass tube, *c*, which was quite open above, but closed below with a cork, which merely gave passage to the wire *b* by a short glass tube



(2mm. wide) inserted in it. From the lower end of the wire *b* hung the plate *d* for holding weights. This was furnished at its base with a sharp iron point, meant to act on one arm of a lever which could be turned about *e*, while the other arm bore the mirror *f* at right-angles to its axis, and so in a vertical plane. If the image of a vertical scale were observed in this mirror with a telescope, the least change in length of the wires *a* and *b* could thereby be perceived. From the point of connection between *a* and *b* a wire was connected with the battery *g*. The other pole of the battery was connected with the commutator *h*, and thus the current could be sent either through the rheostat *i* to the suspending point of the wire *a* and through the latter back to the battery, or on the other side to the mercury cup *k*, in which is dipped the bent end of a short copper wire soldered to the plate, *d*, establishing thus a conductive connection between the commutator *h* and the wire *b*. Through the latter the current then went back to the battery. One could thus easily send the current successively through each of the two wire-pieces, *a* and *b*, separately, and so observe the elongation experienced by each. Since, as has been said, the two pieces *a* and *b* were not exactly equal in length, their elongations were also not exactly equal; to make them equal, the rheostat *i* was inserted, by which the resistance in the circuit *g h i a g* was so regulated, that with unchanged battery the successively observed elongations of *a* and *b* were the same. Water was now allowed to pass through the glass tube *c*, in order to take away as much as possible of the heat produced in the wire *b* by the galvanic current. If, now, the current passed through *b*, only the elongation which might occur independently of the heat action of the current would be observed, the heat produced being removed by the flowing water.[1] If, however, the current passed through *a*, both an elongation produced in *a* through direct action of the current, and the elongation through action of heat would be observed at the same time. [These experiments might of course also be made with only one piece of wire, *e.g.* *b*. The second piece *a*, serves only for making the obvervations more quickly in succession.]

It was found that the galvanic expansion expressed in percentage of the heat-expansion was only about 1·2 to 2·2 per cent.; and no connection was recognisable with the nature of the metal employed. If it be considered that these values, of course, can only be an upper limit, it will follow from the smallness of the effect obtained that there is no sufficient ground for the hypothesis of a special expansion-power of the galvanic current. There can hardly be any doubt that the slight expansion which the water-inclosed wire still shows is simply and alone due to the heat remaining in it. W.

THE INTERNATIONAL METRIC COMMISSION AT PARIS

IN previous numbers of NATURE[2] some information has been given of the proceedings of the International Metric Commission of Paris, and of the progress of their work in providing new international standards of the metric system. The construction of the new standard metres and kilogrammes of platinum-iridium, which was entrusted to the French section of the Commission, is now approaching completion, and their comparisons with the old standards of the Archives and with each other will probably be commenced early this spring.

It has been already explained that the definitive verification of the new standards was entrusted by the Commission to a permanent committee of twelve of their members, each representing one of the principal civilised countries interested. For the purposes of providing the committee with the necessary means of exercising their duties, and of giving an authoritative international character to the new standards, and to the regulations to be adopted for the custody and use of the new international metric prototypes, a diplomatic conference was held at Paris in March 1875, when a convention was entered into for effecting these objects.

Papers relating to the meeting and proceedings of this diplomatic conference, drawn up by Mr. Chisholm, the Warden of the Standards, who was the representative of

[1] It may happen that the heat of the wire is not entirely carried off by the flowing water.

[2] Vol. vii. pp. 197 and 237; vol. viii. p. 403; vol. x. p. 130.

Great Britain at the Conference, were laid before both Houses of Parliament last session by Her Majesty's command. Some further information upon the subject is contained in the Ninth Annual Report of the Warden of the Standards, recently published.

The following is a summary of the terms of the Convention, which bears date Paris, May 20, 1875.

By the two first Articles the high contracting parties agree to found and maintain at their common expense an International Bureau of Weights and Measures, scientific and permanent, its seat to be at Paris. The French Government will undertake to facilitate the acquisition, or if requisite, the construction of a building to be specially appropriated for this purpose.

Article 3 fixes the conditions under which the International Bureau will execute its functions. It is to be placed under the exclusive direction and superintendence of an International Committee of Weights and Measures, which itself is to be under the authority of a General Conference of Weights and Measures formed of delegates from all the contracting Governments.

The President for the time being of the Academy of Sciences at Paris is to be the President of the General Conference of Weights and Measures. But this body will not be called into existence until the verification of all the new standards shall have been completed, when it will be convoked for the purposes of sanctioning them and their distribution. All the Governments who send delegates to the International Metric Commission will be entitled to be represented at the General Conference.

Articles 5 and 6 relate to the organisation of the International Bureau, the International Committee, and the Conference General. The duties of the International Bureau are specified as follows:—The verification and conservation of the new metric prototypes of the metre and kilogramme, the construction of which has been entrusted to the French Section of the International Metric Commission; the verification of all the copies of these prototypes and their periodical comparisons; the verification and comparison of geodesical measuring instruments; and the comparison and verification of standards and scales of precision.

Articles 7, 9, and 10 fix the establishment of the International Bureau and the mode of defraying the expenses by contributions from all the contracting governments, according to a scale based on the respective amounts of their actual population.

These expenses are limited by Articles 5 and 6 of the Regulations annexed to the Convention to the total amount of 400,000 francs (16,000*l.*) for establishing the Bureau and providing it with all the requisite instruments, together with an annual sum not exceeding 100,000 francs (4,000*l.*) for the current expenditure, reducible to 50,000 francs (2,000*l.*), after the completion and distribution of the new national metric standards.

Articles 11, 12, 13 of the Convention reserve the right to every other civilised state to take part in it, under specified conditions; and enable the contracting parties by common agreement to make all such modifications in the terms of the Convention as may be found by experience useful; they also allow any of the contracting parties to withdraw from the Convention at the expiration of a term of twelve years.

A series of Regulations are annexed to the Convention, which fix the details of the organisation of the International Bureau, and of the composition and functions of the International Metric Committee and of the General Conference. Some transitory provisions are also annexed, relating to the completion of the construction of the new standards by the French Section, and their verification and distribution; as well as the mode of constituting the new International Committee and the General Conference.

At the Conference, the sittings of which were continued during March and April 1875, twenty of the principal civilised countries were represented, viz.:—Germany, Argentine Republic, Austria and Hungary, Belgium, Brazil, Denmark, Spain, United States of America, France, Great Britain, Greece, Italy, Holland, Peru, Portugal, Russia, Sweden and Norway, Switzerland, Turkey, and Venezuela.

The Convention was signed by the plenipotentiaries of seventeen of these countries. The Governments of three countries—Great Britain, Holland, and Greece—declined to take part in the Convention. They were willing to take part in it, and to contribute towards the expenses of the International Bureau, if its objects were limited to the verification of the new metric standards and the custody and use of the new prototypes, but they refused to take part in a Convention which established a permanent international institution for other and larger scientific objects, and for promoting the progress of the Metric System.

Further grounds for the refusal of the British Government were that by the terms of the Convention the International Metric Commission, to which delegates from this country were appointed by the Government, was virtually suppressed, and its functions and duties transferred to the new Committee; that the *propagation* of the metric system was declared to be one of the primary duties of the new General Conference, thus sanctioning the objectionable precedent of directly authorising a scientific body to interfere with national usages in countries where the metric system has not been adopted.

The result of their Governments declining to take part in the Convention has been that the representatives of Great Britain and of Holland have been compelled to decline to act upon the new International Committee, which was fixed by the Convention to be formed of the twelve members of the Permanent Committee, with the addition of the representatives of Italy and Switzerland. The Committee now consists of the following twelve members, who are to have the direction of the International Bureau:—

General Ibañez,	representing	Spain, President.
Dr. Förster,	„	Germany.
Dr. J. Herr,	„	Austria.
M. Stas,	„	Belgium.
General Morin,	„	France.
Prof. Hilgard,	„	United States of America.
Dr. Wild,	„	Russia.
General Baron Wrede,	„	Sweden.
Prof. Broch,	„	Norway.
Husny Bey,	„	Turkey.
Prof. Govi,	„	Italy.
Dr. Hirsch,	„	Switzerland, Secretary.

Under the terms of the Convention, the ratifications were to be exchanged on Dec. 20, 1875, and the committee to enter on their full functions on Jan. 1, 1876. Meanwhile, as soon as the provisional instrument of the Convention was signed by the plenipotentiaries on April 15 last, the Committee were authorised at once to constitute themselves and to make their preliminary arrangements. They accordingly held five meetings and elected their president and secretary, as already stated, and they provisionally appointed Prof. Govi director of the International Bureau. By Article 6 of the Regulations annexed to the Convention, the yearly salary of the secretary to the Committee is fixed at 6,000 francs (240*l.*), and that of the director of the Bureau, who is to reside there, is fixed at 15,000 francs (600*l.*). The Committee at the same time selected the Pavillon Breteuil in the park of St. Cloud as the site of the Bureau.

On Dec. 20, 1875, the representatives of eleven out of the seventeen contracting Governments met at Versailles, and exchanged ratifications of the Convention. It was announced that the Governments of Austria and Hungary, the United States of America, and Portugal, had

not yet been able to obtain the sanction of their Legislatures for the ratification of the Convention, and they requested further time for this purpose. The Argentine Republic and Venezuela also requested further time, and the requests were granted. Brazil alone declined to ratify the Convention and take part in its objects.

Before the adjournment of the late French National Assembly, they passed a law which was introduced by the French Government to grant the Pavillon Breteuil at St. Cloud, with some adjoining land, to the directors of the International Bureau for the purposes of this scientific institution, so long as it shall continue in existence.

The following appear to be the approximate proportions which the several contracting States will have to contribute towards the expenses of the new International Metric Bureau, based on Article 20 of the Regulations, by which the unit of contribution is to be determined from the population of each State, expressed in millions, and multiplied by the coefficient 3 for those countries where the metric system is adopted compulsorily; by 2 where it is adopted permissively; and by 1 for other countries.

States.	Population in Millions.	Coefficient.	Product of Units.	Approximate Contributions.		
				Establishment.	Annual, First Period.	Annual, Second Period.
1. Germany	41	3	123	£2,353	£587	£294
2. Argentine Republic	2	1	2	38	10	5
3. { Austria	20	3	60 }	2,066	516	258
Hungary	16	3	48 }			
4. Belgium	5	3	15	287	72	36
5. Denmark	2	1	2	38	10	5
6. Spain	25	3	75	1,434	358	179
7. United States of America	42	2	84	1,607	402	201
8. France	38	3	114	2,181	545	272
9. Italy	27	3	81	1,550	387	194

If Great Britain had taken part in the Convention, the contribution from this country towards the expenses of establishing the International Bureau would have been about 600*l.*, and towards the annual expenditure for the first period about 150*l.* a year.

The International Committee are now therefore in a position at once to commence operations. They are to meet at least once a year, and between their session can deliberate and pass resolutions by correspondence. They considered that at least a year must elapse from Jan. 1, 1876, before their new building and instruments will be ready for use. They therefore passed a resolution charging their executive to notify to the French Section that the Committee would not be prepared to commence their comparisons and verifications of the new Metric Standards before the spring of 1877. This will give plenty of time to the French Section to complete the construction of these new Standards and to make all such comparisons with the Standards of the Archives and with each other as may be necessary to ascertain their values with the requisite precision, before delivering the Standards to the International Committee for definitive verification.

H. W. CHISHOLM

PHYSICAL SCIENCE IN SCHOOLS

IT may contribute profitably to the discussion of the subject of Physical Science in Schools, if I state briefly the experience of an effort, extending over twenty-eight years, to give this subject a prominent, if not its merited place in our work. I may say that my boys rarely go to a university, and are almost wholly absorbed in professions, manufactures, and commerce.

Mr. Tuckwell's propositions (NATURE, vol. xiii., p. 412) are good, but perhaps the following modifications are better:—

1. The business of a school is general education; the business of a university is special education.

2. The branches of study for the general education of a school should be Language, Mathematics, Natural Science, and Art.

3. Some knowledge of each of these should be imposed on every pupil; but each pupil should be allowed to apply himself chiefly to that branch of study for which he shows the most natural aptitude, and which therefore will *to him* be the best *means* of education.

4. The matriculation examinations for entrance to the universities should require a fixed standard of knowledge of all these branches of education; and give equal honours for excellence in either.

I think this would place science on an equal footing with language and mathematics, in both school and university, and would in due time relieve us of the conventional pedantry which regards language as the only sufficient standard of an educated man, and ignorance of the simplest elements of science as no disgrace.

Now for our own practice and experience. At nine or ten years of age our boys get simple lessons on wild flowers, which they collect, are taught to examine and describe, and write a simple account of; necessary help of course being given.

On graduating to the upper school, which they do from ten to twelve years of age, they get three hours a week for descriptive lessons on botanical and zoological subjects, with reproductions and as much of classification as is practicable; and on meteorological phenomena and heat, illustrated by the daily and seasonal variations that affect themselves. The object here is to cultivate the observing powers, to induce discrimination of distinctive features, and to promote a thoughtful apprehension of the most easily discerned natural phenomena.

In the next grade four hours are given to science, and the study becomes more special. Mechanics is the subject taken, and if this subject be treated simply, and care be taken not to overrun the mathematical knowledge, it may be made sufficiently attractive, and a valuable means of thoughtful training in science.

In the next grade two hours a week are taken from mechanics, and chemistry is begun.

In the next grade the other two hours are taken from mechanics, and given to physiology—1. Vegetable; 2. Animal; so that the subjects here are physiology and chemistry with manipulation. In this grade, also, one hour a week is taken from the two commonly given to geography, and given to political economy. The boys in this grade will also often give special time to chemical manipulation, and to practical work in physiology. We have also workshops where a considerable amount of very good work in both wood and metal is regularly turned out, play time only being used.

It may be that I am rather exacting on my own efforts, but I have never been satisfied with our science teaching, and the current discussion of the subject in NATURE has added very materially to my dissatisfaction. To be dis-

satisfied with one's work, however, is one thing; how to make it better is quite another. In chemistry we have perhaps all the means commonly employed. In physiology we can get objective illustrations brought into the class-room, and can use the microscope and diagrams. In mechanics our workshops supply practical work, but for the class-room we have only the most homely practical examples, and I know of no apparatus that is not cumbrous, needlessly costly, or ineffectual. Johnstone's admirable illustrations and the black-board are our chief agents. I would travel far to get a practical knowledge of means and methods by which we could improve our own, in teaching this subject.

I believe that such knowledge as I have indicated may be profitably given even to very young boys. They learn thereby to distinguish the precise features and qualities of natural objects, and the conditions of ordinary phenomena; and such teaching undoubtedly exercises in the best way the observing powers which develop much earlier than the reflective faculty. I am inclined to say that teaching elementary science to boys from ten to thirteen is a greater success than teaching grammar, *i.e.*, that the principles involved are more easily seen, excite more interest, and become therefore a better mental discipline. We rarely have boys come to us with any knowledge of science, and when they have, it has generally been acquired from lectures, and is worthless as a means of education. We do not lecture, but do real hard class-work, and take periodical examinations on this work, giving it equal value in these and our grade examinations with language and mathematics. We have no reason to believe that this work interferes with or deteriorates the work in language and mathematics, in which subjects we find our boys quite equal, and, except in very rare cases, I may say, superior to incomers of like power, and who have had no science teaching.

The great number of men eminent for their vast scientific attainments, who have achieved this eminence in spite of our non-scientific, I may almost say anti-scientific system of education, clearly indicates that many of us have an inherent scientific power or genius surpassing our power in any other direction. I plead for such that they have the same chance of being floated on their scientific voyage as the linguist and the mathematician have on theirs: and I have seen no satisfactory plea why they should not. Value for value I claim for the science man a higher status in our present social life than is due to either linguist or mathematician.

My experience as a schoolmaster has revealed to me many cases where the talent for language or mathematics has been so low that the education effected by these has been of the meanest kind; or where the incessant failure has produced a stolid ignorance, a kind of mental paralysis, most disheartening to all concerned. Such cases have come into my hands, and I have seen intelligence rekindled, and mental power aroused by simple science teaching, and the power even for other subjects enhanced thereby. I plead for these feeble ones. Is it not a crime to them to keep the mind fixed on what to them is abstruse and unintelligible, and to shut against them the inspiring book of nature, which may contain the only intellectual sunshine of which their being is susceptible?

Allesley Park College, Coventry T. WYLES

I shall be obliged if you will permit me to remind Mr. Wilson of certain passages in his article contained in "Essays on a Liberal Education."

In his letter (NATURE, vol. xiii. p. 373) Mr. Wilson writes:—

"I maintain, after trial, that it is unwise, and unscientific from an educational point of view, to attempt to teach science at schools to boys till they have attained a certain standard of knowledge in arithmetic, and a certain power of reasoning and language as shown by their attainments in geometry and Latin. Let science be held before them as a thing to be enjoyed when they are older and more advanced. It is spoiled for them, and they are spoiled for it by its being taught them too soon. The dicta of men like Faraday and Sir John Lubbock and Roscoe are misleading opinion on this point, and I wish to record my protest against them."

But in "Essays," &c., Mr. Wilson wrote:—"Moreover, the kind of knowledge that science offers is not only wide and interesting and elevating, but it is also exact; and this exactness is a very great merit. It is a knowledge of things and not of words. In the education of the upper classes there is too little of positive and exact knowledge. . . . And natural science supplies this want of clearness and certitude better than arithmetic or geometry." And again:—

"But here is even a stronger ground for advocating the introduction of science as an element in all liberal education, and that is its peculiar merit as a means of educating the mind. . . . All that can be said on this point has been said over and over again, and I can contribute nothing except my daily experience that what is said is true. . . . Science is the best teacher of accurate, acute, and exhaustive observation of what is. . . . And of all processes of reasoning it stands alone as the exhaustive illustration."

Giggleswick, April 4 W. MARSHALL WATTS

NOTES

THE date now finally fixed for the opening of the Scientific Loan Exhibition is the 1st of May. This delay is entirely owing to the unexpected richness and variety of the collection. Germany alone sends upwards of 2,500 objects, many of them of the greatest value. Although France has sent some very fine objects for exhibition, she will, on the whole, be rather poorly represented. The Italians are sending all the riches of their storehouse at Florence, including Galileo's telescopes.

ON the 31st ult. a meeting, at which several well-known English biologists were present, took place at the house of Dr. Burdon-Sanderson, at which the advisability of establishing a society or association for the purpose of promoting the progress of physiological research in England, was considered and discussed. Eventually the matter was referred to a committee, who will report to a future meeting; after which some conversation followed as to the question of legislation, the general feeling of those present being that no opposition ought to be made on the part of scientific men to any measure framed in accordance with the recommendations of the Royal Commission.

A MOVEMENT has been organised for erecting a monument to the late Jean Baptiste Donati. The idea originated with the professors of the Physical and Natural History Museum of Florence, and it is proposed to erect the monument in the new observatory of Arcetri, which was in a manner Donati's work. We are sure there are many admirers of Donati in this country who will gladly subscribe to such a monument. The foreign Legations and Consuls of Italy are authorised to receive and transmit subscriptions to the Committee for Donati's monument, to whom they may be sent direct, at the Natural History Museum, Florence.

IT is proposed to raise by subscription a fund for the purpose of establishing a Memorial in honour of the late Daniel Hanbury; the amount of each contribution not to exceed one guinea. The form suggested for the memorial is that of a medal to be called the "Hanbury" medal, to be awarded for original research in the Chemistry and Natural History of Drugs by investigators in any part of the world. Dr. Hooker, Sir George Burrows, Sir James Paget, Sir Robert Christison, Dr. Allman, Dr. Warren de la Rue, Prof. Abel, and Mr. T. Hyde

Hills, have already expressed their cordial approval of the movement, and consented to be placed on the Committee now in course of formation; Prof. Attfield and Messrs. Carteighe and Bremridge are acting provisionally as secretaries.

LIEUT. CAMERON arrived at Liverpool in the *Congo* on Sunday, and as might be expected, was received with the greatest enthusiasm. Besides his relatives there were present the Liverpool municipal authorities, and Mr. Tinne, as representative of the Royal Geographical Society. Lieut. Cameron was attacked by scurvy on reaching the west coast of Africa, but is now to all appearance quite recovered, and looks strong and well. On Monday he was quite the lion of Liverpool, where he was fêted and toasted and justly treated as a hero who has accomplished a great and useful work. He gives a glowing account of the interior of Africa, and hopes that his journeyings will lead to its commercial development. There is no doubt that at the meeting of the Geographical Society next Tuesday, in St. James's Hall, he will meet with a warm reception. On Tuesday he met with a hearty welcome on his return to Shoreham, near Sevenoaks, of which place his father is vicar.

A COMMISSION of the Geographical Society of Paris has awarded the Society's Great Medal to Dr. Nachtigal, the German North African explorer. It is stated that owing to the arrival of Lieut. Cameron, steps will be taken by the Society to award extraordinary honours to the British explorer who has done so much for African discovery. The anniversary meeting of the Geographical Society is to take place on the 9th of April.

A DISCOVERY of great importance to prehistoric archæology has just been made in France. On March 2, while some workmen were excavating in a quarry of Jurassic limestone, near the little commune of Cravanche, about three kilometres N.W. of Belfort, at the base of a hillock, they came upon a small opening which was found to lead into a cave of large dimensions. On entering the cavern its floor was found to be covered with human bones, so disposed as to lead to the belief that the cave formed a prehistoric place of sepulture. Magnificent stalagmitic columns rise from the floor, but without corresponding stalactites. It would seem as if these columns were partly natural and partly artificial, as they appear to be disposed in a sort of systematic method, after the form of dolmens. It is in these cavities that the multitude of bones have been found. The skulls are raised slightly above the level of the rest of the bodies, which appear to be in a somewhat bent position. Several polished flint weapons have also been found, three beautiful ornamented vases in the form of urns, polished stone bracelets, and a mat of plaited rushes. The cave itself is calculated to be about 36 metres long and about 12 in breadth and height; and numerous galleries, or side-caverns, run off the main one. Immediately on the discovery of the cavern, the authorities of Belfort took measures to guard it and the treasures it contains in the interests of science, and M. Félix Voulot, who has given great attention to the subject of prehistoric archæology, has been charged with carrying on the researches. M. Voulot hopes to be able to disengage from the stalagmitic covering at least one entire skeleton. There is no doubt that we have here important remains of the polished stone period, but it is confidently expected that further research will bring to light relics of a much older period; indeed the writer in the *Revue Scientifique*, of April 1, from which the above details are taken, hopes that remains will be found not only belonging to the Tertiary, but even to the Cretaceous period. The cavern is situated in a bed of one of the lower strata of the Jurassic period (lower oolite), "on the *exact limit* of the shore of the ancient Jurassic sea."

THE following arrangements of the Royal Institution lectures after Easter have been announced:—Prof. P. M. Duncan, F.R.S.: Four lectures on the Comparative Geology and former Physical Geographies of India, Australia, and South Africa; on Tuesdays, April 25 to May 16. Prof. Tyndall, D.C.L., LL.D., F.R.S.: Seven lectures on Voltaic Electricity; on Thursdays, April 27 to June 8. Prof. W. K. Clifford, F.R.S.: Two lectures on the Present Relations of Science and Philosophy; on Saturdays, April 29 and May 6. Prof. W. G. Adams, F.R.S.: Three lectures on some of Wheatstone's Discoveries and Inventions; on Tuesdays, May 23 to June 6. Frederick J. Furnivall: Two lectures on Chaucer; on Saturdays, May 13 and 20. J. A. Symonds: Three lectures on the Medici in relation to the Renaissance; on Saturdays, May 27 to June 10. The Friday evening meetings will be resumed on April 28, at 8 P.M., when Prof. Gladstone will give a discourse on Methods of Chemical Decomposition illustrated by Water. Discourses will probably be given by G. J. Romanes, W. Froude, C. T. Newton, J. F. Moulton, Sir John Lubbock, and Prof. Tyndall.

IN the Mauritius *Overland Commercial Gazette* of March 3, Mr. Meldrum refers to a small but violent cyclone which swept over the island on Feb. 19. Although its approach was announced by the Observatory on the previous day, it was only on the evening of the 18th that it was known with certainty that a gale was imminent. The wind was at its strongest between 2 and 7 A.M. on the 19th, and during that interval it had a velocity of 66·5 to 77·5 miles per hour. The lowest barometric pressure was 29·102 at 4 A.M. on the 19th, and during the night the mercury oscillated considerably. Between 3 and 4.30 A.M. several flashes of lightning were observed. The rainfall at the Observatory was only 2·94 inches. The chief interest of this cyclone is an unusual rate of progression, and the suddenness with which it came on. Its centre passed N. and N.W. of the island at a distance of forty to fifty miles. On the 23rd and 24th it was evident that another cyclone was approaching; fortunately, however, after approaching from the N.E. to about 160 miles of the colony, the storm recurved to the southward, otherwise the colony would have suffered severely. Mr. Meldrum mentions, as an interesting coincidence, that from the 10th to about the 22nd a large sun-spot was visible.

AT the concluding Gilchrist Lecture to the Students of the St. Thomas Charterhouse School of Science, Mr. W. E. Forster, M.P., occupied the chair, and spoke of the importance of teaching science in elementary schools, and of the ungrounded apprehension that thereby rudimentary education would be neglected. He believed it was the duty of the country to give children in elementary schools as much learning in science as they could obtain while they remained there, and should not be afraid to teach them science because their station in life was humble. He believed that if science were substantially and practically taught it would do nothing but good. He was well aware that some of those who had taken part in the education movement thought that if science were taught in elementary schools there would be increased danger of the neglect of good elementary teaching; but he did not think there was any ground for such apprehensions; on the contrary, he thought it would be found that, generally speaking, where science was taught best there was the best teaching of such elements as reading, writing, and arithmetic.

WE regret to hear of the death, at the age of sixty years, of Dr. Letheby, the well-known analyst, for many years Medical Officer of Health for the City of London, and Lecturer on Chemistry at the London Hospital. Dr. Letheby was a Fellow of the Linnean and Chemical Societies.

THE death is announced of Signor Severino Grattoni, the Italian engineer, who, amid great obstacles, carried out the execution of the Mont Cenis Tunnel.

THE Iron and Steel Institute concluded its London Meeting last Friday; the papers read were all of a purely technical

nature. There are now about 900 members of the Institute, the next meeting of which will be held in Leeds in September.

THE Institution of Naval Architects commences this year's session to-day, and will continue its meeting to-morrow and Saturday in the hall of the Society of Arts. Lord Hampton, G.C.B., D.C.L., president, will occupy the chair. Among the many papers to be read are the following:—On the unequal onward motion in the upper and lower currents in the wake of a ship, and the effects of this unequal motion on the action of the screw propeller, by Prof. Osborne Reynolds.—On the theory of pitching, by W. Froude, F.R.S., Vice-president.—On the telegraph-ship *Faraday*, by C. W. Merrifield, F.R.S., Associate Member of Council.—On the propulsion of bodies, by R. Griffiths.—On a new form of hydraulic propeller, by M. E. François.

AT the conclusion of Prof. Huxley's Course of Lectures at Jermyn Street, which we are reporting, Mr. F. Wilson proposed a vote of thanks to the lecturer, and alluded to the state of Prof. Huxley's health. The vote was enthusiastically responded to, and Prof. Huxley, in reply, remarked that the gentleman who had kindly proposed the vote of thanks was under a mistake about his health, he was never better in his life; but, as it had been truly said, "If you had been ill it took at least four years to persuade your friends that you were well again."

THE *Pandora*, Capt. Allen Young's yacht, is now being prepared at Southampton for another voyage to the Arctic regions in search of despatches from the expedition under the command of Capt. Nares. The yacht will be ready for sea in the course of a few weeks.

WE are requested to state that Mr. E. B. Tylor gives his lecture on "Ordeals and Oaths" to morrow evening at the Royal Institution; there seems to have been some misunderstanding as to the date.

WE believe there are a good many people who would wish to visit the *Challenger* on her return to England, while all her equipments are *in situ*, before she is gutted. We are sure that if the authorities are made aware of the existence of such a desire on the part of the public, they will make arrangements to gratify it.

ON Easter Monday and following days the Geologists' Association will make an excursion to Nottingham and Belvoir Castle.

IT is stated as probable that the site of the proposed International Exhibition at Paris in 1878 will be the Bois de Boulogne and Passy.

M. BALARD, the well-known natural philosopher, who has taken part in most of the International Exhibitions that have been held, has died at Paris at the age of seventy-four. M. Balard was a member of the Academy of Sciences for more than thirty years. He was Professor of Chemistry at the Sorbonne. He leaves no written book, but his teaching was much admired.

ON March 25 an earthquake was felt at Algiers and vicinity at 6h. 34m. in the morning. The duration was three seconds. A second movement, less intense, was felt at 7h. 2m. in the afternoon. In the evening a strong storm set in from the S.W., and a deluge of water followed.

WE have received a copy of the rules recently adopted for the Cumberland Association for the Advancement of Literature and Science. The Association consists mainly of a number of local societies in Cumberland, and will hold an annual meeting, at which reports will be read from the affiliated societies, and the objects of the Association furthered by lectures, papers, addresses, discussions, &c. The association intends to publish at its own expense such portions of its own or of any of the associated societies' communications as may be deemed advisable. The objects of the association are laudable, and we wish it success. Its first annual meeting will be held at Whitehaven in May.

WE would recommend to the notice of teachers, the Rev. George Henslow's paper on "The Practical Teaching of Natural Science in Schools," which is published in *The Educational Times* of March 1, and a paper in the April number by the Rev. P. Magniss, on "The Teaching of Natural Philosophy in Schools."

AT the College examination at Downing College, Cambridge, in June, a Foundation Scholarship, of the value of 80*l*. per annum, will be awarded for proficiency in Natural Science. Particulars may be obtained from the tutors of the College.

SEVERAL important German publications have been forwarded to us; we regret that we are unable to do little more than give their titles. They may all be obtained through Messrs. Williams and Norgate, of London and Edinburgh. Dr. Hermann Hager has published a fifth edition of his useful little work, "Das Mikroskop und seine Anwendung" (Berlin: Sprengen). It is intended as a guide to medical men, pharmacists, students, &c., and is largely illustrated.—"Werden und Vergehen" (Berlin: Bornträger) is the title of a work by Carus Sterne, of Berlin, in which an attempt is made to trace the development of the universe from the nebulous "world-cloud" to man. Its tone may be inferred from the fact that it is admiringly dedicated to Prof. Haeckel.—Prof. J. C. G. Lucae has completed his work on the Anatomy of the Seal and Otter, "Die Robbe und die Otter" (Frankfort: Winter), *Phoca vitulina* and *Lutra vulgaris*, a monument of minute research. The first part of this work we noticed in vol. viii., p. 222; the complete work contains thirty-two fine plates.—Dr. M. J. Schleiden has published a curious work on Salt—"Das Salz" (Leipzig: Engelmann), its purpose being to trace the history, the symbolism, and describe the various uses of salt to man. Its main object is to show what an important effect salt has had on human culture.—"Grundriss der anorganischen Chemie" (Leipzig: Voss) is the title of a handbook by Dr. Rudolf Arendt, intended for use in German Middle, Higher, and Training Schools.—Under the title of "Physiologisches Methodik" (Braunschweig: Vieweg) Dr. Richard Gscheidlen, of Breslau University, has published what seems an admirable handbook of practical physiology. It is profusely illustrated with beautifully-executed woodcuts.—Under the title of "Theoretische Kinematik, Grundzüge einer Theorie des Maschinenwesens" (Braunschweig: Vieweg und Sohn), Prof. Reuleaux has published a work on Mechanics which will, no doubt, take a first place among treatises on this subject. Messrs. Macmillan and Co. will shortly publish a translation of Prof. Reuleaux's work.

MESSRS. Williams and Norgate have sent us "Nouveaux Éléments de Physiologie Humaine" (Paris: Baillière), by Prof. H. Beaunis, a work which, we believe, will take a high rank as a text-book.—A French translation of the Guide to Analysis of Water, by Dr. Reichardt, of Jena, has been made by Prof. G. E. Strohl, of Nancy; it is published by Reinwald, of Paris, and sold here by Williams and Norgate.

UNDER the editorship of Mr. R. Brough Smyth there has been published a Descriptive Catalogue of Rocks, Minerals, and Fossils, illustrative of the Geology, Mineralogy, and Mining Resources of Victoria, Australia, intended for exhibition at the Philadelphia International Exhibition. The list contains altogether 880 specimens.

MESSRS. PARKER and Co. have published Prof. Prestwich's lecture "On the Geological Conditions affecting Water Supply to houses and towns, with special reference to the modes of supplying Oxford."

THE Prince of Wales is bringing home with him a large collection of living animals, including, among the most important, two Musk Deer, three Thars, a Manis, three adult Ostriches, four Elephants, five Tigers, three Leopards, sixteen Impeyan Pheasants, more than twenty Tragopans and Cheer Pheasants, several other Deer and Antelopes, together with Fruit Pigeons, Peafowl, &c. These His Royal Highness intends to have exhibited as one collection, and as such they will be deposited in the Gardens of the Zoological Society, a suitable house being in course of erection, and now nearly completed, for their reception.

THE additions to the Zoological Society's Gardens during the past week include a Lesser White-nosed Monkey (*Cercopithecus petaurista*) from West Africa, presented by Mr. F. Ward; a Common Marmoset (*Hapale jacchus*) from South-east Brazil, presented by Mrs. Cleaver; a Wild Sheep (*Ovis burrhel*), an Impeyan Pheasant (*Lophophorus impeyanus*) from the Himalayas, deposited; two Wheatears (*Saxicola œnanthe*), European, purchased; two Cuming's Octodons (*Octodon cumingi*) born in the Gardens.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 23.—"Description of a Mammalian Ovum in an early condition of Development," by E. A. Schäfer, Assist. Prof. of Physiology in Univ. College.

The author describes the ovum of the cat from five, in the stage where they were rendered evident as scarcely perceptible swellings in the cornua uteri. In their long axes they were $\frac{1}{7}$ inch long; in their short, $\frac{1}{10}$ inch. No mesoblast was anywhere present between the hypo- and epiblastic layers, which latter were clearly separable from one another and nearly in contact only in a small part, where only the cells of each were in more than single layers. At this spot also, the cellular elements of each layer being perfectly recognisable, an exquisitely fine pellicle, which in section appears as a mere line, passes over and forms a definite boundary to the outer surface of the hypoblast at the thickened area. This is named the *membrana limitans hypoblastica*, and is found to be perfectly homogeneous and continuous, becoming stained slightly with carmine, and is probably a cuticular formation produced by the underlying cells. This structure seems to have been as yet unnoticed; the mesoblast cells without doubt first appear outside it, which is in favour of the epiblastic origin of that layer.

"On the nature of the force producing the motion of a body exposed to rays of heat and light," by Arthur Schuster, Ph.D., Demonstrator in the Physical Laboratory of Owens College. Communicated by B. Stewart, F.R.S., Professor of Natural Philosophy in Owens College, Manchester.

Mr. Crookes has lately drawn attention to the mechanical action of a source of light on delicately suspended bodies *in vacuo*; I have made a few experiments with the view of finding out the seat of the reaction which evidently must tend to move either the enclosure or the source of light. I have found that the action and reaction is entirely between the light bodies suspended *in vacuo* and the exhausted vessel.

Mr. Crookes' "Light-Mill" was suspended by means of two cocoon fibres, forming a bifilar suspension from the top of a vessel which could be exhausted. A slight movement of the enclosure could be easily detected by means of a concave mirror attached to it. A beam of the oxyhydrogen lamp was concentrated on the light-mill, which then revolved about 200 times a minute.

The light was cut off at the beginning of the experiment by means of a screen, and the position of rest of the glass vessel was read off by means of the dot of light on the scale. The screen was then suddenly removed, and in every case a large deflection of the glass vessel was observed. The vessel was deflected in the opposite direction to that in which the mill turned. When the velocity of the mill had become constant, the vessel returned to its original position of rest, but on suddenly cutting off the light the vessel was again deflected, but in the opposite direction as on starting the experiment. The vessel therefore now turned in the same direction in which the mill turned.

These experiments are easily explained on the assumption that the force acting on the vessel enclosing the light-mill is exactly equal and opposite to that acting on the mill itself. While the velocity of the mill in one direction is increasing, a force acts in the opposite direction on the vessel. When the velocity has become constant, the force which tends to drive the mill round is exactly counterbalanced by the resistance which opposes the motion of the mill. The two forces acting on the vessel will therefore counterbalance, and the vessel will return to its original position of rest. When the light is cut off, the resistance will stop the motion of the mill. The reaction of the resistance will act on the enclosure, and the enclosure will turn in the same direction as the mill.

By means of the reaction on the enclosure I have been able to calculate the strength of the force; and I have found that the pressure on a surface on which the light of equal intensity to that used in my experiments falls is equal to that produced by the weight of a film of water equal in thickness to the length of a wave of violet light.

March 30.—"On the Placentation of the Lemurs," by Wm. Turner, M.B. (Lond.), Professor of Anatomy, University of Edinburgh. Communicated by Prof. Huxley, Sec. R.S.

In the introduction to this memoir a description was given of the observations made by M. Alphonse Milne-Edwards on the gravid uteri of several genera of lemurs. The author then proceeded to describe the gravid uteri of six lemurs which he had received from Dr. Andrew Davidson, of Antananarivo, Madagascar, viz., *Propithecus diadema*, *Lemur rufipes*, and *Indris brevicaudatus*. He then summarised the conclusions he had arrived at in the course of his dissections, and showed that the placenta in these animals was diffused, and presumably therefore non-deciduate. The paper concluded with a discussion of the bearing of these observations on the classification of the lemurs, and on the theory of the descent of the deciduate mammals from a primæval root-form of Prosimiæ.

"The Residual Charge of the Leyden Jar," by J. Hopkinson, M.A., D.Sc. Communicated by Prof. Sir William Thomson, F.R.S.

Linnean Society, March 16.—Prof. Allman, president, in the chair.—Messrs. Edward R. Alston and David Blair were elected Fellows of the Society.—Dr. J. Anderson communicated a note "On the plastron of the Gangetic Mud-turtle, *Emyda dura*," detailing an instance where eleven instead of the usual nine bones were present. This occurred in an embryo from the egg, and it further appears that ossification and coalescence of the extra pair of bones is coincident with birth.—Mr. A. W. Bennett read a paper "On the rate of growth of the flower-stalk of the hyacinth," in which he showed that the greatest energy of growth is in the lowermost part of the stalk. This agrees with the recorded observations respecting the relative growth of different nodes of a stem, where the greatest energy is always at a considerable distance from the apex. But it offers a contrast to the phenomena exhibited in the submerged flower-stalk of *Vallisneria*, where the greatest energy of growth is in the terminal portion beneath the flower-bud.—Mr. Francis Darwin laid before the Society the results of his observations "On the hygroscopic mechanism by which certain seeds are enabled to bury themselves in the ground." These related chiefly to the Feather-grass, *Stipa pennata*, but similar phenomena obtain in other grasses, in *Anemone montana* and certain of the Geraniaceæ (as Hanstein has recorded, 1868). The essential structures are—a sharp point with reflexed hairs, and a strong woody awn, so bent as to possess a lower vertically helical and an upper horizontal part. With moisture the spiral portion of the awn untwists, causing the horizontal part to revolve, while the flexure between them disappears and thus straightens the awn. A reversal of this process succeeds on the awn becoming dry. In the case of *Stipa* the long, feathery, horizontal part of the awn is easily entangled in low vegetation, and the seed retained vertically, with point on the ground. With wetting the awn untwists, but the horizontal part prevented from revolving, the rotation is transferred to the seed, which latter has superadded pressure of its point, by a conversion of the awn to straighten itself. Again, as the awn dries the seed is not pulled out of the ground, but curiously enough is thrust deeper down; the reflexed hairs being subservient. By such combinations and alternate actions complete burial of the seed ensues. The special advantage of seeds being thus imbedded is obscure; in *Stipa* being unconnected with germination, though possibly a

protection from birds. The effects of changes of temperature Mr. Darwin points out. Hildebrand's and Hanstein's explanations of the torsion he thinks inadequate. Darwin's observations prove it resides in the individual awn-cells. When isolated and dried these latter twist on their own axis, similarly in direction, &c., to the awn and with moisture untwist. Finally, this remarkable power is shown to depend on the molecular structure of the twisting cell-walls. Nägeli and others' researches into twisting cells have not led hitherto to their importance in plant life.—The Secretary briefly referred to a technical paper by the Rev. J. M. Crombie, "On the Lichens of Antarctic America collected by Dr. R. O. Cunningham during the Voyage of H.M.S. *Nassau*, 1867–9." In this ninety-seven species and varieties are recorded: twenty-four of these and a genus, *Endocena*, are attributed to be new.—A discussion on the potato fungus followed. At the President's request Mr. Carruthers reiterated the salient features of Prof. de Bary's recent investigations. He called attention to the difference in thickness of the mycelial threads carrying oospores and antheridia, to the septate character of the threads, and to other points collectively adverse to Mr. W. Smith's views of the "resting spore" of *Peronospora;* De Bary believing two fungi have been confounded. The Rev. M. Berkeley defended Mr. Smith's conclusions as opposed to De Bary's, asserting that as the former, by photographs and drawings from nature, had shown the sexual congress of antheridium and oogonium derived from the unequal sized spawn-threads, no reasonable doubt of their connection existed. Admitting De Bary's extensive knowledge of fungi, Mr. Berkeley, nevertheless, objected to his style of criticism. Mr. Smith himself read a long written reply answering De Bary's objections in detail. He averred that Sadebeck's recent observations supported his own as to two sizes of mycelial threads, and the other objections raised with regard to the oogonia and antheridia. As to septal character of the threads, this belongs to *Peronospora*, those of *Pythium* being destitute in this respect. He further alluded to the warty bodies of Montagne's *Artotrogus*, showing De Bary had misconceived their nature. The Strasbourg professor's animadversion on the life-history of Smith's "resting-spore" being yet incomplete is weakened when the former admits it may take a year to resolve, and as yet only nine months have elapsed since the discovery of the bodies in question. Other remarks pertaining to the "resting-spores" being found in dry leaves, after decay in water, and on perennial mycelium were made, Mr. Smith concluding that De Bary had not entirely comprehended his publications on the subject. Mr. Renny expressed his opinion that the points were not absoutely settled on either side, discrepancies still appearing to him to exist. De Bary's objections were allowable on the ground of his extensive acquaintance with the subject, while possibly Smith may not have given the exact value to what he saw. Mr. T. Dyer suggested that the bodies of the so-called *Artotrogus* may be but mycelial dilatations, and not true oogonia; on this ground a fresh investigation might be necessary to ascertain its relations to the questions at issue. Mr. A. Murray, Mr. Cooke, and Dr. Masters each made a few remarks. Mr. Carruthers, in conclusion, thought Mr. Renny had put the case fairly. De Bary only meant to question Smith's knowledge of the conidia, not that he was ignorant of the potato fungus; he, De Bary, may have misunderstood Smith's drawings, but in the elucidation of facts and truths he certainly could not fairly be accused of hypercriticism, seeing that he himself had carefully watched and studied the development, mode of hosts, &c., since 1874.

Geologists' Association, March 3.—Mr. William Carruthers, F.R.S., president, in the chair.—On the Bagshot sands in the Isle of Sheppey, by Major F. Duncan, D.C.L., F.G.S. A recent section, made with the object of lowering a road, has exposed a considerable part of Bagshot sands, colour pale or light yellow, with clay lines, resting on the top of the dark London clay. The distinctive features are absence of greensands, presence of thin layers and nodules of iron-sandstone, absence of fossils. As there is no discoloration of the sands at the base of the section the author thought they might have been sub-aerial deposits—blown sand; otherwise he considered that there would have been a shading off between the clays and the sands. This theory, the author thought, might serve to explain the well-known variability of this series.—On some rock fragments in the above-described section, by Mr. W. H. Shrubsole. These had been found 6 to 18 inches from the surface and were all igneous, except some specimens of hard sparry limestones. After discussing the possibility of these fragments having been brought to Sheppey by human agency, the author contended that, although their position in the described section may have been due to such a cause, still that they must originally have been conveyed on ice, towards the close of the Glacial epoch, and been stranded whilst Sheppey was emerging from the sea.—Known facts and unknown problems in Arctic geology, by Charles E. De Rance, F.G.S., H.M. Geol. Survey. The existing glacial phenomena of the Arctic regions, Greenland, and Spitzbergen, were described, marine shells of existing species occurring at heights of more than 1,000 feet above the sea, and living marine Crustacea in fresh-water lakes elevated many feet above the sea-level in Polaris Bay. The observations on the discoloration of the waters of the Arctic Ocean were dwelt upon, and the bearing on the phenomena observable on the English Glacial deposits. The crystalline rocks of the north coast of America and the Greenland coasts were referred to the Laurentian system, and the whole of this area stated to have been land, during the Lower Silurian epoch. The Upper Silurian, however, was shown to be well represented in all the islands of the Arctic Archipelago, and the "Ursa Stage" of Prof. Heer, Devonian, or Lower Carboniferous, with coal-seams, to be present in synclinals in the latter, and also to exist in Spitzbergen and Bear Island, as do the overlying mountain limestones. The Lias and Oolitic rocks of the Arctic Islands, East Greenland, and Spitzbergen were described, and the Cretaceous plant-bearing beds of West Greenland, and their associated coal-seams. The Miocene basalts of Mid-Greenland, with their associated plants, were mentioned as probably connected with the basalts of East Greenland, and as ranging to Spitzbergen.

Physical Society, March 25.—Prof. G. C. Foster, F.R.S., president, in the chair.—The following candidates were elected members of the society:—The Marquis of Salisbury, Prof. Liversidge, W. Ackroyd, Tolver Preston, W. Merritt.—Mr. O. J. Lodge, B.Sc., made a communication on the flow of electricity in a plate, in continuation of a paper which he read before the society on Feb. 26. In order to apply the principle of images already described to the flow of electricity in plates bounded by straight lines, it is necessary that the angles of the plate should be aliquot parts of 180°; and, since this condition excludes obtuse angles, the number of rectilinear figures which can be treated is very limited. They are rectangles, equilateral triangles, two cases of right-angled triangles, the two limiting cases of the isosceles triangle for which the equal angles are 0° and 90° respectively, and many cases of the general two-sided polygon or "wedge," including the regular two-sided polygon or "strip." Since the images of a pole in a wedge lie on a circle as in a kaleidoscope, Cotes' property of the circle may be applied to obtain expressions for the potential of any point, and for the electrical resistance of the plate to the flow from any number of point poles situated anywhere in it. The expressions are rather long, but they become simpler in certain special cases which were pointed out. Making the angle of the wedge vanish the expressions modify into corresponding expressions for the strip, the resistance expressions of which always contain hyperbolic trigonometrical functions of the positions of the poles. The potential functions for a circular sector also follow from a general case of the wedge. The general resistance formula, applied to the case of the isosceles right-angled triangle leads to some continued products, all of which are generalisations of Wallis' expressions for $\frac{\pi}{2}$. The product of these products, which is itself of the same form, has been reduced by Mr. J. W. L. Glaisher to the complete elliptic integral usually denoted by K, its modulus being Sin 45°. This quantity appears in all the resistance expressions for right-angled triangles and squares which the author has yet examined. The case of an equilateral triangle leads to more complex and interesting products, which were reduced by Mr. Glaisher to the product of two theta-functions, with Sin 75° as a modulus. When the conditions of flow are known in one rectilinear figure they may be extended to a large number of others by alternate processes of reflecting the plate in one of its own boundaries, and of cutting it along one of its straight flow or equipotential lines. Diagrams of such transition figures were shown. In order to obtain the resistance of a compound conductor by means of the known resistance of its components, it is necessary that the flow conditions in each component shall remain entirely unaffected by their being connected together. Thus if the resistance of a circuit consisting of two wires side by side is to be deduced from the resistance of the wires separately, by the ordinary method of adding their conductivities, it is

necessary either that the wires shall not touch each other, or that if they do, no flow shall pass across the junction. This rule is often overlooked, and the oversight has given rise in certain cases to a notion of electrical "interference." The concluding part of the paper has to do with the flow conditions when fine poles are combined with point poles in a sheet, especially when point electrodes are introduced into a sheet when a uniform current or "river" is flowing across the sheet.—Dr. Guthrie then communicated a fourth paper on salt solutions and attached water. It consists mainly of an account of an examination of the behaviour of a salt solution, when cooled below the freezing point of water. Having shown in previous communications that every salt solution, when of a certain strength solidifies as a whole, at a certain temperature as a cryohydrate, the present research was directed to the determination of the temperatures at which, (1) ice separates from solutions of strengths weaker than the cryohydrate, and (2), the anhydrous salt or some hydrate richer than the cryohydrate, separates from solutions stronger than the cryohydrate. About twenty typical salts have been examined in this manner, and curves were exhibited in which the abscissæ represent strengths, and the ordinates solidification temperatures. All the curves have a similar character and exhibit a point of contrary flexure, between the origin representing pure water at 0° C. and the cryohydrate. Between the cryohydrate and the 0° C. degree of saturation, they are nearly straight lines, and are continuous with the curves of solubility above 0° C. The joint effect of two salts in depressing the temperature of ice-formation was also examined. From previous experiments the general law that the temperature of a freezing mixture is identical with that of the solidification of the cryohydrate of the corresponding salt, appeared not to be the case with iodide of sodium. It now appears that this salt offers no exception to the general law and that what was previously mistaken for the cryohydrate is really a sub-cryohydrate solidifying at a higher temperature. Certain remarkable cases of supersaturation were discussed which show that a solution may be supersaturated in a 3-fold manner, (1) with regard to ice (2) with regard to a salt, and (3) with regard to the cryohydrate of the salt. The parallelism between a boiling saturated salt solution and a glaciating one was pointed out.

PARIS

Academy of Sciences, March 27.—Vice-Admiral Paris in the chair.—The following papers were read:—Influence of variations of pressure on the working of chronometers, by M. Yvon Villarceau.—On the small movements of an incompressible fluid in an elastic tube, by M. Resal. The velocity of propagation of waves is equal to the square root of the product of the coefficient of elasticity and the thickness of the tube divided by that of the diameter of the tube and the density of the liquid.—Observations of temperature at the Museum of Natural History during 1875, with electric thermometers placed in the air and in turf-covered and bare ground, by M. Becquerel. The temperature was, on an average, somewhat higher in the turf-covered ground than in the bare ground, and in the former it never descended below zero.—On the comparative movements of the thermometer and barometer during the commotion of March, 1876, by M. Sainte-Claire-Deville. The periodic oscillation of the temperature from 9th to 13th March did not fail to be produced, and the law of non-synchronic parallelism of temperature and pressure is realised even in the most sudden variations of these two elements.—Remarks *apropos* of Mr. Lockyer's communication on new lines of calcium, by M. Sainte Claire-Deville. In two neighbouring groups of mineral substances, there are most frequently two minerals belonging respectively to each, and characterised by the same basic element. Now of all simple bodies it is calcium that most commonly plays this double *rôle*. Is this connected with its double behaviour under the influence of dissociants?—Experiments on the schistosity of rocks, and the deformations of fossils correlative to this phenomenon; geological consequences of these experiments, by M. Daubrée (first part). The press used in these instructive experiments could give a total pressure of 100,000 kilogrammes on the plates.—Reproduction of Amblystoma observed in the museum, by M. Blanchard. The Amblystoma of Mexico is the adult form of the Axolotl, and the fact observed is important as disproving the idea of the sterility of certain Batrachians in the adult state.—Continued observations of solar protuberances during the second semester of 1875, by P. Secchi. These comprise seven rotations. It is a period of prolonged minimum; the absolute minimum not yet reached (March). Protuberances varying from 2 or 3 one day to 10 or 12 the next. The hydrogenic flames were commonly *straight*, though 2 or even 3 minutes in height (say 60 terrestrial diameters); this indicates great tranquility. The chromosphere was very low at the equator, but often reached a great height at the poles (24 and 30 seconds). This is the effect of displacement of maxima towards the poles.—Mr. Spottiswoode was elected correspondent in the section of Geometry, in room of the late M. Le Besgue.—Report on a memoir of M. Bourgoin, entitled "Researches in the succinic series."—Employment of coal-tar and of sulpho-carbonates against Phylloxera, by M. de la Vergne.—Analytic theory of the movements of Jupiter's satellites, by M. Souillart.—Results of actinometric measurements on the summit of Mont Blanc, by M. Violle.—Velocity of thermal flow in a bar of iron, by M. Decharme. The times taken by the flow to reach different points in the bar are directly proportional to the squares of the distances of these points from the heated end; or, the velocities of thermal flow are inversely proportional to the squares of the distances. (The cooling is slower than the heating).—Study on stratified light; memoir by M. Neyreneuf.—The elephants of Mont Dol; organogeny of the system of molar teeth of the mammoth, by M. Sirodot.—Photomicrographic researches on the transformation of collodion in photographic operations, by M. Girard. Microscopic examination of collodion enables one to know the nature of the layer and to follow the reactions produced in photographic impression.—On communications at a distance by water-courses, by M. Bourbouze (sealed packet deposited in 1870). Lines are dispensed with, and earth currents utilised.—On the conditions of immediate integrability of an expression with ordinary differentials of any order, by M. Pujet.—Impossibility of the equation $x^7 + y^7 + z^7 = 0$, by M. Pepin.—On the exchange of ammonia between natural waters and the atmosphere, by M. Schlœsing. The ammonia condensed by a given quantity of water increases rapidly with diminution of temperature. It is a mistake to suppose the ammonia of a cloud is condensed almost entirely in rain.—Sources of carbonic oxide; new mode of preparation of very concentrated formic acid, by M. Lorin. In this method dehydrated oxalic acid is used in place of sulphuric acid, with a formiate.—On the constitution of the excretory canal of the hermaphrodite organ in *Leucochron candidissima*, Beck, and in *Bulimus decollatus*, Linn., by M. Dubrueil.—On the relations between number of molar teeth in the dog and dimensions of the bones of the face, by M. Toussaint. The normal formula for molar teeth of the dog is $\frac{6}{7}$, but in the extreme, dissimilar types of bulldog and greyhound the formulæ of $\frac{5}{7}$ or $\frac{5}{6}$ for the former, and $\frac{7}{9}$ for the latter, are met with. One may follow the transformation of the formulæ by examining intermediate types.—Researches on the convergence and divergence of formulæ of Fourier's representation, by M. Paul de Bois Reymond.

THURSDAY, APRIL 13, 1876

A RESEARCH FUND FOR THE CHEMICAL SOCIETY

AN offer has lately been made to the Chemical Society, which has for its object the establishing of a fund to be applied in aiding the development of scientific chemistry. The offer comes from Dr. Longstaff, who proposes giving the society the sum of 1,000*l.*, on condition that at least an equal amount be raised and invested together with his gift, in approved security. To make this offer known to the Fellows of the Chemical Society, the following circular has been sent to them, and already the major part of the required 1,000*l.* has, in donations varying from 1*l.* to 100*l.*, been raised.

Chemical Society,
Burlington House, Piccadilly, W., March, 1876

Dear Sir,

I am instructed by the President and Council of the Chemical Society, to request your consideration of a matter, which they hope will elicit your interest and active co-operation.

The advancement of Chemical Science, which constitutes the special object of the Chemical Society, may be promoted chiefly in two ways:—

1. By facilitating the early acquirement by students of Chemistry of a knowledge of the results of chemical research carried on in this and other countries.

2. By affording direct assistance to workers in chemical science, with a view to encourage and facilitate their labours in experimental research.

The Chemical Society has sought from the time of its foundation to aid in the first of these objects by the publication of original papers communicated to the Society; and, during the last five years, a special guarantee fund and liberal aid from the British Association for the Advancement of Science have enabled the Society to establish, on a firm footing, the publication of monthly abstracts of original papers published in this country and abroad, on chemistry and allied branches of science.

The Chemical Society has also recently endeavoured, as far as its funds would permit, to afford assistance to chemists undertaking original investigations, by the extension of its library, and occasionally by grants of small sums of money, when pecuniary aid was applied for. The limited resources of the society have, however, restricted the number and amount of these grants within very narrow limits. In 1872, Mr. T. Hyde Hills placed at the disposal of the Chemical Society the sum of 10*l.* as the nucleus of a fund for promoting original research; and offered under certain conditions, made with the object of securing the co-operation of others, to contribute a like sum annually. This attempt of Mr. Hills to form a research fund was not, at the time, seconded. The Council have, however, recently received from Dr. G. D. Longstaff, one of the original members, the generous offer to place at the disposal of the society, the sum of one thousand pounds (1,000*l.*) towards establishing a permanent fund for promoting the advancement of Chemical Science, on the condition that not less than an equal amount be subscribed for the same purpose.

As the President and Council feel that such a fund would add much to the usefulness of their Society, and enable them to encourage still further the prosecution of Chemical Science, they are most desirous to secure to the Society the benefit of this munificent offer of Dr. Longstaff; and have therefore instructed me to ask your co-operation towards the attainment of this object.

I remain, Yours obediently,
WILLIAM J. RUSSELL, *Treasurer.*

Considering the use to be made of this fund, and the very large number of persons interested either in the scientific development of chemistry, or else in its many lucrative applications, it is not unreasonable to expect that a sum far larger than this 2,000*l.* will be raised.

The feeling among those most interested and most active in raising this fund, is that there should be, in the first place, a permanent fund, the dispensers of which should have large discretionary power as to how the income is to be spent, so long as it be strictly used for the advancement of scientific chemistry, and secondly, that this fund should be aided by annual subscriptions. It is hoped that the invested capital may from time to time be largely increased by gifts; possibly as the real character and object of such a fund as this becomes better understood and more widely known, it may receive legacies and bequests such as now are devoted to charitable or religious purposes.

The direct income arising from the money which is to be invested in accordance with Dr. Longstaff's conditions cannot amount to any large sum; it is therefore hoped, and not without reason, that many will aid the fund by annual subscription, and while some may probably limit their subscriptions to a definite number of years, others may be willing to subscribe as long as they are assured that good and useful work is being done with the money thus raised.

A fund of this compound character has certain advantages; the invested capital gives permanency and keeps alive the interest in it, the subscriptions help most materially towards forming an income which will more nearly approach the requirements of the case, and there are many who would rather that what they give should be used for immediate requirements than that it should be funded for the benefit of unknown and possibly never-to-exist requirements in time to come.

One point has been urged against such a fund as this; it is that we should look rather to the State to aid research than to private generosity, and that every private fund of this kind tends to relieve the Government of some of its obligations, whereas all scientific bodies ought rather to increase such obligations, not lessen them. On the other hand the State aid, if it is to be really efficient, must be such that it will at least to some extent open out a career for those willing and able to devote themselves successfully to original investigations; while from this fund no more could be expected than that it should afford a means by which some of the best known chemists of the day, as represented by the governing body of the Chemical Society, should have within their power the means of aiding particular investigations, publishing possibly important scientific tables or other data, and making important acquisitions of books or even instruments if such be specially required by the fellows of their Society in the prosecution of scientific investigation. Undoubtedly it is beyond all question that the sphere of usefulness of the Chemical Society will be much extended by the establishment of this research fund.

W. J. RUSSELL

TAIT'S "RECENT ADVANCES IN PHYSICAL SCIENCE"

Recent Advances in Physical Science. By P. G. Tait, M.A., formerly Fellow of St. Peter's College, Cambridge, Professor of Natural Philosophy in the University of Edinburgh. (London: Macmillan and Co., 1876.)

THESE lectures, we are told in the Preface, were given in the Spring of 1874, at the desire of a number of the friends of the author—mainly professional

men—who wished to obtain in this way a notion of the chief advances made in Natural Philosophy since their student days. The demand, therefore, which these lectures are intended to meet, is that of men who, though they have received a liberal education, in which the element of science has not been neglected, are too deeply engaged in their professional work to keep themselves abreast of contemporary science by regular study, but who are yet able to avoid falling behind by occasionally availing themselves of an hour with a scientific friend.

In lectures of this kind, therefore, we are not to look for the elaborate exposition and reiterated inculcation by which the facts and methods of science are impressed upon the minds of beginners. Still less are we to expect the forcible language and striking illustrations by which those who are past hope of being even beginners may be prevented from becoming conscious of intellectual exhaustion before the hour has elapsed. We are rather to listen to one who has climbed high on the hard and slippery peaks of science as he points out the grand features of the prospect to those who stand on a lower level but yet on the same solid foundation with himself.

In his own words he has "to point out a few of the principal peaks which we have to ascend, and of the more formidable abysses which we have to avoid."

As safety must come before success, it may be well to observe that the most formidable of all these abysses is that of *à priori* physics. The study of this branch of science as it is to be found in the works of Hegel, Herbart, and others, seems to furnish an unfailing source of recreation to those who are engaged in the less amusing researches of experimental physics. In our modern examinations those candidates who try to conceal their ignorance by sending up what appears to them to be the most plausible answer to a question, often help to relieve by their felicitous absurdities the tedious labours of the examiner. We have only to imagine that instead of the weary examiner we have the vigorous man of science, and instead of the timorous candidate, some great philosopher before whose inner vision the whole world of being and not-being, in its apparent contradiction and fundamental indifference, lies open; and we shall then have some faint idea of the mode in which the writings of these philosophers may be destined to contribute to the merriment, if not to the happiness of the coming race.

We are glad to find, however, that in spite of the contempt which Prof. Tait pours upon the *à priori* physics of non-experimental philosophers, he admits that there is a true science of metaphysics which discusses the fundamental ideas of all science and knowledge, not by shutting out all the facts of experience, but by calling in all the evidence obtainable from the whole circle of the science.

In fact one of the greatest benefits which the advance of science has conferred on the world at large is that words and phrases have been gradually introduced into ordinary language which are consistent with true scientific ideas, and that these have displaced words and phrases which implied false ideas about nature, so that each generation, as it learns its mother tongue, finds it better adapted to express what really exists, and less suggestive of what is not.

We have only to read the expositions of science in the seventeenth century to see that they are addressed to students whose minds were imbued with prejudices and superstitions which are now known only to archæologists. Those who have the good fortune to be born in these latter times can hardly realise the reasons why certain natural phenomena rather than others were dignified or stigmatised with the name of paradoxes.

The man of science, if he confines himself to writing scientific books, can influence only the professed students of science, but if he can find an audience among men of business and men of action, who desire to keep up their scientific knowledge, he will at the same time help them to keep up a scientific habit of thought and expression. In this way a course of lectures like those of Prof. Tait may do something towards infusing a scientific spirit into the affairs and phraseology of business life, and since it is of the essence of science to speak of things as they are, the business phrases which satisfy this condition will gradually but surely displace those which describe things as they are not.

The subjects discussed in these lectures are the conservation, transformation, and dissipation of energy, spectrum analysis, the conduction of heat, and the structure of matter.

The experiments by which the lectures are illustrated are many of them new, and all of them well described. We may take the following as an example of Prof. Tait's method of illustrating the connexion of radiation with absorption:—

"I can show to a few at a time, but not in a marked way at a distance, the same phenomenon [as in Stewart's experiment with pottery], by taking a piece of platinum foil and writing letters upon it with ink. When it is once heated there is a deposit, on the surface of the otherwise polished platinum foil, of oxide of iron which tarnishes the surface and makes it absorb considerably more light than a polished reflecting surface will do. We should expect, then, when this is heated (as I now heat it in a powerful but very slightly luminous flame), and becomes in turn the source of light, to see bright letters on a dark ground. The difference of brightness is not so marked in this case as in the last, but still those who are nearest to me will see the phenomenon distinctly enough.

"But you will see another phenomenon still more startling on looking at the back of the heated foil instead of the front of it. You see faint traces of bright letters on the dark ground when I turn the inked side to you, but when I turn the other side you see dark letters on a bright ground. Now, the reason why on the one side we have bright letters on a dark ground, while the other side of the same piece of metal shows dark letters on a white ground, is still more confirmatory of the result of Balfour Stewart's experiment, which I have just stated, because these letters appear dark while at present cold, because they are absorbing more than the rest of the polished surface. They appear brighter than the polished surface when heated, because they radiate more; but just because they radiate more they must become colder—must be kept permanently colder than the rest of the foil, and therefore the parts at the back of the foil, behind those which are radiating most, remain permanently colder. This is made evident when we look at the side which is without any difference of surface, as we then see, by the relative amounts of brightness, a marked distinction between the parts which are hotter and those which are colder. This is a still more complete proof of Stewart's proposition."

We may also notice Prof. Tait's exposition of his views

with respect to the nature of comets and the origin of their light. He considers these bodies as consisting of swarms of distinct meteorites, which are illuminated partly by the light of the sun, but which also give out a light of their own arising from the numerous and violent collisions which are always taking place, especially near the nucleus where the swarm is densest. The most remarkable fact about this light is that discovered by Huggins, namely, that its spectrum is identical with that of a hydrocarbon.

We are sorry, however, not to find in this volume any exposition of that theory of Prof. Tait's concerning the development and manifestation of the tails of comets to which Sir W. Thomson referred in his presidential address to the British Association in 1871 as "Tait's beautiful sea-bird analogy." A "tactic arrangement" of brickbats extending over millions of miles would perhaps account for what at present appears from a dynamical point of view most paradoxical in the behaviour of comets' tails, but the dynamical explanation of this tactic arrangement itself seems still to remain as a desideratum of the theory.

J. CLERK MAXWELL

DR. BALL ON SCREWS

The Theory of Screws; a Study in the Dynamics of a Rigid Body. By R. S. Ball, LL.D., F.R.S., Andrews' Professor of Astronomy in the University of Dublin, and Royal Astronomer of Ireland. (Dublin: Hodges, Foster, and Co., 1876.)

DR. BALL has published several papers of late years on the subject here treated. The present volume contains the substance of these papers re-cast, with additional matter, and with a greatly improved terminology.

It has been shown by the combined labours of Poinsot, Chasles, and Möbius, that there is a perfect mathematical identity between the composition of forces and couples on the one hand, and of rotations and translations on the other. Every small movement of a rigid body consists of rotation round a definite line combined with sliding along it, in other words, consists of a *twist* on a definite screw, and every system of forces applied to a rigid body is reducible to a force along a definite line, together with a couple round it. The force is the analogue of the rotation, the couple is the analogue of the translation, and the combined action of the force and couple is called by Dr. Ball a *wrench* on a screw. In each case the screw consists of the definite line (fixed in position but unlimited in length), associated with a definite length, called the *pitch*, namely, the quotient of the translation by the rotation, or of the couple by the force. The *amplitude* of a twist is the magnitude of the rotation; the *intensity* of a wrench is the magnitude of the force. A twist, or its analogue a wrench, is defined by six numbers, one of which may be the amplitude or intensity, and the other five will then be common to all twists and wrenches on the same screw. A screw is therefore defined by five numbers.

When a body twists while acted on by a wrench, the work done by the latter is the continued product of the amplitude of the twist, the intensity of the wrench, and a third factor called the *virtual co-efficient* of the two screws. The virtual co-efficient is a symmetrical function of the two screws, and when it vanishes the two screws are called *reciprocal*. In other words two screws are said to be reciprocal if a wrench on one of them does no work in virtue of a twist on the other.

Taking six screws at random in space, we can express any twist as the resultant of six twists, one on each of these screws, and the amplitudes of the six components are called the *screw co-ordinates* of the resultant. Wrenches can be expressed in the same way, *intensity* being substituted for *amplitude*.

If we take five screws and combine arbitrary twists upon them, we obtain an infinite number of resultant twists on an infinite number of resultant screws. These resultant screws constitute a *screw-complex* of the 5th order; and in like manner we may have complexes of lower orders down to the 2nd.

Given a complex of the 5th order, one definite screw can be found which is reciprocal to it, that is to say, which is reciprocal to every screw contained in the complex. One practical application of this theorem is, that if a rigid body has freedom of the 5th order (or one degree of constraint), one definite screw can be found such that a wrench upon it can do no work on the body. Given any complex of the nth order, there is one definite complex of the $6 - n$th order that is reciprocal to it, in the sense that every screw of the one complex is reciprocal to every screw of the other.

In general problems on the dynamics of a rigid body, it is usually advantageous to select the six screws of reference, so that each of them shall be reciprocal to the other five. Such screws are called *co-reciprocals*.

For example, in discussing the action of wrenches on a body which has freedom of the 4th order (two degrees of constraint), four of the co-reciprocals should be selected from the complex which defines the freedom, and the other two will then of necessity define that other complex of the 2nd order which is reciprocal to it and includes every wrench that can be exerted by the constraints. When an applied wrench is resolved into its components on these six co-reciprocals, the first four components determine the movement of the body, the other two being completely destroyed by the reaction of the constraints.

It is not to be imagined that a wrench applied to a free body tends in general to make it twist on the same screw on which the wrench lies. If, however, we take six screws coinciding two and two with the principal axes at the centre of mass, and having pitches $\pm a$, $\pm b$, $\pm c$, where a, b, c denote the radii of gyration round these axes, these six screws will possess the property in question—an impulsive wrench on any one of them produces an instantaneous twist on the same. Dr. Ball calls these the six *principal screws of inertia* for a free body, and he further shows that a constrained body has a smaller number of such screws, the defect from six being equal to the number of degrees of constraint.

Again, he shows that if a body has freedom of the nth order, and has a position of stable equilibrium under the action of forces which have a potential, n screws (called *harmonic* screws) can be found possessing the following property, viz., that the body can execute small oscillations on any one of them, and will execute such oscillations if it receive an arbitrary displacement and initial twist-velocity upon it. Also that any possible small oscillations of the body can be resolved into n independent oscillations on the harmonic screws.

We have said enough to indicate the richness of the ground which Dr. Ball has broken, and we would commend his treatise to the careful attention of mathematicians.

We could wish that a sharper line had been drawn between real and imaginary solutions, and also between results that are only true for screws of finite pitch and those that are true without this restriction. We also think that the convention which Dr. Ball proposes (footnote, p. 11) for removing ambiguity from the expression for the virtual coefficient, is defective, partly because he has overlooked the fact that the virtual coefficient of two screws is essentially signless until positive as distinguished from negative directions have been arbitrarily selected along them. When this selection has been made, the virtual coefficient is the value of the quaternion expression $-pS\alpha\beta + S\alpha\beta\gamma$, where p denotes the algebraical sum of the pitches, α and β unit-vectors parallel to the two selected positive directions, and γ the vector perpendicular from the screw α to the screw β. To express the same thing unambiguously without quaternions would require such a long specification as would weary the patience of our readers.

The value of Dr. Ball's book is enhanced by an appendix containing a very clear and interesting *résumé* of the literature of the subject, from Poinsot downwards. We may supplement this list by a reference to §§ 200, 201 of Thomson and Tait's "Treatise on Natural Philosophy," where one degree of constraint is shown to be reducible to the condition that "every longitudinal motion of a certain axis must be accompanied by a definite proportion of rotation about it." This comes very near to the indication of the one reciprocal screw by which such constraint may be defined. J. D. E.

OUR BOOK SHELF

Mittheilungen aus dem k. Zoologischen Museum zu Dresden. Herausgegeben mit Unterstützung der Generaldirection der k. Sammlungen für Kunst und Wissenschaft. Von Dr. A. B. Meyer, Director des königl. zoologischen Museums. 1 Heft mit Tafel i.-iv. (Dresden: Verlag von R. v. Zahn, 1875.)

THERE can be no question that the establishment of a journal in connection with a scientific institution is one of the very best methods of promoting the interests of the latter and obtaining for it more extended support. While the institution remains in one place, its journal travels about the world, makes its most recent acquisitions known to its supporters and correspondents, and encourages them to promote its welfare by further donations. Such being the case, Dr. Meyer has acted most wisely in endeavouring to resuscitate the somewhat decayed zoological branch of the Royal Museum of Dresden, by starting the present periodical. Dr. Meyer's recent travels and discoveries in the Eastern Archipelago have brought him much and deserved credit, to which, no doubt, he partly owes his present appointment. They have likewise supplied him with abundant materials for contributing valuable memoirs to his journal. Not unnaturally, therefore, the first number of the new periodical commences with papers containing the results of some of his own researches in the Eastern Islands. The first of them contains an account of a new Bird of Paradise, not actually discovered by Dr. Meyer himself, but by one of his correspondents since his return to Europe. *Diphyllodes Gulielmi III.*, as this splendid bird is named, in honour of the King of Holland, is said to be from the little known Papuan island of Waygiou, and vies in brilliancy of plumage and elaborate excess of feathered ornaments with the finest species of this gorgeous family. Descriptions of other novelties in the class of birds discovered by Dr. Meyer himself, together with additional notes on little known species, complete this interesting memoir. Another paper by Herr Kirsch contains descriptions of new beetles from Malacca, from a large collection sent by Herr Eichhorn to the Royal Museum, and a third, which will be of special interest to our anthropological friends, is devoted to an account of 135 Papuan skulls obtained in New Guinea and Mysore by Dr. Meyer himself. We observe that a second part of the *Mittheilungen* is announced for publication early in the present year, so that we may expect shortly to have an opportunity of bringing further labours of Dr. Meyer and his assistants to the knowledge of our readers.

Table of British Sedimentary and Fossiliferous Strata. By Henry William Bristow, F.R.S., F.G.S., Director of the Geological Survey of England and Wales. The Description of Life Groups and Distribution by R. Etheridge, F.R.S. Second Edition, revised. (London: Edward Stanford.)

THIS is an admirable and evidently very carefully prepared table, which is well suited for the use of students, science classes, and schools. In it Mr. Bristow has managed to embody a vast amount of information, which could only be obtained and verified by the consultation and comparison of a great number of maps and documents; and for this service all engaged in teaching the science of geology are greatly indebted to him. The foreign equivalents of the British rocks are only given in such cases as that of the Trias, in which our own series is incomplete. Mr. Etheridge's contribution to the work consists in a very valuable palæontological digest, in which the order of succession of the different forms of plants and animals is clearly described. The only points which seem to call for critical remark in this excellent work is the use of the term *Laurentian* for the so-called "Fundamental Gneiss" of Scotland, and the manner in which the name of Cambrian is employed. There is absolutely no evidence whatever whereby the geologist is able to correlate the azoic rocks on the opposite sides of the Atlantic, and therefore the application of the term Laurentian to any British formation would scarcely appear to be justifiable. In the long-vexed question as to the boundary between the Silurian and Cambrian systems, we regret to find Mr. Bristow adopting the extreme views of the late Sir Roderick Murchison, and confining the name of Cambrian to a few almost unfossiliferous rocks quite at the base of the series. The line of division at the top of the Tremadoc slates, which was adopted both by Lyell and Phillips, has the advantage of making the British Cambrian system, as now defined by Hicks, very closely agree with the "Primordial" of Barrande; and we hope that in a future edition of this table, which we doubt not will soon be called for, the author may see his way to the adoption of it.

Catechism of Chemistry. New edition by Robert James Mann, M.D., &c. (London: Edward Stanford, 1876.)

PERHAPS no better illustration of the truth of Pope's line—

"For fools rush in where angels fear to tread"—

can be cited than the method employed in the manufacture of many of the so-called scientific elementary text-books, a series of which *must* be put forth by every publisher. The "Catechism" before us is a typical example of a book constructed on this most pernicious method. The author appears to have learned a little chemistry from works which were in vogue a quarter of a century ago, and to have tacked on to this knowledge a

smattering of the more recent development of the science. Being thus completely furnished, he has entered the arena. The result is altogether what might have been expected. Inaccuracy of statement, meaningless definitions, sins of omission and of commission, abound. If anyone wishes to learn the rudiments of chemistry, let him eschew this catechism as he would poison.

M. M. P. M.

Summer Holidays in Brittany. By Thomas J. Hutchinson. With Map and Illustrations. (London: Sampson Low and Co., 1876.)

MR. HUTCHINSON is well known, among other things, for his researches among Peruvian antiquities, and therefore, to his tour in Brittany he brought a trained observation. He has managed to write a very pleasant book on rather a worn subject, a book which is likely to give its readers a desire to follow the author's example. Indeed it might form a very useful guide-book for the district traversed by Mr. Hutchinson, and would have the advantage of being much more pleasant reading than guide-books generally are. Mr. Hutchinson evidently made good use of his time when in Brittany, and to those who have not read much on the subject the book will furnish a great deal of information on the nature of the country, the characteristics and manners and customs of the people, the antiquities, historic and prehistoric, the ecclesiastical and political history, and many other interesting points. A very good map and some fair illustrations add to the value of the book.

LETTERS TO THE EDITOR

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.*]

Colour of Flowers Grown in the Dark

IN NATURE, vol. xiii. p. 348, Mr. Thiselton Dyer gives an extract from Sachs's "Text-book of Botany" to the effect that no change is produced in the colour of flowers by growing them in the dark. This led to a letter from Mr. J. C. Costerus (vol. xiii. p. 427), calling attention to the results obtained by Askenasy, published in 1876, who found that some kinds were changed in colour, and some not changed. In the autumn of 1873 I made a number of experiments on this subject, and published a short account of them in the same year in the *Quarterly Journal of Science*, vol. iii. p. 474. I came to the same conclusion as Askenasy has come to, and was also able to establish some important generalisations. I will only mention a few special instances. I was unable to cause any change in the colour of the common Orange Lily (*Lilium aurantiacum*), whereas I found that a very considerable change was produced in the case of *Erysimum Peroffskianum* by only a moderate degree of darkness. This may perhaps be owing to the fact that the orange tint of these two kinds of flowers is due to entirely different substances. That of the lily is due to what I have called orange xanthophyll, whereas that of the other flower is due to a much less stable compound, giving an entirely different spectrum, met with also in the orange marigold, and therefore named by me *Calendula xanthine*. Comparing together the mixed colouring matters found in an equal weight of the petals, I found that the amount of the *Calendula xanthine* was only half as great in the petals grown in the dark, whereas the more yellow constituents were reduced only to three-quarters, so that the general colour was more yellow. I found that a similar change could be produced in the case of the marigold. If shaded when the flowers are somewhat grown, the total colour may be very considerably reduced without there being any material change in the ratios of the different colouring matters, whereas when grown in the dark from a very small bud, the ratios are changed, as in the case of *Erysimum*. Growing flowers in the dark seems to stop the normal development to a greater or less extent according to the nature of the colouring-matters, the effect being the greatest in the case of those substances which are the most easily decomposed. We thus find what appears at first sight to be a very unlikely result, viz., that those constituents which, when dissolved out from the petals, are the most easily discolorised by exposure to light, are formed in relatively greater amount when the flowers are grown in the light, which is easily explained if we assume that a higher vital power, depending on the presence of light, is necessary to overcome the more powerful chemical affinities of the less stable compounds.

H. C. SORBY

The Ash Seed Screw

MR. STEPHEN WILSON remarks, in his note on this subject (NATURE, vol. xiii., p. 428), "Why the seed generally becomes twisted as it dries is a very interesting question. But what seems to me the most remarkable fact about this phenomenon is, that in every case, and in all trees alike, the thread of the screw is in one direction." He also alludes to the uniformity in the direction of torsion in the awns of two species of oat. Torsion of all kinds occurring in plants is usually assumed to be due to unequal longitudinal tension (see Sach's "Handbook," p. 770). In a paper read before the Linnean Society, March 16, I pointed out that the uniformity in the *direction* of the torsion cannot be thus accounted for; and a totally different explanation was given of the twisting and untwisting of the awns of certain fruits (*Avena elatior* among the number) when they are dried and moistened. It was shown that the power of torsion resides in the individual cells of which the awn is constructed, and tha it is by their combined action that the awn, as a whole, becomes twisted in drying. It appeared to me extremely probable that the same explanation would hold good for the twisted wing of the ash fruit. I therefore boiled one in nitric acid and chlorate of potassium, by which means the woody tissue is separated into its constituent cells. These were then teazed out on a slip of glass and thoroughly dried over a lamp, and it was found that many of them had become twisted on their axes; and, which is important, that they were all *twisted in the same direction as the fruit itself.* This artificial drying represents the natural drying process which occurs during the ripening of the fruit. In both cases contraction and consequent torsion result from the loss of water, but in the natural process the cells not being free to twist independently, are compelled to combine in producing that torsion of the whole fruit which we are considering. It is interesting to find the same principle holding good in the case of the ash screw as in that of the awns of various Gramineæ and Geraniaceæ, and the twisted tails of the achenes in *Anemone montana*. Moreover, I strongly suspect that the principle of the torsion of an organ being dependent on the twisting of its constituent cells is capable of wider extension, so as to embrace the torsion of the stems of twining plants, &c. This subject I hope immediately to investigate.

FRANCIS DARWIN

P.S.—The samara of the sycamore is a more efficient parachute than that of the ash, but the wing has no appreciable twist, and there is no uniformity in the direction of rotation assumed as the fruits fall to the ground.

Down, Beckenham, April 4

The Animal of Millepora

IT is a remarkable fact that during all the discussions on the late L. Agassiz's statements regarding the animal of Millepora some very careful drawings of it have been in the possession of Major-General Nelson, R.E. They were done by himself during his residence at Bermuda at the time when he was writing that communication to the Geological Society on the reefs and general structure of the islands which has made *Lieut. Nelson, R.E.*, a name of mark.

In common with most naturalists, I had expected that soon after the *Challenger* reached Bermuda, we should have had a satisfactory description of this very interesting polyp, so that the truth, or the contrary, of Agassiz's description could be tested. But it was not until July in last year that any communication relating to the subject was sent off from the *Challenger*, the paper being read on Nov. 25, 1875, at the Royal Society. Mr. Moseley noticed therein that the examination of Millepora is beset with serious difficulties, he, however, states that there are large and small polyps, and that both kinds have tentacles, and "they appear to be four in number, and compound." He observes: "they are simply retracted by means of muscular fibres which are arranged round the base of the cylindrical stomach

radially, and that no mesenteries have been seen." Mr. Moseley was naturally dissatisfied with these poor results, and hoped to do better things at Hawaii. In the meantime I became aware of the value of the drawings I have already alluded to, and as I am at work on several subjects with Gen. Nelson, I sent a communication and the drawings to the "Annals and Magazine of Natural History" before the evening of April 6, when Mr. Moseley's paper on Millepora was heard by me at the Royal Society. It is a satisfaction for me to be able to state that Gen. Nelson's drawings prove that Agassiz saw a part of a polype, and that Mr. Moseley's beautiful delineations, far in advance of all, testify to the correctness of my fellow-worker. I do not credit the hydroid nature of the polyp now, any more than I did when writing the reports on the British fossil corals, and I believe Millepora to be an Actinozoan.

P. MARTIN DUNCAN

The Use of the Words "Weight" and "Mass"

THE relations between weight and mass, gravity and acceleration, are so well defined in all good treatises on dynamics, that it appears superfluous to dwell on these questions. But as it has been stated by Prof. Barrett, vol. xiii., p. 385, that the C. G. S. system of units has been introduced into the course of Mechanics in this College, I may be permitted to say that the system actually employed is not that referred to by your correspondent. I generally employ the kilogramme, metre, and second, and sometimes the foot, pound, and second, to measure a dynam or unit of force. The dynamometers alluded to as about to be exhibited at the Loan Exhibition of Scientific Instruments at South Kensington are suitable to the former system, and I use them for the measurement of dynams in kilogrammetres. One of these dynamometers is graduated for every 200 grammes up to 100 kilogrammes, the other for every 100 grammes up to 10 kilogrammes, and they cannot be depended on for results within the tenth of a kilogramme. Spring dynamometers, though suitable for the large units employed in mechanics, are totally unfit for measuring units on the C. G. S. system. I concur with Prof. Everett, in his book on this system, when he says:—"A spring balance, it is true, gives a direct measurement of force, but its indications are too rough for purposes of accuracy" (p. 8). Spring dynamometers are therefore unsuited to a system where the units are measured by $\frac{1}{981}$ of a gramme, or about $\frac{1}{65}$ of a grain, as in the C. G. S. system.

HENRY HENNESSY

Royal College of Science for Ireland, Dublin

The Physical Constitution of Steam

I BELIEVE the following remarks on the physical constitution of steam are in some degree original, in form at least, though perhaps not in substance.

Dr. Andrews has shown by his experimental researches on carbonic acid, that at a temperature above 31° C. or 88° F. the difference between the gaseous and the liquid states no longer exists. I quote the following brief statement from an admirable paper on the subject, by Prof. James Thomson, in the "Proceedings of the Belfast Natural History and Philosophical Society," 1872;—he is speaking of the case in which a given quantity of carbonic acid, of which part is in the gaseous and part in the liquid state, is kept at constant volume, while the temperature, and consequently the pressure, are gradually increased:—

"As the temperature and pressure are augmented, the gaseous part is always increasing in density, and the liquid part is diminishing in density, till at last the two come to have the same density with one another, and then they are perfectly alike in every respect, all distinction between them having vanished. At this stage the temperature is 31° C., and the pressure is about seventy-five atmospheres. Above this temperature of 31° no change of pressure can cause gasification or liquefaction; and above this pressure of about seventy-five atmospheres, no change of temperature can cause gasification or liquefaction."

This temperature of 31° C. is called by Dr. Andrews the critical temperature for carbonic acid. Above its critical temperature, although carbonic acid may have the density either of a gas or of a liquid, the two states are not sharply separated from each other as a liquid is from its vapour, but graduate into each other insensibly. It is believed that every gas and vapour has its own critical temperature. Those of the permanent gases are believed to be so low as to be unattainable by any known process. That of water or steam, on the contrary, is probably too high to be observed in a glass tube, and consequently too high to be directly observed at all: for the only known test of the critical temperature being attained, consists in the disappearance of the visible boundary surface between the liquid and the vapour or gas. My purpose is to show how the critical temperature for steam may be approximately estimated with a great degree of probability.

The fact that the latent heat of steam diminishes as the temperature increases, formerly seemed to me one of the strangest of all facts; but the above-mentioned properties of carbonic acid, and no doubt of all gases and vapours, make it quite intelligible.

The *latent heat* is defined as the heat given out when steam is condensed into water of its own temperature. The *total heat* is defined as the heat given out when steam is condensed into water at zero Centigrade, and is the sum of the latent heat and the temperature. According to Regnault, the relation between temperature and total heat is expressed by the formula—

$$\lambda = 606{\cdot}5 + {\cdot}305\,t.$$

λ being the total heat and t the temperature. This has been ascertained to be true from 0° to 230°, and if it is true for all temperatures, at a temperature of 872·7 the total heat and the temperature would be the same, and the latent heat would vanish: 872·7 is consequently the critical temperature which is deducible from the above formula for water.

JOSEPH JOHN MURPHY

Coloured Solar Halos

IN the interesting letters of Drs. Schuster and Frankland I note some remarks on the rarity of the apparition of complete halos about the sun in this country. Had I read these remarks some six years ago I should have passed them by without surprise. It so happened, however, that my attention was drawn to the subject of halos, coronas, &c., by Kämtz's "Lehrbuch der Meteorologie" about the year 1869, and I at once began to examine the sky near the sun every fine day, and note down any appearance of halos, fringes, &c. When I began, my impression was that I should rarely see the solar halo seeing that it had escaped me for several years. However, I soon found out my mistake, and the subjoined list, compiled from the observatory note-books, gives the number seen each month in 1874 and 1875. No doubt, several escaped my vigilance in some months and a few in others. The figures, at any rate, show that the phenomenon is by no means rare.

Solar Halos in 1874 *and* 1875.

	1874.	1875.		1874.	1875.
Jan.	0	2	July	3	4
Feb.	1	2	Aug.[1]	1	—
March	1	2	Sept.	2	4
April	11	4	Oct.	0	2
May	8	1	Nov.	3	0
June	11	2	Dec.	1	0

	Jan.	Feb.	March.
1876	1	0	8

Had I been quite sure that Dr. Schuster's remarks referred to the ordinary solar halo, this letter would have reached you a week ago or more. I will only add that the halos I have observed are nearly always complete (when the sun is high enough), that they are often very bright and most striking phenomena, and that the radius is usually about 22°.

Bermerside, Halifax, April 6

JOSEPH GLEDHILL

"The Effect of the Sun's Rotation and the Moon's Revolution on the Earth's Magnetism"

THE above was the title of an article by J. Allan Broun, published in NATURE, vol. xiii. p. 328.

The establishment of these facts, if they have not already been published, will aid amateur investigators very much in arriving at satisfactory conclusions in regard to the phenomenon above referred to.

First, from the revolutions of the sun, do the positively defined edges of sunspots always reappear at the same moment, and are their relative positions with regard to each other ever the same through a series of years, giving them a fixed and positive character, both as to position and time of revolution?

Second: At what times, with regard to the position and area of the largest and most numerous sunspots, and whether they are hidden by the revolution of the sun, or face the earth, is the

[1] I was from home most of this month in both years.

greatest effect observable in the differences of the earth's magnetism?

Third: Are the sun-spots caused by clouds or curtains outside, and hiding the apparent surface of the sun, or are they deep cavities through the same? STEPHEN W. ALLEN

Boston, U.S.A., March 27

Metachromism

I REFRAIN from replying to Mr. Petrie's second letter (p. 426) until after the appearance of the article to which Mr. Costerus refers (p. 427) on "Organic Colour Change."

In defence of Miller, however, I would just add that on p. 298, vol. ii. (fifth edition), occur the following words:—"The sodic dioxide, Na_2O_2, obtained by igniting sodium in oxygen is of a *pure white colour*." WM. ACKROYD

Royal Coll. of Chemistry, South Ken ington, April 3

Dr. Klein on the Small-pox of Sheep

I WRITE this note in order to inform you that, my attention having been directed to some alleged fallacies in some of my observations regarding the small-pox of sheep, I am at present engaged in reinvestigating the subject. E. KLEIN

The Brown Institution, April 11

OUR ASTRONOMICAL COLUMN

OLBERS' SUPPOSED VARIABLE STAR NEAR 53 VIRGINIS.—The only comet detected in the year 1796 was found by Olbers in Virgo on the night of March 31. On the following evening, at 8h. 55m., apparent time at Bremen, it was over a star of the seventh magnitude south—following 53 Virginis, and the light of the star was remarked to be little affected by the intervention of the comet. On March 1, 1797, desiring to fix more exactly the place of this star, Olbers found in its position one of only the tenth or eleventh magnitude, whereas in April previous, according to Schroeter, who appears to have compared the comet with it early on the morning of April 2, it was the brightest star in the immediate neighbourhood of 53 Virginis, and hence in Olbers' judgment "a seventh magnitude at least." Writing to Bode in March 1797 he directs attention to this star, as perhaps a more remarkable variable star than even χ Cygni. The circumstances preclude suspicion of a similar phenomenon to that described by Piazzi when the great comet of 1811 passed over his star XX. 197.

From the positions of the supposed variable, and its neighbours given by Olbers (who also appends a diagram), it is evident that his star, which followed 53 Virginis 30′ 55″ in R.A., 20′ 45″ to the south, is No. 12,728 of Oeltzen's Argelander, a star observed 1851, April 24, and noted of the eighth magnitude. For 1876·0 its place is in R.A. 13h. 7m. 32s., and N.P.D. 105° 53′·7.

Approximate mean places for 1797, March 1, of several stars with which Olbers compared the one in question were:—

	Olbers' Magnitude.	R.A.	N.P.D.
		° ′	° ′
(c)	9	194 40	106 6
(a)	7	194 44	105 24
(d)	11	196 15	105 11

The star (*c*) is Lalande 24,421, called by him $8\frac{1}{2}$; (*d*) is L. 24,597, noted 9; but the star (*a*) is not found either in Lalande or Argelander. Its position in Olbers' diagram corresponds to the place above assigned. What is its present magnitude, or is there some mistake about its position?

On April 1, 1796, the supposed variable was considerably brighter than the star (*a*), according to Olbers; in March 1797, much fainter than (*c*) and only slightly brighter than (*d*); he remarked no change in March, April, and May. Bode says, on April 24 and May 12 and 20 of the same year he saw it as a 9·10. In March 1855 it was fully eighth magnitude or 7·7.

THE APRIL METEORS.—As the moon will be absent during the nights of the 19th and 20th of the present month, a watch may be advantageously kept for meteors which are supposed to move in the path of the first comet of 1861 discovered by Mr. Thatcher, of New York, on April 4. At the descending node this comet makes a remarkably close approach to the earth's annual track, the definitive orbit calculated by Prof. Oppölzer, showing that at this point the distance between the two orbits is only 0·00232 of the earth's mean distance from the sun, or 214,000 miles; less, therefore, than the moon's mean distance from the earth. The elements are elliptical with a revolution of 415 years, and this form of orbit we may assume with much probability to have been occasioned by a near approach of the comet to the earth at some distant epoch. The descending node is passed $22\frac{1}{2}$ days before perihelion passage, and to bring the comet into closest possible proximity to our globe, it is necessary that the perihelion point should be passed on May 12. Had this been the case in 1861, the comet would have occupied the following positions on its descent towards the plane of the ecliptic:—

	R.A.	N.P.D.	Distance from earth.
	°	°	
March 24·0	269·2	57·4	0·700
April 1·0	270·3	57·0	0·494
„ 9·0	271·3	57·1	0·281
„ 17·0	285·2	59·4	0·065

The true dimensions of the orbit of this comet will be defined by the following numbers, which are in units of the earth's mean distance from the sun.

Semi-axis major	55·676
Semi-axis minor	10·083
Semi-parameter	1·826
Perihelion distance	0·921
Aphelion distance	110·430

PROF. HUXLEY'S LECTURES ON THE EVIDENCE AS TO THE ORIGIN OF EXISTING VERTEBRATE ANIMALS[1]

IV.

THE crocodiles form the highest group of existing reptiles; they are higher than lizards as a steam-vessel is higher than a sailing-ship; for, while built essentially on the same lines, and exhibiting altogether the same fundamental structure, they are in some respects peculiarly modified, and that always in the direction of greater complexity.

Besides the characters of the skull mentioned in the last lecture, they are distinguished from lizards by having a four-chambered heart, one in which the separation of the ventricle into two distinct cavities is completed, so that, in the heart itself, the blood from the lungs is kept separate from that returned from the body generally. A mixture, however, takes place subsequently, through an aperture between the two aortæ, one of which springs from each ventricle.

Crocodiles are found in Central America, India, Africa, and Australia. Of the many species, the greater number are short-snouted; the fish-eating Gavial of the Ganges, on the other hand, has an extremely long and narrow snout.

All the existing crocodiles are fresh-water or estuarine animals, but, fortunately, this was not the case with the ancient forms, many of which were exclusively marine, seeming, so to say, to take the place, in the sea of their own epoch, of our porpoises and dolphins.

Besides Tertiary species, crocodiles are found in the Chalk, Oolite, Lias, and Trias often in the best possible state of preservation; they therefore extend back to the very commencement of the Mesozoic epoch.

[1] A course of six lectures to working men, delivered in the theatre of the Royal School of Mines. Lecture IV., March 20. Continued from p. 430.

If we had specimens of all known forms of crocodiles, recent and extinct, and set to work to classify them according to their degrees of likeness and unlikeness, we should find that they naturally fell into three series.

In the first of these it would be found that the skull had all the characters mentioned at the end of the last lecture, the posterior nares being small apertures opening into the cavity of the mouth behind the pterygoid bones; the vertebræ would be concave in front and convex behind; the two bones composing the shoulder-girdle, the shoulder-blade or scapula and the coracoid, would be similar in shape, both being long and narrow; in the hip-girdle, the haunch-bone or ilium would be much cut away in front and excavated below, the ischium and pubis being both long blade-like bones; and there would be seven or eight longitudinal rows of bony plates on the back.

In the second set we should find the posterior nares to be much larger and placed farther forwards, immediately behind the palatine bones, the pterygoids not uniting as in the first group. The vertebræ would be slightly hollowed out at each end. In the shoulder and hip girdles there would be no important difference from the first group, with which also the more minute structure of the limbs would correspond closely. A difference would, however, be found in the fact of there being not more than two rows of plates on the back.

In the third series, we should notice certain very striking changes. The posterior nares would be actually as far forward as in a lizard; neither the palatine nor the pterygoids uniting in the floor of the mouth; the vertebræ would be completely amphicœlous or biconcave; the coracoid no longer long and narrow, but expanded and rounded like that of a lizard; the ilium more elongated and without the notch on its lower edge; and the ischium considerably broadened. As in the preceding group, the rows of bony plates on the back would not exceed two.

Thus we should find that the second group held an exactly intermediate place between the first and third, and that the third set, in every respect in which it differed from the normal crocodilian structure, approached to that of lizards.

It is a very interesting point to see how these three groups appear in time. We should find that in the first are included all the Recent and Tertiary forms, and that there are no indications of the type below the later Cretaceous.

The second group would be found to extend from the older Cretaceous down to the Lias; moreover, a careful examination would show that there were lesser modifications among the individual species of a very instructive nature; those from the Wealden, for instance, would be seen to have the posterior nares farther back (*i.e.*, nearer the typical crocodilian position) than those of the middle Mesozoic, and these again than those of the Lias.

The third group would contain exclusively Triassic forms, such as the dragon-like *Belodon* and the *Stagonolepis* of the Elgin sandstones. In this latter formation the fossils are in a very curious condition; after the sand accumulated round the bodies of the Triasssic animals had hardened, water, percolating through the porous rock, completely dissolved out the bones, leaving nothing but cavities. Thus we have only the remains of remains to deal with, but casts taken from the cavities enable us to make out, with perfect certainty, even important characters, although there may be hardly a bone left.

We see then, that our third set of forms is the oldest, our first the youngest, and the study of crocodilian remains seem to show that that has happened in the history of crocodiles, which should have happened, if the theory of evolution be true. Anatomical characters show that crocodiles are a modification of the lacertian type, and to this type the Triassic species, from which we are certainly justified in supposing that existing forms are descended, exhibit a marked approximation.

Still we are very far from knowing the whole story: it is certainly allowable to assume that our third group of crocodilian forms was evolved from a common stock with lizards, but this is as far as the facts of the case will take us at present.

There seems, at first sight, to be something unnatural in speaking of birds and reptiles together, for no two animals can be, to all appearance, more unlike. The wonderfully constructed feathers of the one group, compared with the scutes and scales of the other, the cold blood of the reptile contrasted with the hot fluid which circulates through the vessels of a bird and raises its body several degrees above our own in temperature; the dumbness and general sluggishness of the reptile as compared with the vocal powers and the rapid flight of birds; all these compel us to say, and justly so, that nothing can be more different than the character of the two classes.

Even when we go more into details, similar differences are apparent. The bird has a small head, set on a long flexible neck, and provided with a horny beak in lieu of teeth; its bones are hollow and full of air; its breast-bone, instead of being a small plate of cartilage, is a huge bony plate, usually provided with a large keel for the attachment of the powerful muscles of flight; the fore-limb is of no use in progression on the ground, and, the body having to be supported entirely by the hind limbs, the femora are placed parallel to the long axis of the body, instead of almost at right angles to it as in a reptile, so that the body is well raised from the ground, and a gait the very opposite of a reptile's sprawling waddle is the result.

The scapula and coracoid are not so very different from the corresponding bones in the lower class; the humerus, ulna, and radius, can also be perfectly well identified, but the modification of the distal division of the limb—the part answering to the reptile's fore-paw or to our own hand—is very great. First come two small bones answering to carpals, then three longer ones all united together, which represent the metacarpus, and are followed by the rudiments of the phalanges of the three corresponding digits. In the ostrich two of these three "fingers" are terminated by claws, the use of which it is rather hard to divine, unless the bird uses them for scratching itself, an operation in which a very large portion of the activity of the lower animals is taken up.

The haunch-bone, or ilium, is of enormous size, and extends a long way in front of, as well as behind, the acetabulum; in correspondence with this, a great number of vertebræ are fused together to form a sacrum of sufficient size for the attachment of the ilia and the support of the weight of the body. The ischium and pubis are long slender bones, and the latter, as well as the former, is bent back, so that they both come to lie nearly parallel with the vertebral column.

To allow of the femur taking up its position parallel with the axis of the body, its well-finished globular head is set on at right-angles to the shaft; moreover, its further end has a characteristic notch for the reception of the upper extremity of the fibula. The shin-bone is provided with a large and very characteristic crest for the attachment of the strong muscles of the anterior part of the thigh; its lower extremity is pulley-shaped, and, in a young bird, the pulley-like end, continued into a tongue of bone running up the back of the tibia, can be separated as a perfectly distinct ossification; its shaft also is so twisted that its two ends come to lie in different planes.

Following upon the tibia comes a bone with an easily separable piece at its upper end, and showing signs of a longitudinal division into three separate bones; this is the tarso-metatarsus, and represents the metatarsals and all the tarsals except one—the astragalus—which is represented by the pulley of the tibia. As a rule there are four toes, three of which are turned forwards and articulate with the tarso-metatarsus, while the fourth, the repre-

sentative of our hallux or great toe, is turned backwards and articulates with a small distinct bone.

The heart has four perfectly distinct chambers, so that the pure blood from the lungs, and the impure blood from the rest of the body, are kept quite separate. There is a single aorta which turns to the right side after leaving the heart.

(*To be continued.*)

ON SAFETY MATCHES

THE fact has been known during some years past that the so-called safety matches, which are warranted to ignite "only on the box," can be fired by being rubbed on glass, and as Mr. Preece recently pointed out (NATURE, vol. xiii p. 208), on ebonite. I find that they can be ignited by friction against ivory (I used an ivory paper-knife), steel (a steel spatula, somewhat worn), zinc, copper, marble with the polish worn off, and a freshly-cleaved surface of slate.

The match (or two matches together, for the sake of strength) should be held near the tipped end, and then be rubbed with strong friction, and with a long sweep upon the solid surface. From two to twelve such sweeps may be required before the match ignites, and the result seems to be due to the conversion of mechanical work into heat sufficient to fire the paste at the end of the match, which, I suppose, consists mainly of potassic chlorate and sulphide of antimony.

After a few rubs the match begins to crackle, and then suddenly bursts into flame. A similar result may be obtained by grinding the chlorate in a mortar with a little sulphur or sulphide.

The readiness with which the match ignites by friction depends greatly on the nature of the surface. Lead is too soft, and tin too smooth. The metals produced by rolling have a sort of skin on the surface, over which the match glides without sufficient friction, but if the surface of zinc be rubbed with sand-paper or with a fine file, it becomes active in firing the match. I noticed that the polish of my ivory paper-knife became worn before it acted well. Nor is it very easy to fire the match on glass. A long sweep repeated about a dozen times with considerable pressure seems to be necessary. The two specimens of sheet copper used by me have a sort of grain which is favourable to the success of the experiment. The copper acted equally well whether the surface was dirty or cleaned with dilute sulphuric acid. After rubbing a match ten or twelve times on zinc, without effect, the same match rubbed on copper immediately took fire.

In the case of slate, lead, tin, and some other surfaces, the composition on the match acts as a polish, and thus renders it unfit for ignition. On the other hand, a finely-cut file removes the composition from the end of the match without igniting it.

I have no doubt that many other surfaces might be found on which the safety matches would ignite with greater or less difficulty. Notwithstanding this, the match is still a safety match, although it does not comply with the conditions asserted twice over on the box. It does not ignite readily on any of the surfaces pointed out except copper and marble, but it does ignite with wonderful facility when rubbed against the side of the box, an invention so ingenious that a few words of its history may not be out of place here.

About the year 1850 a gentleman entered the laboratory of King's College, London, and drew from his waistcoat pocket a fragment of a rough-looking red solid, and, placing it in the hands of Prof. Miller, asked him if he knew what it was. It was handed round among those present, but no one had the slightest idea as to its nature, when, to the astonishment of every one, the gentleman said, "It is phosphorus—amorphous phosphorus, discovered by me, Herr Schrötter, of Vienna."

Up to this time, and indeed for some years later, persons engaged in the manufacture of lucifers were subject to a terrible disease, known in the London hospitals as "the jaw disease;" necrosis of the lower jaw induced by constantly inhaling the fumes of phosphorus acid escaping from the phosphorus of the paste with which the matches were tipped.

Ordinary matches made with phosphorus were, during many years, dangerous contrivances. They were luminous in the dark, liable to ignition on a warm mantelpiece, poisonous; children have been killed by using them as playthings; and, moreover, they absorbed moisture, and became useless by age.

But the chief inducement in getting rid of ordinary phosphorus and substituting the new variety was to put an end, as far as possible, to the jaw disease. The red, or amorphous phosphorus, gave off no fumes, had no smell, was not poisonous, and the matches made with it were not luminous in the dark; they did not fire on a warm mantelpiece, did not contract damp, and would keep for any length of time. A manufacturer, in 1851, sent me several samples of matches made with red phosphorus. I found some of these matches the other day, and they were as active, after twenty-five years, as at first.

But here was a difficulty. When the red phosphorus is brought into contact with potassic chlorate a slight touch is sufficient to produce an explosion, in which the red phosphorus reassumes its ordinary condition. Many attempts were made to form a paste, and many accidents and some deaths occurred in consequence. Prizes and rewards were offered by manufacturers and others for a safe paste, or for some means of using the red instead of the ordinary phosphorus, but without success, so that the patent for the manufacture of red phosphorus, which was secured by Mr. Albright, of Birmingham, in 1851, threatened to be of but little value.

At length the happy idea occurred to a Swedish manufacturer not to attempt to make a paste at all with the red phosphorus, but to make the consumer bring the essential ingredients together in the act of igniting the match.

Mr. Preece's suggestion that the ignition of the matches is due to electricity, may be dismissed in the face of the following experiment:—Place a few grains of red phosphorus on a hard surface together with some powder or a crystal of potassic chlorate, when a gentle tap will cause them to burst into a flame. C. TOMLINSON

NOTES FROM SIBERIA

THE following Siberian notes are furnished me by a Polish gentleman resident at Irkutsk. The dates mentioned follow the Old System, as in Russia, and are twelve days behind our own dates. The letter is dated the 10th of February. My informant says:—

"Some time ago Mr. Czckanofski returned from his second expedition to the most northern parts of Siberia by the Olensk River. He went as far as its mouth, and the extraordinarily warm autumn gave him the opportunity to make very interesting explorations. Till the month of September there was no frost nor snow, and the sea not frozen. The same is reported by Mr. Neumann, who returned lately from the Behring Strait. It may be that these exceptional climatical conditions allowed also Mr. Nordenskjöld's entering the mouth of the Jenessei. The exploration in the Achinsk country of a cavern situated now some thirty fathoms above the bed of the river gave to Mr. Tskersky[1] a fine collection of well-conserved fossils of extinct species. Mr. Tskersky occupies himself now with the description of the Tunka Alps, which he believes to be the former boundary of Lake Baikal, as he found there the fossils of the crab and

[1] The Curator of the Museum at Irkutsk.—G. F.

seals.[1] Dr. Dybowsky passed a year on the Ussour River, and brought a beautiful collection of birds, fish, and quadruped skeletons. His descriptions are sent to the Berlin Museum. Now he is occupied upon the Baikal with soundings and observations on the Baikal seals. He wishes to write a monograph on this particular species of seals. This is nearly all that was done last year, as far as expeditions are concerned, in this part of the world."

My correspondent refers me to the proceedings of the Siberian Geographical Society for further details. It is much to be regretted that this publication, as well as the excellent Calendar of Eastern Siberia are so little known, out of Asia. I further learn that earthquake shocks have been felt at Irkutsk on the 4th of September last, at 2.55 A.M., and a slight one on the 4th of January. The first one came from the east. A clock which was secured by screws almost an inch long, was left leaning on one side, and both of the screws drawn completely out of the wall. The Baikal district is the spot in Northern Asia which is most visited by earthquakes.

Since I am on the subject of Siberia, I may mention two facts of considerable interest which I learnt last year. I was told by inhabitants of Jenesseisk that in the regions to the north of that town the compass is of no use during an auroral display. It is not at all unlikely that this should be the case in a country where auroral effects are intense, and the horizontal component of the earth's magnetism is small. The other interesting fact is that Mr. Muller had reached Gauss' Siberian magnetic pole, where he found the needle vertical. This was shortly before I reached Irkutsk. His observations were to be published in the Proceedings of the Siberian Geographical Society. I do not know whether a translation has been published. GEORGE FORBES

Andersonian University, Glasgow, April 4

[1] Lake Baikal is remarkable, among other things for the presence of these marine animals. The seals are grey, and have a very coarse fur. I took a photograph last summer of one which was in the Museum at Irkutsk.—G. F.

THE DUBLIN SOCIETIES

WE have recently referred in several articles to the efforts which are being made to introduce a more satisfactory organisation among the various scientific institutions in Dublin, which have hitherto been independent of each other. It appears now to be proposed not merely to unite museums, but to unite into one body the Royal Irish Academy and the Royal Dublin Society. This project would seem to have originated at a meeting which a deputation from the latter body had with Major Donnelly. It is evident that many difficulties would be removed and many advantages result from the amalgamation of these two societies. Of course the arrangements for such an amalgamation must be carried out entirely by the societies, though it would no doubt tend to forward such a scheme if the societies were assured of the approval of Government, and of such aid towards taking the necessary steps as the Government has in its power to give.

We understand further that there is some possibility of an amalgamation of the Royal Agricultural Society of Ireland with the Royal Dublin Society. It is most desirable that such an amalgamation should be effected, and that the agricultural shows should be removed from the present buildings beside Leinster House to the Phœnix Park.

From a letter which has been published in the Irish papers, it appears that these points have been submitted by Major Donnelly to Lord Sandon, who has informed him that the Government are prepared to aid the amalgamation and to give the necessary space in the Phœnix Park.

Should the amalgamation be effected, it would probably take the form of a new Society with a limited number of Fellows, ordinary members, and an Agricultural Section.

It is possible enough that some of the members of the Royal Irish Academy may object to the proposed change, on the score that they would thus lose caste. We cannot admit the validity of such an objection. The Academy has no doubt done good work, but it has a large number of members on its roll who are no more entitled to any scientific or literary distinction than the general body of the members of the Royal Dublin Society. If, however, the Academy consent to the proposed change, the Fellowship of the new Society would become a high and much-coveted honour, and the reputation of the whole body would be far higher than that of the separate societies is now. As to the objection that the large body of general members are unfit to select Fellows, we think that the Fellows may very well be entrusted with the selection of Fellows; the first Fellows under the new charter might be, say Fellows of Trinity College, Dublin, Professors and ex-Professors of a College or University, and others with similar positions, who should be empowered to choose their successors. There need be no difficulty, while acting with perfect fairness and openness, in choosing for the inner circle and also for the governing body the best men of the new society, men who would make a point of maintaining its honour and dignity. The Royal Irish Academy would thus become, under a new name, a select body of Fellows chosen for their scientific and literary merit; in time, indeed, this fellowship might come to be regarded as an honour little inferior to that of F.R.S.

The union of the societies would remove many difficulties as to ownership of property, and would place at their disposal a much larger amount of funds for scientific and literary work than they at present possess. Indeed, it appears to us that from the union on the proposed basis, nothing but good could result, great benefits to the members, and much greater advantages than at present exist for the promotion of science in Ireland. Since government has promised to aid the United Society as far as possible, we think it would be a pity if any petty spirit of local jealousy should raise obstructions to the accomplishment of a scheme which promises so well for the country.

GERMANY AND THE LOAN EXHIBITION

THE German Committee for the London Loan Exhibition of Scientific Apparatus has addressed a report to the Crown Prince and Crown Princess of Germany on the success of their efforts. It results from this document that 311 German exhibitors will be represented by 2,492 objects. The 19 classes will be represented as follows:—

1.	Arithmetic by	6 exhibitors and	11 objects.
2.	Geometry by	13 ,, ,,	35 ,,
3.	Measurement by	59 ,, ,,	126 ,,
4.	Kinematics by	10 ,, ,,	308 ,,
5.	Molecular Physics by	23 ,, ,,	33 ,,
6.	Sound by	10 ,, ,,	24 ,,
7.	Light by	35 ,, ,,	118 ,,
8.	Heat by	19 ,, ,,	41 ,,
10.	Electricity by	32 ,, ,,	194 ,,
11.	Astronomy by	25 ,, ,,	78 ,,
12.	Applied Mechanics by	13 ,, ,,	64 ,,
13.	Chemistry[1] by	32 ,, ,,	389 ,,
14.	Meteorology by	18 ,, ,,	49 ,,
15.	Geography by	29 ,, ,,	110 ,,
16.	Geology by	22 ,, ,,	118 ,,
17.	Mineralogy by	19 ,, ,,	39 ,,
18.	Biology by	54 ,, ,,	289 ,,
19.	Educational Collections by	5 ,, ,,	441 ,,

The space claimed by the exhibitors will be 109 square metres floor, 442 square metres repositories (tables, &c.), 299 square metres wall. Considering that two months had to suffice for bringing together this collection, that manu-

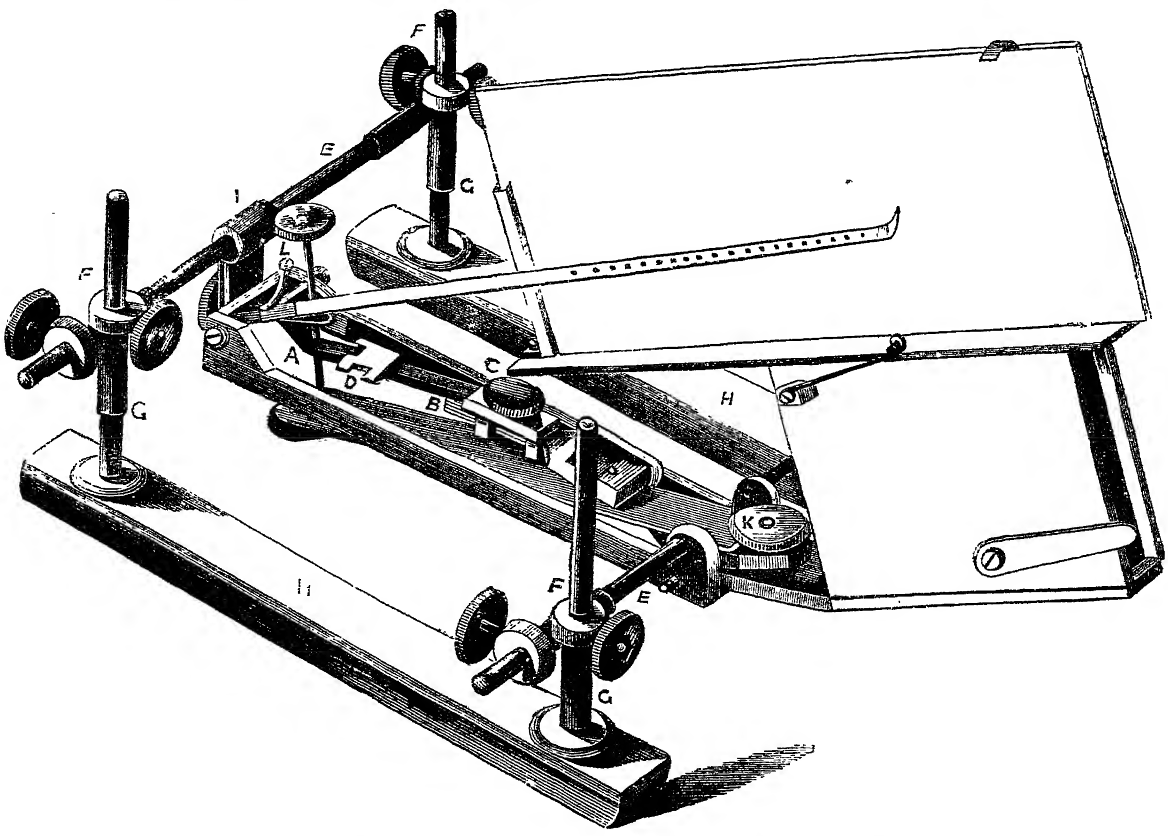
[1] Exclusive of the collective exhibition of the German Chemical Society, which will represent about 40 exhibitors with 300 objects.

facturers are beginning to feel indifferent with regard to exhibitions, that the Vienna Exhibition in the past and the Philadelphia Exhibition in the present years, have been absorbing their energies, the Committee think that they have reason to be contented with the results obtained. This view is strengthened by comparing the above numbers with those of 127 exhibitors only who represented German science at Vienna. The Committee express themselves greatly obliged for the assistance given by the Lord President of the Council of Education, the Duke of Richmond and Gordon, the Vice-President, Viscount Sandon, the Director of the South Kensington Museum, Mr. Cunliffe Owen, and to the Government and Officers of the German Empire and of Prussia, notably to the Ministers of Education, Dr. Falk, of Commerce, Dr. Achenbach, of War, General von Kamecke, of Marine, to the head of the General Staff, Count Moltke, to the Postmaster-General, Dr. Stephan, and also to the Royal Library, to the Royal Academy of Science, and to the German Chemical Society. The Committee conclude by claiming the assistance of the German Empire for the production of a systematic and critical report on the scientific treasures of all nations that will be exhibited in London.

ON A MODIFIED CARDIOGRAPH

DR. A. L. GALABIN, whose investigations with the sphygmograph and cardiograph we have had the opportunity of noticing on former occasions (*vide* NATURE, vol. xii. p. 275), has introduced a modification of the cardiograph, a woodcut drawing of which, through the kindness of the Council of the Royal Medico-Chirurgical Society, we are able to reproduce from their "Transactions."

The cardiograph of Marey is too well known to require description; suffice it to say that it depends for its action on the transmission through air-filled tubes of movements from one stretched elastic membrane to another. In it, therefore, errors originating in the tubes are introduced; and these, from practical experience, are found to be considerable. More than one physiologist has obtained far more satisfactory "cardiograms" by applying the sphygmograph, which was originally constructed by its inventor—M. Marey—for the purpose of recording the movements of the pulse at the wrist, upon the chest-wall, in the intercostal spaces. This instrument, when thus



applied, reproduces in a most faithful manner the movements of the chest-walls as there produced by the subjacent heart in action; and in the healthy subject any accessory apparatus is rarely needed for the satisfactory production of the tracings.

In many pathological conditions, and in the healthy subject when the cardiac movements are more than ordinarily powerful, the movements of the heart are transmitted to the neighbouring ribs, on which the sphygmograph has to be supported, as well as to the more yielding intercostal tissues. Under these circumstances it is far better to employ, as supports for the instrument, more fixed points, which must, from the nature of the chest-wall, be at some distance from the centre of cardiac movement. Dr. Galabin's apparatus supplies us with the means needed. It is an expanded framework constructed in a manner which allows of its being firmly applied to a considerable expanse of the irregularly-shaped chest. From the drawing its principle can be best understood (See Figure).

In the middle of the figure the sphygmograph is seen. It differs from M. Marey's original in one or two minor details, which are decided improvements. The most important of these is that the brass bar A B, on which the

knife-edge by means of which the recording lever is set in motion is fixed, can be varied in length; and this makes it possible to vary the magnifying power of the lever, because the distance of the knife-edge from its axle can be changed. Such an addition has always been a desideratum, even in the wrist sphygmograph. The screw, C, clamps the two component parts in any desired position. A second reserve knife-edge, D, can also be turned up to replace the ordinary one, A, when the cardiac action is extraordinarily forcible. By the screw, K, the compress-spring is fixed. L is the secondary spring, which prevents the recording lever from quitting the knife-edge; it can be thrown out of gear when not required.

The supporting bars are seen at H H; they replacing the side-lappets of the original instrument. On them are fixed uprights, G G G, on which again are attached by screw-clamps two transverse bars for the suspension of the sphygmograph. That to which the clock-work end is joined can only be moved upon the uprights with which it is connected. The other has an additional sliding-piece, I, that allows of the screw-pad portion being independently raised or lowered in a hinged manner.

That this suspending stage will prove of great service in the study of the heart's action there can be no doubt. The presence of the large number of movable centres must, however, render its adjustment somewhat difficult. It will be seen in the figure that the recording plate above the watch-work is of considerable depth. We have found, practically, that it is *never* advantageous to allow the oscillations of the lever to reach nearly so great an amplitude as this will permit; and it is known by all that it is very important that the average level of the lever's tracing should never be far above that line which is perpendicular to the tangent of the circle formed by the lever in its movements, at the point where the two cut one another.

Whilst on the subject of Dr. Galabin's cardiograph and sphygmograph work, we may incidentally draw attention to a point in a paper by him in the January number of the *Journal of Anatomy and Physiology*. Dr. Galabin there comments on Mr. Garrod's law respecting the length of the cardiac systole as it appears in the arterial system—that it is constant for any given pulse-rate, and varies as the cube root of the rate. He remarks, "I have found the length of the systolic portion of the pulse-curve to deviate somewhat considerably from that deduced from the equation. . . . It appears to be approximately true in normal pulses." Would it not have been better if Dr. Galabin had given a larger number of examples—he having confined himself to two, of which one is pathological? In the paper in which the law was announced, the agreement of the measurements with the requirements was very close, and others have been published since, even more satisfactory; it has also been indicated by its author that a pathological condition, like anæmia (the instance taken), is just such an one as that in which a deviation might be expected. Mr. Edgar Thurston, of King's College, has recently read a paper before the Medical Society of that School, which is quite in confirmation of the law as originally stated, from a considerable number of observations on *healthy* subjects.

PHYSICAL SCIENCE IN SCHOOLS

DR. WATTS quite puzzles me. I can see no contradiction between the passages from my essay of 1867 and my letter of 1876, which he silently places in juxtaposition. What I said in 1867 was (p. 261) that "science should be introduced into a school, beginning at the top and going downwards gradually to a point which will be indicated by experience." What I say in 1876 is that experience shows, as far as I can judge, that it is not generally wise to go down very far; that one soon comes to a point at which the loss in teaching science counterbalances the gain. I am quite as sure as ever I was of the value of science in schools, in its right place.

I think that those who advocate the teaching of science to young boys scarcely realise the difficulty of establishing their ground. Some, like Prof. Roscoe (p. 387), admit, when pressed, that it is a question which experience alone can decide, and that they have not had that experience. Liebig, to whom Mr. Gerstl refers (p. 431), was speaking of a different class of schools, in which boys must pick up some useful scientific facts early or not at all. Prof. Henslow's experience is of the same kind. Other philosophers, charmed with the bright intelligence of children when talked to by a Faraday or a Frankland, straightway pronounce an opinion on the relative value of science and classics and mathematics in the early part of a liberal education,—on somewhat insufficient grounds.

The question that this discussion began with was the merits or demerits of the Certificate Examination, in so far as it affected science in schools. That seems to be settled. We have drifted now into a different and most useful discussion on the results of experience in the early teaching of science. The question is this. Given that boys are going to remain under a system of liberal education till eighteen or nineteen, at what stages is it shown by experience that it is wise to introduce the different sciences? It is a question of the *comparative* value of different studies at different ages, not only of what may best be learnt, but of what may least injuriously remain unlearnt, at different ages; and those teachers speak with real weight who can institute such a comparison; men who have watched the processes by which young boys learn different subjects. A man who teaches science only cannot institute such a comparison. He can only say, "I *do* teach young boys something of chemistry and botany, and they *do* gain something." One who teaches mathematics also is so far better off that he can say, "Young boys are more (or less) attentive, active-minded, diligent, when they are doing arithmetic, than when they are at a lesson on physical geography; and they are more (or less) incapable in later years of recovering from the ill effects of neglected arithmetic than of neglected physical geography." One who teaches classics also (as I do for more hours a week than I teach physical science) has wider grounds still for forming a comparison.

Nothing that I see young boys do is as efficient as Latin in completely occupying their minds with perpetually recurring problems which tax attention, memory, judgment, taste. It is quite interesting enough not to be too tiresome. The problems are easy and varied, and the solutions certain and satisfactory. The same sort of young boys who will work hard and cheerfully over a bit of Cæsar or a Latin exercise seem to be a good deal bored by a lesson on physical geography, think botany rather nonsense, and submit silently to the hopeless unintelligibility of "matter and motion." The very same boys will as a rule enjoy an arithmetic lesson and work happily at their practical geometry, or, when well handled, their Euclid. Hence, if I wanted to train up a boy for a scientific career, I would not begin very early with science, but wait till he was thirteen or fourteen.

I admit that the experience of some others is against me. Mr. Tuckwell (p. 412) speaks warmly, and pronounces my opinion to mean nothing more than that I myself have failed to teach science to young boys. This is a mistake. It means that I have seen the work of others, here and elsewhere. It means not an absolute failure, but a comparative failure, as explained above. It means a summary of the opinions of a considerable number of other men. Mr. Wyles (p. 455) is against me, although he has "never been satisfied with his science teaching." Mr. West (vol. xiii. p. 48) is against me, and his opinion

is a valuable one. But it must be remembered that it is not a personal question, which admits of the simple solution that Mr. Tuckwell can teach science and that Mr. Wilson cannot, but a general one: can science be taught to young boys by the rank and file of science teachers, who are, or will be when they are numerous, neither more nor less able and enthusiastic than the rank and file of classical teachers, very average sort of people? I do not doubt for a moment that my old pupil West can teach little boys science with great advantage, but I doubt very much whether there exist fifty Wests as schoolmasters at any one time in England; and to justify making his practice universal we want to be certain of finding five thousand or fifty thousand such men as teachers. Let it be remembered that very dry and dull men teach classics, and not very badly, while the same men would teach a science class nothing, or worse than nothing.

I wish Dr. Farrar, of Marlborough, would give us his opinion on this whole question. He has had unusual opportunities for forming an opinion and has, no doubt, used them; and I do not know to what conclusions he has arrived.

Mr. Gerstl's proposal to teach facts only—*facts* in italics—is truly fearful to me. I fancy an honest stupid man, like some I know, teaching conscientiously what he considers the *facts* of chemistry or botany, or mechanics; and selecting a book the counterpart of Page's "Advanced Text-book of Geology," or Nicolay's "Physical Geography," bristling with *facts*. The facts of botany, in the hands of most teachers, would be a dreary list I suspect. Mr. Gerstl may teach facts alone successfully, but could the rank and file of our profession do the same?

I will most willingly admit, on the contrary, and maintain, that there exists an early science teaching that is at once useful and well-timed: the excitement and gratification of disinterested curiosity about nature; it is to do for a class, if possible, what an intelligent and encyclopædic father would do for an intelligent child. But how difficult this is for bored and weary schoolmasters! It is so much easier to tell them to get up pp. x to y in Oliver or Ansted.

One and only one English book do I know that might almost make a stupid man teach one science well; and that is Mrs. Kitchener's "A Year's Botany" (Rivington's). That happily does not teach facts only; but is the expression of the method of a first-rate teacher in such a form as to enable any one to follow it. And yet I tremble as I mention it, for fear some class of tinies shall be ordered to get it and learn the first six pages for their first lesson in botany.

To conclude, therefore, for I will write no more on this matter, what I advise is to interest young boys in science by conversation, by informal teaching, by Natural History Societies, by encouraging collections, aquariums, &c., but not, except in the case of having that rare thing, a genius for the science master (by which I mean a genius for being a master, not a genius for science), to make science a regular subject of class teaching in the lower forms; but to teach the other subjects *well*. Then to bring in science as compulsory on all, first as Physical Geography and Astronomy or Botany, then as Chemistry with laboratory work, and Physics; and after two or three years to let boys choose their own lines. Some will drop it, others will pursue it further. This is one opinion, in brief, on the right place of science in liberal education. Now let us hear what others have to say.

Rugby, April 8 JAMES M. WILSON

NOTES

As might have been expected, Lieut. Cameron met with an enthusiastic reception from a large and distinguished audience at the meeting of the Royal Geographical Society in St. James's Hall on Tuesday night. The hall was crowded, and the Duke of Edinburgh occupied the chair, surrounded by many eminent geographers. His Royal Highness introduced Lieut. Cameron in a few appropriate and appreciative words. The distinguished explorer gave a narrative of his journey from Zanzibar to the West Coast of Africa, going over ground which is no doubt already pretty familiar to our readers. Sir Henry Rawlinson gave a very clear summary of the work which Lieut. Cameron has accomplished. "He has not been a mere explorer," Sir Henry said, "one of those travellers who carry their eyes in their pockets. He always kept his eyes well about him, and the observations which he made, both of an astronomical and of a physical character, are of extraordinary value. The register of observations which he has brought home, and which are now being computed at the Observatory at Greenwich, promise to be of a most important character. They are astonishingly numerous, elaborate, and accurate, and I have great expectation that one consequence of computing those observations will be that we shall have a definite line laid down from one sea to the other across 20 degrees of longitude, which will serve as a fixed mathematical basis of all future geographical explorations of Equatorial Africa. Among the minor objects achieved by Lieutenant Cameron must be noticed his circumnavigation of the great lake Tanganyika and his discovery of the outlet whereby that lake discharges its waters into the great river Lualaba. Another very important matter is the identification as nearly as possible, not absolutely proved by mathematical demonstration, that the Lualaba is the Congo. One of the main objects of the expedition was to follow down the course of that river so as to prove or disprove the identity of the Lualaba and the Congo. Lieut. Cameron was not able, as he explained to you, to carry out that scheme in its entirety, but he collected sufficient information on the spot to render it a matter, not of positive certainty, but in the highest degree of probability, that the two rivers are one and the same. Another great discovery of his is the determination of a new river system between the valley which he followed of the Lolame, and the scene of Dr. Livingstone's discoveries. This valley, which consists of a large river running through a series of lakes, forms, as he fully believes, and as I also believe, the course of the true Lualaba. The observations which he has furnished respecting latitude, longitude, and elevation, amount to the extraordinary number of nearly 5,000; and he took as many as 130 or 140 lunar observations on one single spot." The Geographical Society has only done its duty in awarding to Lieut. Cameron "the blue riband of scientific geography," its principal gold medal of the year.

THE rules of the French Geographical Society strictly forbid the presentation of a prize to any explorer who has not published the narrative of his discoveries. For this reason the motion for granting a medal to Lieut. Cameron at the anniversary meeting this year, was lost. But in the report and the addresses delivered on that occasion, the admiration of the Society was emphatically expressed. The great medal for 1877 will be granted to Lieut. Cameron, we believe, if the necessary condition of publication shall have been complied with.

THERE was a large gathering last Wednesday evening at the Royal Society Conversazione, which passed off very successfully. One of the most attractive features of these meetings is the instruments and apparatus exhibited; in this respect last Wednesday's meeting was quite equal to any former one. A large proportion of the objects exhibited were connected with Mr. Crookes's recent experiments on light. Among these were the following:—(1) The Torsion Balance. (2) The Turbine Radiometer: (3) Radiometer with the vanes blacked on both sides, showing rotation in either direction according to the way the light falls on them. (4) Radiometer showing the very small amount of residual air which is present. (5) Radiometer show-

ing rotation of the glass envelope when the vanes are held fixed in space. The radiometer carries a magnet on its arms, and is floated on water so as to be free to move. (6) Radiometer having inside it a platinum spiral. (7) Radiometer with one vane counterpoised by a mirror, showing method of keeping the steel point from falling off the cup. (8) Radiometer constructed of metal, showing reverse movement on cooling. (9) Bar Photometer, showing the method of balancing one light by another. (10) Heat Engine: A Turbine Radiometer, having ice below and hot air above; working by difference of temperature. Connected with this subject, Prof. Osborne Reynolds and Dr. Schuster exhibited various apparatus:—(1) Dr. Schuster's experiment, showing that the force discovered by Mr. Crookes reacts on the vessel in which the vacuum is. (2) An experiment, showing that apparently no part of the force is referable to radiation. (3) An instrument to show that the force acts in a direction perpendicular to the hot surface. (4) A photometer which measures the heating effect of light. Among other objects exhibited were:—A series of four Rheotomes, constructed and exhibited by Mr. Apps; Fossil Elephant Bones, found near London, exhibited by Prof. Tennant; New method of measuring the position of Absorption-Bands in Spectra, and Specimens of Pigments from Human Hair, illustrated by drawings, exhibited by Mr. H. C. Sorby, F.R.S.; New Form of Wave Apparatus, invented and exhibited by Mr. C. J. Woodward; Micro-Geometric Pen, and Medical Battery, with De La Rue's (modified) Chloride of Silver and Zinc Elements, exhibited by Tisley and Spiller; Dr. Siemens exhibited his Bathometer recently described in NATURE, and an Attraction Meter, an Instrument by which the attraction of Masses is demonstrated; Mr. Spottiswoode exhibited the largest pair of Nicol's Prisms yet made, and Prof. Tyndall Infusions exposed to Self-cleansed Air; Mr. J. Browning exhibited a large number of beautifully-constructed apparatus, and Mr. W. F. Stanley a Chronobarometer and Chronothermometer, new instruments for registering Atmospheric Temperature and Pressure; Edison's Electric Pen, exhibited by Mr. T. D. Clare. Altogether the objects exhibited were varied and of great interest.

AT a meeting of chairmen of sections for organising the conferences in connection with the approaching Loan Collection of Scientific Apparatus at South Kensington which was held on the 10th inst., it was resolved that the conferences should be held on the following dates:—Physics (including Astronomy), May 16, 19, and 24; Mechanics (including Pure and Applied Mathematics and Measurement), May 17, 22, and 25; Chemistry, May 18 and 23; Biology, May 26 and 29; Physical Geography, Geology, Mineralogy, and Meteorology, May 30, June 1 and 2. It is proposed that addresses should be delivered on special subjects, and that the more important instruments exhibited should be described and discussed.

A MEMORIAL has been forwarded to the Prime Minister on the subject of University reform at Cambridge. It is signed by eighteen out of the thirty-four professors, and the Master of Trinity, eighty-three resident Fellows, twenty-nine University officers, lecturers, &c., have appended their names. The memorialists call the Prime Minister's attention to the following points contained in a memorial addressed to Mr. Gladstone three years ago:—"1. No fellowship should be tenable for life, except only when the original tenure is extended in consideration of services rendered to education, learning, or science, actively and directly, in connection with the University or the Colleges. 2. A permanent professional career should be as far as possible secured to resident educators and students, whether married or no. 3. Provision should be made for the association of the colleges, or of some of them, for educational purposes, so as to secure more efficient teaching, and to allow to the teachers more leisure for private study. 4. The pecuniary and other relations subsisting between the University and the Colleges should be revised, and, if necessary, a representative Board of University Finance should be organised." The memorialists then go on to express their conviction that, in the interest of science, learning, and education, the reforms specified are urgently required, and the hope that they will be distinctly recognised in any Bill that may be proposed in reference to this University.

WE learn from the *Times* that the following are the names of the fifteen candidates for the Fellowship of the Royal Society selected by the Council to be recommended to the Society for election. The day fixed for the election is June 1:—Captain Abney, H. E. Armstrong, Rev. W. B. Clarke, J. Croll, E. Dunkin, Prof. Erichsen, Dr. Ferrier, Colonel Lane-Fox, A. H. Garrod, R. B. Haward, C. Meldrum, E. J. Reed, Prof. Rutherford, R. Swinhoe, and Prof. Thorpe.

WE are much pleased to hear that Lord Walsingham has been appointed a trustee of the British Museum. Lord Walsingham is known to all entomologists as a most zealous collector of and authority upon Microlepidoptera. There being at present but one true biologist among the fifty trustees, the addition of a working naturalist will tend to place the department on a more satisfactory footing.

THE Committee of the German African Society has decided upon making another attempt to explore Central Africa from the West Coast, under the direction of the African traveller, Herr Mohr.

WE understand that Mr. Henry Whitely, jun., so well known for the natural history collections which he has made in Peru, who has recently returned to England, is again about to visit that country, and proposes on this occasion to explore the more northern portion of the Republic. His agent in this country is his father, who resides at 28, Wellington Street, Woolwich.

WE have received the prospectus of "A Monograph of the Cinnyridæ, or Family of Sun-birds," by Capt. G. E. Shelley, F.Z.S., the author of "A Handbook to the Birds of Egypt," &c. The work is to be issued in quarto-sized guinea parts, about twelve in number, each containing ten plates. The plates will be from the pencil of Mr. Keulemans; and the whole will be published as rapidly as their proper execution will permit. The author has, for some time past, been engaged in collecting Sun-birds, and has taken the opportunity of studying them mostly in a state of nature in both Western and Southern Africa.

IT is stated that Prof. Andrews of the Queen's College, Belfast, will probably be President of the British Association in 1877.

DR. JAMES RISDON BENNETT, F.R.S., has been elected President of the Royal College of Physicians, London.

THE April number of the *New Quarterly Magazine* contains, among other articles of general interest, a paper by the Hon. W. H. Drummond, author of "The Large Game of South Africa," on some incidents of African travel.

"ON opening his letters last week," the *British Medical Journal* states, "Prof. Huxley found in one of them a cheque for one thousand pounds, sent by Mr. Thomason, of Manchester, in the name of his lately deceased father, who was a great admirer of Prof. Huxley, and highly appreciated his great achievements in furtherance of our knowledge of the science of life."

WE have much satisfaction in noting that General Myer, Washington, U.S., has resolved to publish, in the *Bulletin of International Meteorological Observations*, the barometrical observations made at all stations 1,000 feet high and upwards, in two columns, one column giving, along with the height, the results reduced to 32° and corrected for instrumental errors only; and

the other column giving the same reduced to sea-level. This mode of publishing the observations will, it is evident, furnish the materials for the discussion of important questions of an international character, which could not be attempted if the observations at the higher stations were published only as reduced to sea-level pressures.

IN No. 13 of the *Journal d'Hygiène*, Dr. de Pietra Santa urges with well-timed earnestness the importance to medical men of keeping steadily in view the two-fold function of climatology, which is, in the first place, to collect, by means of accurate instruments and simple methods, regular meteorological observations; and in the second place, to observe and study carefully the influence of these phenomena in their physiological and pathological relations. In the latter case the attention must be directed to types and sequences of weather which meteorologists have scarcely yet made subjects of investigation.

M. BALARD, whose death we announced last week, was born at Montpellier, Sept. 2, 1802. When quite young he manifested a strong passion for reading and study. He was early attracted to chemistry and physics, and while still young was made assistant *préparateur* and then *préparateur* in chemistry to the Faculty of Sciences. At the age of twenty-four years he discovered the element Bromine, and about 1833 was appointed Professor of Physics to the Montpellier School of Pharmacy and Professor of Chemistry to the Faculty of Sciences. He manifested great perseverance and energy in his researches on the utilisation of sea-water for obtaining various saline bodies, and it was while at Montpellier as professor that he made his fine experiments on hypochlorous acid and amylic alcohol. In 1843 he succeeded M. Thénard at the Sorbonne, and in 1846 he was, besides, appointed Superintendent of Lectures at the Upper Normal School. In both positions he acquired a high reputation for his solid instruction and his eminent qualities as a professor. In 1854 he was appointed Professor of General Chemistry at the Collége de France, a post which he held till his death. He shortly after quitted his position at the Sorbonne to become Inspector-General of Superior Education. In this capacity he never lost an opportunity of impressing upon teachers the great importance of introducing experimental science into schools; the want of apparatus he considered no difficulty, as for such simple experiments as are required in a school, the teacher, he thought, might easily devise his own apparatus. In 1846 he was made a member of the Academy of Sciences, and other well-deserved honours were awarded him. M. Balard's efforts and discoveries were mainly directed to the economic applications of science, and in this respect he has done much valuable work; and in the future his researches in the utilisation of sea-water may probably turn out to be of even greater practical value than they have hitherto been. M. Balard was a man who made many friends, was warm-hearted and benevolent, and was loved and respected by all who knew him. He has left no written work behind him, but his personal influence in the advance of science in France has been great.

MR. TORRENS has given notice that on April 24 he will ask the Prime Minister if the Government will give effect to the report of the Civil Service Commissioners recommending an improvement in the condition of the staff of the British Museum.

WE are glad to know that the idea has been broached in New Zealand and Australia, though in a very quiet way, of a union between the various Australian colonies for the prosecution of Antarctic exploration. The idea seems to have been suggested by the action of the mother-country in sending out the Arctic expedition, and we hope it may grow and take substantial shape. It seems to us that it would be a very proper and creditable thing for the Australian colonies to take up Antarctic exploration as their special department.

A CORRESPONDENT, Mr. F. Green, writing from Cannes, France, states that on the 8th instant, for the first time this year, he heard the Cuckoo in a valley amongst mountains sixteen miles to the westward of that place. The first time last year that he heard it in the same neighbourhood was on the 10th of April.

ON April 2 at 5.55 A.M., an earthquake was felt at Berne. Two movements took place from east to west. The duration at was two seconds; doors were opened, and church bells were rung by the shocks. In Neufchatel a strong detonation was heard; the oscillation was very strong in the lowest part of the city, and clocks struck the hour before the appointed time. Persons who were in the streets declared that warm wind was blowing for some seconds. A few hours afterwards a rain-spout occurred near Mainz, in Rhenish Hesse. A number of houses were struck by a thunderbolt and ignited, many others were flooded by the water falling from the mountains, and people drowned by an instantaneous flood.

THE additions to the Zoological Society's Gardens during the past week include two Chestnut-backed Colies (*Colius castanonotus*) from the River Daude, W. Africa, presented by Mr. Henry C. Tait; a Sclater's Muntjac (*Cervulus sclateri*) from China, presented by Mr. W. H. Medhurst; a Mandrill (*Cynocephalus mormon*), two Yellow Baboons (*Cynocephalus babouin*), a Sooty Mangabey (*Cercocebus fuliginosus*), a Monteiro's Galago (*Galago monteiri*), an African Civet Cat (*Viverra civetta*), a Servaline Cat (*Felis servalina*), a Banded Ichneumon (*Herpestes fasciatus*), a Senegal Touracou (*Corythaix persa*), an Angolan Vulture (*Gypohierax angolensis*), a Marabou Stork (*Leptoptilus crumeniferus*), three Broad-fronted Crocodiles (*Crocodilus frontatus*), from W. Africa, presented by Lieut. V. S. Cameron; two Secretary Vultures (*Serpentarius reptilivorus*), from S. Africa, deposited; three Wild Boars (*Sus scrofa*), born in the Gardens.

EXPERIMENTAL RESEARCHES ON THE EFFECTS OF ELECTRICAL INDUCTION, FOR THE PURPOSE OF RECTIFYING THE THEORY COMMONLY ADOPTED[1]

II.

THE physicist Munck, of Rosenschöld, in his memoir on electrical induction, and on the dissimulation of electricity,[2] concludes that the opposite electricity of the inductor ought to be regarded as bound, since it is connected with the same inductor and cannot be discharged by the induced body.

M. Riess continues to criticise Lichtenberg.[3] He unwittingly admits the existence of dissimulated electricity, since he says "that inductive electricity remains in part dissimulated." He afterwards says, "What has been published on the subject of *bound, latent, dissimulated* electricity has had a pernicious effect upon the science." But if I am not deceived, it is quite the opposite way, as will be seen from my experiments, by which all the objections urged by Riess against the new theory of electrical induction, published by Melloni and verified by me, are overthrown in the clearest possible manner.

Wullner says,[4] "The principal mistake made by Faraday, and on which his reasonings are based, is the hypothesis that induced electricity of the first kind has not the power of acting in an outward direction. It is true that the illustrious English physicist does not explicitly state this hypothesis; but without it his experiments lose all their value." Then according to Wullner, the absence of tension in induced electricity of the first kind is implicitly admitted by Faraday. We shall see that my experiments prove how little evidence there is of tension.

Verdet is not deceived[5] when he adduces the contradiction into which the physicists fall who deny that induced electricity of

[1] An Exposition of the Two Theories of Electrical Induction. By M. Paul Volpicelli. Continued from p. 438.

the first kind is devoid of tension, when they treat of the experiment known as the induced cylinder. Yet the same physicists, Verdet says, admit this want of tension when they treat of the plate condenser, in the instrument known as Volta's condenser, as if these two experiments were not identical. It is clear, he says, that a similar restriction of the same hypothesis is not established, and that if there be dissimulated electricity upon two conducting discs placed near each other, it ought also to exist, although in a less proportion, on two cylindrical or spherical conductors, such as are ordinarily employed in experiments. All this is confirmed by De la Rive;[1] "the experiments of Melloni," he says, "appear to me to account for these anomalies in a satisfactory manner."

In Gehler's Vocabulary[2] we read that Munck, agreeing with Plaff, did not admit the theory of Riess.

Prof. Tyndall thus expresses himself on the subject under discussion[3]:—"When an insulated conductor is under the influence of an electrified body, its repelled electricity is free; but its attracted electricity is held *captive* by the inducing electrified body. If for a moment we put the induced inductor into communication with the earth, its free electricity is dissipated; and if we remove to a distance the inducing electrified body, the *captive* electricity becomes *free*, and is distributed over the surface of the induced conductor." This manner of conceiving the phenomenon of electrical induction agrees perfectly with the new theory of Melloni, which, we maintain, satisfactorily explains the same phenomenon.

Finally, Melloni communicated to the Paris Academy of Sciences[4] (July 24, 1854) his ideas on electrical induction, and maintained, adducing all his reasons in support, that there was ground for amending the theory of induction commonly adopted, that it must be admitted that induced electricity of the first kind did not possess tension, and that the homonym of the inductor is found on every point of the induced body, including the extreme point nearest to the inductor.

After having given this brief but complete *résumé* of the various opinions which have been enunciated on the question, showing that there have never been wanting eminent physicists to maintain that induced electricity of the first kind is entirely devoid of tension, I shall now recount my own observations and experiments, by which, if I am not mistaken, I have proved the truth of Melloni's theory of electrical induction.

EXPERIMENTS.—The experiments I am about to describe should be made when the air is sufficiently dry, as then only are the results perfectly satisfactory.

First Experiment.—Upon the conducting cylinder, induced and insulated, the following five facts are proved:—1. On the same cylinder the two opposite electricities exist without neutralising each other. 2. If the extremity of the cylinder nearest to the inductor is put into communication with the earth, it is *only* the homonym of the inductor which is dissipated and not at all the opposite electricity. 3. Of the two kinds of electricity which are in the cylinder, the homonym of the influent *alone* is dissipated by contact with the air. 4. Points applied to the extremity of the cylinder nearest to the inductor allow only the homonym of the inductor to escape and not at all the opposite electricity. 5. Induced electricity of the first kind is not transferred from the induced body to the inductor, but the electricity of the inductor may certainly be transferred to the induced body.

These five experimental facts cannot be logically explained by the old theory of electrical induction, but only by the new, showing that induced electricity of the first kind does not possess tension, *i.e.*, that it is entirely dissimulated, and that induced electricity of the second kind, *i.e.*, the homonym of the inductor, is entirely free on all points of the induced object.

Second Experiment.[5]—In the communication referred to in the note are analysed the phases of divergence produced in the gold-leaf electrometers applied to the extremity of the insulated induced body nearest to the inductor. The same phases were obtained by means of two simultaneous inductions, the one principal, which came from the inductor, the other secondary, which came from the analyser.

On this ground it is concluded that these phases, when they are fairly interpreted, prove that the homonym of the inductor exists also on the extremity indicated, and that on this account the induced electricity has no tension. In the same experiment it was seen how these phases may be misleading, if we do not examine carefully the simultaneous effects of the two inductions indicated. The explanation of this experiment allows a much greater development than that of Melloni, published by M. Regnault in the "Comptes Rendus," t. 39, p. 177 (July 24, 1854).

Third Experiment.—When, into the inductive sphere of an electrified body, *a*, is introduced,[1] with the necessary precautions, another insulated body, *b*, the electricity of the inductor, *a*, always attracts and completely dissimulates the induced body, *b*, the opposite electrical condition, expelling the homologue, and rendering it completely *free*. But this is not all. There is another fact, which has not yet been indicated, viz., that if we bring close to or remove away from the inducing body, *a*, another body, *c*, then part of the dissimulated electricity in the induced *b* becomes *free* in the former case, while in the second case it increases in *b*, at the same time that the opposite condition is developed in it.

In the paper above cited all the experiments confirming this result are given, from which we conclude that the induced electricity of the first kind does not possess tension.

Fourth Experiment.—The first experiments made for the purpose of discovering if electrostatic induction can be effected in curved lines, are due to the illustrious Faraday, who, in one of his latest papers, says that by his experiments he believes he has established the possibility of this induction; perhaps the facts which I have discovered, and which are completely verified when the atmosphere is dry, may establish its certainty. These experiments, by which is proved the existence of curvilinear induction, will be found described in "Comptes Rendus," t. 43, p. 719.

Fifth Experiment.—This fifth experiment[2] contains an account of six considerations and of five experiments, by means of which it is shown that induced electricity of the first kind does not possess tension, and that the induced insulated cylinder shows at all points the existence of the homonym of the inductor.

Sixth Experiment.—In this[3] are described several experiments which show the existence of curvilinear induction, and prove at the same time that the separation of the gold-leaf electrometers, applied to the extremity of the induced body furthest from the inductor, is produced principally by this influence, and to a very small extent by the homonym of the inductor.

Seventh Experiment.—In this[4] is shown, in a different manner, that induced electricity of the first kind has no tension, and that on any point of the induced body there is always found the homonym of the inducing, not excepting the extremity nearest to the inductor, provided that the proper means is employed, as described in the communication referred to.

Eighth Experiment.—In this[5] are analysed the objections made by M. Riess to some of my experiments on electrical induction, and the doctrine of Melloni on this subject is confirmed by other facts. The conclusion is that the objections of M. Riess are not justifiable, and that if this eminent physicist had repeated the experiments which he criticises, he would have found them to be genuine, and would not have declared them to be inexplicable. It is now more than sixteen years since I made this reply to M. Riess, always communicating other experiments bearing on the same point; but, so far as I know, he has raised no other objections to the theory of Melloni.

Ninth Experiment.—In this communication[6] eight reasons are adduced to show that induced electricity has no tension. The same reasons do not hold good on the old theory, while Melloni's new theory of electrical induction explains them completely. This new theory does not entirely overturn the old, as some have mistakenly believed; the former only essentially modifies the latter in some of its parts.

Tenth Experiment.—This is a reply to the note of M. Gaugain, in which he observes that, notwithstanding the various experiments adduced by M. Volpicelli, it is still strongly maintained that induced electricity of the first kind possesses tension.[7]

Eleventh Experiment.—In this are advanced various observations, some on tension, both electro-statical and electro-dynamical, and others on electrical induction.[8]

Twelfth Experiment.—In this communication it is observed

that continuous electrophoroi furnish, when carefully examined, a clear proof that induced electricity does not possess any tension. In fact, in the case of these machines, as in that of frictional machines, the conducting spikes of the prime conductor possess the two opposite electricities co-existent on the same points; this is easily shown by means of a very small proof-plane.[1]

Thirteenth Experiment.—It is shown, by means of Geissler's tubes submitted to the electrical influence, that induced electricity of the first kind has no tension.[2]

Fourteenth Experiment.—Here it is observed that the proof-plane, whether submitted or not to electrical induction, always receives by contact a charge greater than that which is free on the element which it has touched. Then the *coibent*, always indispensable in the construction of the proof-plane, receives, by infiltration, a certain quantity of electricity, besides that obtained by communication with the metallic part. This infiltration or absorption varies not only with the nature of the *coibent*, but also with its quantity, within certain limits. This communication[3] contains other observations on electrical induction, and it is concluded that on the extremity of the induced body nearest to the inductor, the two opposite electricities coexist, and that consequently induced electricity of the first kind has no tension. It is also concluded that the homonym of the inductor is always found on whatever point of the induced body this may be, and that the homonym indicated is the only one to be dissipated, because it alone is the only one endowed with tension.

Fifteenth Experiment.—In this is explained Nicholson's duplicator, which is satisfactory, since it is based on the want of tension in induced electricity of the first kind.[4]

Sixteenth Experiment.—In this is shown how we may shield from curvilinear induction the electroscope which hangs from the extremity of the induced body nearest to the inductor. From this experiment it is concluded that the divergence of the straws is due principally to curvilinear induction, and that induced electricity of the first kind does not possess tension.[5]

Seventeenth Experiment.—In this is analysed a little known electrostatic phenomenon; and from this analysis it follows that induced electricity of the first kind has no tension.[6]

Eighteenth Experiment.—It is shown mathematically that electric induction does not traverse conducting masses. It is afterwards observed that first the Florentine academicians and then Faraday admitted this truth. It is also observed that if we admit that induced electricity of the first kind possesses no tension, we arrive at the conclusion given below by means of experiment.[7]

CONCLUSION.—Upon an insulated conductor submitted to the electric influence—1. Induced electricity of the first kind does not possess tension. 2. It is found in greater quantity at the extremity of the induced body nearest to the inductor, and diminishes always as it approaches the other extremity. 3. Induced electricity of the second kind, *i.e.*, the homonym of the inductor, is found on every point of the induced body, not excepting the extremity nearest to the inductor; it continually increases in proportion as it approaches nearer to the other extremity, and is always free.

SCIENTIFIC SERIALS

Mind—A Quarterly Review of Psychology and Philosophy. Edited by George Croom Robertson, M.A., Professor of Philosophy of Mind and Logic, in University College, London. Jan. 1876.—*Revue Philosophique de la France et de l'Etranger.* Dirigée par Th. Ribot. Première Année. Janvier 1876: Paris.—The growing importance of psychology has been asserted by the simultaneous appearance of a French and an English review, especially devoted to its interest. In scope and character the two publications are identical. One aim of the projectors of *Mind* seems to be to obtain a decision of the question: Is psychology a science? "Nothing less, in fact, is aimed at in the publication of *Mind.*" The first number opens with a lecture on "The Comparative Psychology of Man," read before the Anthropological Institute, by Mr. Herbert Spencer. It is one mass of valuable suggestions, and every reader will follow with interest the divisions and sub-divisions under which Mr. Spencer recommends that the subject should be studied.—Next follows under the title "Physiological Psychology in Germany," a rather lengthy account, by Mr. James Sully, of a work by Prof. Wundt of Leipzig. The other leading articles are in their order:—"Consistency and Real Inference," by Mr. John Venn; in which the comparative merits and defects of the conceptualist and material views of logic are considered. Towards the end of the article Mr. Venn refers to what he calls an irrelevant difficulty which sometimes puzzles the student of Mill. How, asks the student, can Mr. Mill, while professing to be an idealist, lay it down that logic has to do with the facts or things themselves, rather than with our ideas about them? We do not see that the consistency of Mr. Mill would be very conclusively vindicated even were it the fact that he did not allow his idealism to interfere with his logic more than does an idealistic astronomer allow his metaphysics to affect his astronomy. But does not Mr. Mill fall back on his idealism when in his discussion with Mr. Herbert Spencer as to the number of terms in the syllogism, he maintains that the things named in the premises and conclusion of a syllogism are our sensations or expectations of sensations, while Mr. Spencer holds the things spoken of to be so many separate objective entities? In an able and interesting paper, Mr. Henry Sidgwick discusses "The Theory of Evolution in its Application to Practice," and finds that when guidance is needed in ethics or politics the doctrine of evolution will not help us. A distinction between "Philosophy and Science," is next worked out by Mr. Shadworth H. Hodgson, in which he displays all his remarkable delicacy of thought. He finds the peculiar scope of philosophy to be "ultimate subjective analysis of the notions which to science are themselves ultimate." We doubt if Mr. Lewes would admit that this is not included in his conception of philosophy as embodied in the really great work on which he is now engaged. An excellent article on "Philosophy at Oxford," is contributed by the Rector of Lincoln College, which it is perhaps not too much to hope may bear some practical fruit. Coming last and occupying the place of the novel in the magazine, is "The Early Life of James Mill," to be continued, by Prof. Bain. In addition to being of intense interest to all who care for mental science, it has been eagerly read and discussed by many who have read nothing else in *Mind.* Short Critical Notices and Reports, and neat little Notes by the editor and others, complete the volume. We sincerely hope Prof. Robertson will be able to keep the *Review* up to the standard of this first number. To make it a commercial success will not be an easy task, for though philosophy has of late been a marketable commodity, that has been when distributed among many periodicals.

Of the *Revue Philosophique* we can say only a very few words. The first number opens with a most interesting and suggestive account, by M. Taine, of observations he made on the acquisition of language by a female child. His speculations about words entirely invented by the child and carrying with them natural meanings, as also his reasonings from the childhood of the individual to that of the race, are ingenious and plausible. He concludes with some excellent remarks on Max Müller's view that in *rational* language we find the distinctive characteristic of man. According to M. Taine the use of words, sounds carrying with them a vague general connotation, is, like the use of ornaments and the use of tools, in common with numerous other indications, an evidence that the stage human has been reached. The psychological condition of this superiority, he continues, will be found in a greater aptitude for general ideas, and its physiological condition in a larger and finer development of brain. In the second article the doctrine of final causes is ably discussed by M. P. Janet, from various points of view. He concludes, however, by maintaining a form of the doctrine, which, as far as we can see, without being able to serve any practical end, supposes a theory that lies wholly outside the boundaries of science. Mr. Herbert Spencer's lecture on "The Comparative Psychology of Man," of which we have already spoken, comes next. The remainder of the number is taken up with reviews of books.

THE *Journal of the Chemical Society* for February contains the following papers:—On the presence of liquid carbon dioxide in mineral cavities, by W. N. Hartley. The author's researches have been chiefly confined to quartz, evidence of the nature of the enclosed liquid being furnished by the specific gravity of the liquid as compared with water (which was also contained in the cavities), and by observing the critical temperature. The author is of opinion that the fluid-cavities of sapphires and rubies also contain carbon dioxide.—On certain bismuth compounds, by

1 "Comptes Rendus," t. 67, p. 843 (Oct. 26, 1868).
2 Ibid., t. 69, p. 730 (Sept. 27, 1869).
3 Ibid., t. 74, p. 860 (March 25, 1872).
4 Ibid., t. 75, p. 257 (July 29, 1872).
5 Ibid., t. 76, p. 169 (Jan. 20, 1873).
6 Ibid., t. 76, p. 1296 (May 26, 1873).
7 Ibid., t. 78, p. 901 (March 30, 1874).

M. M. Pattison Muir. The author has examined the trichloride, tribromide, and the so-called bismuthic acid.—On bismuthiferous tesseral pyrites, by W. Ramsay. The formula of this mineral appears to be (Ni, Co, Fe)(As, Bi)$_3$.—On the occurrence of native calcium chloride at Guy's Cliffe, Warwickshire, by John Spiller.—The decomposition of alcohol and its homologues by the joint action of aluminium and its halogen compounds, by Dr. J. H. Gladstone and Alfred Tribe. Aluminium and its iodide have no action upon methyl alcohol. Ethyl alcohol is energetically decomposed by a mixture of these substances, hydrogen gas being evolved in large quantities and a pasty residue being left, which the authors consider to be aluminic iodo-ethylate. Heated to 275° C. this residue fuses and undergoes decomposition thus :—

$$Al_2 \left\{ \begin{matrix} (C_2H_5O)_3 \\ I_3 \end{matrix} \right. = Al_2O_3 + 3 \left\{ \begin{matrix} C_2H_5 \\ I \end{matrix} \right.$$

The authors have likewise obtained evidence of the existence of aluminic ethylate. Amylic alcohol is decomposed also by these substances. A mixture of the chloride with the metal has no action upon alcohol; the bromide has a decided action.—Ethyl-phenyl-acetylene, by T. M. Morgan. This substance has been obtained by the action of ethyl iodide upon the sodium compound of phenyl-acetylene the two substances being mixed with ether and heated in sealed tubes.—Narcotine, cotarnine, and hydrocotarnine, by G. H. Beckett and Dr. C. R. A. Wright. The authors have studied the action of water upon narcotine hydrochloride, the action of ethyl iodide on hydrocotarnine, narcotine, and cotarnine, and the action of acetic anhydride on all three of these bodies. Dr. Wright adds an appendix on the structural formulæ of narcotine and its derivatives.—Note on incense resin, by Dr. J. Stenhouse and C. E. Groves. This resin is the produce of *Icica heptaphylla*, Aubl., a native of British Guiana. The essential oil contains a hydrocarbon of the empirical formula C_5H_8, which the authors propose to call conimene. To the crystalline resin the authors assign the formula $C_{46}H_{76}O$, and propose the name *icacin*.—On certain sources of error in the ultimate analysis of organic substances containing nitrogen, by G. S. Johnson. These errors are: first, increase of weight by the absorption of oxygen by *nitrite* contained in the solution in the potash bulb owing to the passage of unreduced nitrous anhydride over the ignited copper. Secondly, the presence of occluded hydrogen in the metallic copper reduced in this gas, which is given off on the application of heat and reduces the surface film of oxide, producing water which adds to the weight of the chloride of calcium tube.

SOCIETIES AND ACADEMIES

London

Royal Society, March 16.—Preliminary Reports to Prof. Wyville Thomson, F.R.S., Director of the Civilian Scientific Staff. I. On the true Corals dredged by H.M.S. *Challenger* in deep water between the dates Dec. 30, 1870, and Aug. 31, 1875, by H. N. Moseley, Naturalist to the Expedition.

The author gives a list of the corals dredged in a depth of 50 fathoms and upwards, with notes on each. The whole is necessarily preliminary, on account of the impossibility of sufficient comparisons being made, and references obtained. The results embody great additions to our knowledge concerning the bathymetrical range of corals. Only one coral has been obtained from a greater depth than 1,600 fathoms; it is *Fungia symmetrica*. Only three other corals have been obtained at as great a depth as 1,500 fathoms. Only about twenty-seven genera of corals have as yet been proved to exist in a depth of 250 fathoms and upwards; of these a list is given, to which is added those obtained by the U.S. Coast Survey and the *Porcupine*, making forty-two genera in all. Of these twenty occur in the fossil state. No coral in any way allied to the Rugosa has been dredged by the *Challenger*.

II. On work done on board the *Challenger*, by Mr. John Murray, Naturalist to the Expedition. This Report includes the preliminary notice on oceanic deposits, describing specimens of the sea-bottoms obtained in the soundings, dredgings, and trawlings, over 300 in number, during the years 1873–1875, between England and Valparaiso. The deposits may be classed as follows:—

1. *Shore Deposits*—

(*a*) Blue and green muds.—Met with near the shores of most of the great continents and islands.

(*b*) Grey muds and sands.—Met with chiefly near oceanic islands of volcanic origin.

(*c*) Red mud.—Met with on the eastern coast of South America.

(*d*) Coral mud.—Met with near coral reefs.

2. *Globigerina Ooze*.—An abundant oceanic deposit not met with south of latitude 50° S.

3. *Radiolarian Ooze*.—An oceanic deposit met with only in the Western and Middle Pacific.

4. *Diatomaceous Ooze*.—An oceanic deposit met with only south of 50° S. latitude.

5. *Red and Grey Clays*.—The most abundant oceanic deposit.

The deepest sounding (4,475 fathoms) was a Radiolarian ooze.

In the early part of the cruise many attempts were made by all of the naturalists to detect the presence of free protoplasm in or on the bottoms from the soundings and dredgings, but with no definite result. It was undoubted, however, that some specimens of the bottom preserved in spirit assumed a very mobile or jelly-like aspect, and also that flocculent matter was often present.

At this point Mr. Buchanan determined that the flocculent matter was simply the amorphous sulphate of lime precipitated by spirit from the sea-water associated with the ooze. Subsequently a number of experiments were made, in conjunction with Mr. Buchanan, upon the behaviour of this amorphous precipitate when precipitated with different quantities of spirit, and when treated with colouring solutions. The precipitate was also examined alone and mixed up with some of the ooze. The ooze was examined at the same time, and in the same manner, but without having been treated with spirit. The results were shortly these:—

"When sea-water is treated with twice its volume of spirit or less, nearly the whole of the amorphous precipitate assumes the crystalline form in a short time.

"When treated with a great excess of spirit the precipitate remains amorphous, and assumes a gelatinous aspect.

"This gelatinous-like sulphate of lime colours with the carmine and iodine solutions, and when mixed with the ooze has, under the microscope, the appearances so minutely described by Haeckel.

"The ooze washed with distilled water, or taken just as it comes up, and treated in the same manner with colouring solution, does not show these appearances."

When it is remembered that the original describers worked with spirit-preserved specimens of the bottom, the inference seems fair that *Bathybius* and the amorphous sulphate of lime are identical, and that in placing it amongst living things the describers have committed an error.

A preliminary report on vertebrates is then given, containing a list of all the fishes taken in the trawl or dredge. New forms necessitate modifications in the definitions of some families, but it has not been found necessary to establish any new families. The deep-sea and oceanic forms belong to the families—*Stenoptychidæ*, *Macruridæ*, *Ophidiidæ*, *Scopelidæ*, *Stomiatidæ Pediculati*, *Halosauridæ*, *Notacanthi*, *Murænidæ*, and *Trachinidæ*.

Of the Petrels and Penguins very extensive collections have been made, as skins and as spirit specimens. Two or three skeletons of very large specimens of the Sea-elephant have been preserved.

III. On observations made during the earlier part of the voyage, by the late Dr. R. von Willemoes-Suhm, naturalist to the Expedition. This report is on the Atlantic fauna only. Among the most interesting results obtained may be mentioned briefly the facts that shrimps in great depths are liable to be attacked by considerably large Gordiaceous worms; that a curious intermediate form between Priapulids and Sipunculids has been discovered; that relations of the famous Jurassic Eryonidæ are still living in the great depths, where they are (in the Pacific at least) by no means rare.

March 23.—"On the Force caused by the Communication of Heat between a Surface and a Gas; and on a New Photometer," by Prof. Osborne Reynolds, communicated by B. Stewart, F.R.S., Professor of Natural Philosophy in Owens College, Manchester.

This paper contains an account of an experimental investigation undertaken with a view to support, by absolute measurements, the theoretical arguments by which the author endeavoured to prove the existence of reactionary forces or "heat-

reactions, whenever heat is communicated from a surface to a gas, and *vice versâ*, and the connection between these forces and the motion caused by heat and light falling on bodies *in vacuo*.

Having obtained one of the beautiful little "Light-Mills" constructed by Dr. Geissler, of Bonn, the author was in a position to make quantitative measurements of the effects produced, and of the force producing them.

In the first place, with regard to the sufficiency of the residual air to cause the motion. It was found that this air is, with the exception of the friction of the pivot, which is found to be so small as to be inappreciable, the sole cause of the resistance which the mill experiences, of the limit which is imposed on its speed for such intensity of light, and of the rapidity with which it comes to rest when the light is removed. The law of resistance, as determined by careful measurements, is found to agree perfectly with the resistance which highly rarefied air would offer to its motion; and this law is distinctly special in its character, being proportional to the velocity at low speeds, and gradually tending towards the square of the velocity as the speed increases.

Having established the fact that there is sufficient air in the mill (and Mr. Crookes's behaves in the same manner as this mill) to balance, by its resistance, the force which moves the mill, it is argued that all question as to the sufficiency of the air to cause the forces is removed. What the air can prevent it can cause.

As regards the possibility of the motion being in any way the direct result of radiation. This supposition the author had previously shown to be directly contradicted by the fundamental law of motion that action and reaction are equal. A cold body runs away from a hot body, while, if free to move, the hot body will run after the cold body, showing that the force does not act from body to body, but that each body propels itself through the surrounding medium in a direction opposite to its hottest side, the effect of one body on the other being due solely to the disturbance which it causes in the equilibrium of temperature.

Besides proving that the force acts between the vanes of the mill and the medium immediately surrounding them Dr. Schuster's experiments furnish a quantitative measure of the actual force. From this measure it is shown on theoretical grounds that the difference of temperature on the two sides of the vanes necessary to cause heat-reactions of this magnitude could not be less than $1^{\circ}\cdot7$, while the probability is that it is considerably more.

In order to apply this test and see how far the actual difference of temperature in Dr. Schuster's experiments correspond with that deduced from the theory, a new photometer was devised by the author with an immediate view of measuring the difference of temperature caused by light on a black and a white surface.

Of two thin glass globes, $2\frac{1}{4}$ inches in diameter, connected by a syphon tube $\frac{1}{8}$ inch internal diameter, one was blackened with lamp-black on the inside over one hemisphere and the other was whitened with chalk in a similar manner, the two clean faces of the globes being turned in the same direction. Oil was put in the tube and the globes were otherwise sealed up. Any light which enters through the clean faces is received on the black and white surfaces, and the air in the globes expands in accordance with the difference of temperature which they attain, moving the oil in the tube. A motion of $\frac{1}{2}$ an inch on the part of the oil shows a difference of $2^{\circ}\cdot2$, in the temperature of the air within the globes.

The instrument so constructed is exceedingly delicate, and will show a difference in the intensity of light sufficient to make one revolution per minute difference in the speed of the mill.

Measured with this instrument, the difference of temperature caused by the light necessary to give the mill 240 revolutions per minute does not exceed 24°, and is probably less than this, which shows that the theoretical difference of heat necessary to cause the heat-reactions is well within the difference as actually measured, leaving an ample margin for error in the methods of approximation used in the calculation.

In concluding the paper the author claims to have set at rest the only point respecting the explanation of the motion caused by heat, which remained doubtful after he had discovered that, according to the kinetic theory, the communication of heat to a gas must cause a force reactionary on the surface, viz., whether this reaction was adequate in amount to cause the results seen to take place.

He adds a suggestion as to a new form of light-mill to have vanes inclined like the sails of a windmill, and not having one side white and the other black, like the light-mills at present constructed. Arguing that the forces act perpendicularly to the surface, and in a direction independent of that from which the light comes; so that such a mill would turn like a windmill with the full and not merely the differential effect of the light. Such a mill, he concludes, would furnish another test as to whether or not the force is directly referable to radiation.

Geological Society, March 22.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—Frank Campion, Henry J. Gardiner, Henry Percy Holt, Lord Rosehill, Harold Underhill, Frederick Thomas Whitehead, and Thomas Wrightson were elected Fellows of the Society.—On the Triassic strata which are exposed in the cliff sections near Sidmouth, and a note on the occurrence of an Ossiferous zone containing bones of a *Labyrinthodon*, by H. J. Johnston Lavis. The author described the base of the cliffs east of Sidmouth as composed of the marl which is the uppermost subdivision of the Trias in South Devon, capped in Littlecomb Hill and Dunscomb Hill by greensand and chalk, and in Salcombe Hill by greensand alone. In the valley of the Sid it is largely exposed at the surface. Close to the mouth of the Sid the upper sandstone crops out beneath the marl, forming a cliff overhanging the river. To the west of Sidmouth there is a low projecting cliff, the Chit rock, formed also of the upper sandstone, and at the western end of this is a fault which has given the Chit rock an upthrow of at least 40 and perhaps of 80 feet, since it has no marl capping it, and in its lithological character it resembles the middle part of the Upper Sandstone. To this point the dip is to the east; but westward of the fault the dip is at first to the west for about half a mile, when the sandstone reappears with an easterly dip, having formed a synclinal curve. It is overlain by marl and greensand in Peake and High Peake Hills, which are capped with chalk gravels. West of High Peake Hill the sandstone forms the whole cliff. The author described the general characters presented by the Triassic beds in the section under notice, and mentioned the occurrence at about 10 feet from the top of the sandstone of a peculiar series of beds, composed of coarse sandstone, containing scattered nodules of marl from the size of a pea to that of a hen's egg, together with numerous fragments of bone, some of which, belonging to a species of *Labyrinthodon*, would be described by Prof. Seeley. The author mentioned that he had received from the Rev. S. H. Cooke some fragments of bone obtained by him twenty years ago from this same "Ossiferous zone." Mr. Whitaker's specimen of *Hyperodapedon* was also obtained from the upper sandstone.—On the posterior portion of a lower jaw of *Labyrinthodon* (*L. lavisi*) from the Trias of Sidmouth, by Mr. Harry Govier Seeley, F.L.S., Professor of Physical Geography in Bedford College, London. After referring to the doubtful position of the Labyrinthodontia in the system, and expressing his doubts as to the occurrence of the genus *Mastodonsaurus* in Britain, the author proceeded to describe in detail the posterior part of the right ramus of the lower jaw of a Labyrinthodont, obtained by Mr. Lavis from the ossiferous zone of the Trias near Sidmouth, the position of which was described by that gentleman in the preceding paper. The specimen, which is 13 inches long, and perfectly free from matrix, shows that the lower jaw in Labyrinthodonts not only contains articular, angular, and dentary elements, as hitherto supposed, but also separate splenial and surangular elements, and probably a distinct coronoid bone. These bones were described in detail, and the author remarked that although they are somewhat reptilian in aspect and arrangement, they are not very suggestive as to the affinities of *Labyrinthodon*. They surround a central hollow space, which no doubt received the primitive cartilage round which the bones were ossified; and the persistence of this character would seem to be a link rather with the lower than with the higher vertebrata. The jaw differs from the Batrachian mandible in possessing well-developed angular and surangular elements, and some reptiles, such as crocodiles and the marine Chelonia, present analogies in the perforations, the structure of the jaw, and the sculpture of the bones. In size the specimen is almost identical with that figured by Mr. Miall as belonging to *Labyrinthodon pachygnathus*, but the depths and outlines of the postarticular part of the jaw, and differences in the sculpture of the lateral subarticular ornament, furnish distinctive characters which lead the author to describe the present species as representing a new species, which he names, in honour of its discoverer, *Labyrinthodon Lavisi*. The author briefly noticed several other bones and fragments obtained by Mr. Lavis in the same locality, some of which probably belonged to the same skeleton.—On the discovery of *Melonites* in Britain, by Mr. Walter Keeping, communicated by Prof. T. M'Kenny Hughes. The author described a specimen from the carbo-

niferous limestone of Derbyshire in the museum of the Geological Survey, which displays numerous plates belonging to the test of a large Echinoid, considered by him to be a new species of the genus *Melonites*, hitherto regarded as peculiar to America. The author proposed to call this species *Melonites Etheridgii*, and he described it as possessing a more or less spheroidal test, about seven inches in diameter, composed of very thick plates, arranged in five ambulacral and five interambulacral areas, all the plates being ornamented with minute tubercles for the support of spines. The interambulacral areas were probably about twice as broad as the ambulacral, and composed (at the equator) of about nine ranges of plates, the marginal ones pentagonal, the rest hexagonal, articulating with each other by faces varying from a right angle to one of 30°. The ambulacral areas were broad, each formed of two convex ribs separated by a meridional depression running from mouth to anus, and each rib (half-area) composed of six or seven ranges of irregular plates, each perforated by a pair of simple pores. The tubercles are minute, imperforate, without boss, and of two orders, the larger surrounded by a smooth areola, bounded by an elevated ring. The spines are small, tapering, coarsely sulcate, with a prominent collar round the articular end. A second specimen exists in the British Museum. The species differs strikingly from the North American *Melonites multiporus* in the characters of the ambulacral areas, which have 12–14 ranges of plates, and are divided by a meridional furrow in the new species, and only eight ranges of plates, with a median ridge formed of plates twice as large as the rest in *M. multiporus*.—Note on the phosphates of the Laurentian and Cambrian rocks of Canada, by Principal Dawson, F.R.S. The author described the mode of occurrence of phosphatic deposits in various localities in Canada. Dark phosphatic nodules, containing fragments of *Lingulæ*, abound in the Chazy formation at Allumette Island, Grenville, Hawkesbury, and Lochiel. Similar nodules occur in the Graptolite shales of the Quebec group at Point Levis, and in limestones and conglomerates of the Lower Potsdam at Riviere Ouelle, Kamouraska, and elsewhere on the lower St. Laurence; these deposits also contain small phosphatic tubes resembling *Serpulites*. The Acadian or Menevian group near St. John, New Brunswick, contains layers of calcareous sandstone blackened with phosphatic matter, consisting of shells and fragments of *Lingulæ*. The author described the general character of the phosphatic nodules examined by him at Kamouraska, and gave the results of analyses made of others from various localities, which furnished from 36·38 to 55·65 per cent. of phosphate of lime. A tube from Riviere Ouelle gave 67·53 per cent. The author accepted Dr. Hunt's view of the coprolitic nature of the nodules, and inclined to extend this interpretation to the tubes. The animals producing the coprolites could not be thought to be vegetable feeders; and he remarked that the animals inhabiting the primordial seas employed phosphate of lime in the formation of their hard parts, as had been shown to be the case with *Lingulæ*, *Conularia*, and the Crustaceans. The shells of the genus *Hyolithes* also contain a considerable portion of phosphate of lime. Hence the carnivorous animals of the Cambrian seas would probably produce phosphatic coprolites. With regard to the Laurentian apatite deposits, the author stated that they, to a great extent, form beds interstratified with the other members of the series, chiefly in the upper part of the Lower Laurentian above the *Eozoon* limestones. The mineral often forms compact beds with little foreign matter, sometimes several feet thick, but varying in this respect. Thin layers of apatite sometimes occur in the lines of bedding of the rock. Occasionally disseminated crystals are found throughout thick beds of limestone, and even in beds of magnetite. The veins of apatite are found in irregular fissures; and as they are found principally in the same parts of the seams which contain the beds, the author regarded them as of secondary origin. The Laurentian apatite presents a perfectly crystalline texture, and the containing strata are highly metamorphosed. The author's arguments in favour of its organic origin are derived from the supposed organic origin of the iron-ores of the Laurentian, from the existence of *Eozoon*, from the want of organic structure in the Silurian deposit described by Mr. D. C. Davies, and the presence of associated graphite in both cases, from the character of the Acadian linguliferous sandstone, which might by metamorphism furnish a pyroxenite rock with masses of apatite, like those of the Laurentian series, and from the prevalence of animals with phosphatic crusts in the Primordial age, and the probability that this occurred also in the earlier Laurentian. The position of the phosphatic deposits above the horizon of *Eozoon* is also adduced by the author as adding probability to the existence of organic agencies at the time of their formation.

Paris

Academy of Sciences, April 3.—Vice-Admiral Paris in the chair.—The following papers were read:—On the displacement of lines in the spectra of stars, produced by their motion in space, letter from P. Secchi. The author tabulates a number of the observations made by Huggins, Vogel, and himself, and those at Greenwich Observatory, and shows there is considerable contradiction in the results. Might there not, he asked, be some cause of systematic error in the manner of observing or in the instruments? Comparing the dark line F of Sirius with the hydrogen line H β from a Geissler tube, he got always the same result—a shortening of the Sirius waves (contrary to Huggins), when the telescope was carried along by the clock-work, and the assistant was at the seeker to keep it on a fixed point, and corresponding to the slit of the spectroscope; but if the clock-work stopped, or the assistant deranged the position of the star, the bright line was displaced and came into coincidence with the star line. Dispensing with clock-work, the line was found to be on one side or the other according as the star was looked at on one side or the other of the axis of the telescope. A change was also had on turning the spectroscope 180° on its axis. P. Secchi merely points out these possible sources of illusion without trying to explain them.—Observations of sun-spots made at the Toulouse Observatory in 1874 and 1875, by M. Tisserand. In 1874, 237 spots were observed; in 1875 there were only 88. Of the 76 spots observed at least three times in 1874, 41 were in the boreal hemisphere, 35 in the austral, with a mean latitude (+ or —) of 10°·5. Of the 29 observed three times in 1875, 17 were in the boreal, 12 in the austral hemisphere; the mean latitude was 11°·7. M. Tisserand tabulates his observations with reference to diurnal rotation.—Testing for vinic alcohol in mixtures, and especially in presence of wood spirit, by MM. Alf. Riche and Ch. Bardy.—On the spermatia of the Ascomycetes, their nature and physiological *rôle*, by M. Max. Cornu. The spermatia were at first considered by M. Tulasne as fecundating corpuscles; and in support of this was their apparent refusal to germinate in the same conditions as three other sorts of spores. M. Cornu says he has obtained a very complete germination of spermatia in certain cases. Sometimes the action of pure water will suffice to bring them to vegetation, more often it is necessary to add nutritive elements. The facts observed refute the old theory of fecundation, and the simplification introduced into the number of reproductive organs gives a grand unity to the polymorphism of Ascomycetes.

CAMPBELL'S "CIRCULAR NOTES"

My Circular Notes. Extracts from Journals, Letters sent home, Geological and other Notes, written while Travelling Westwards round the World, from July 6, 1874, to July 6, 1875. By J. F. Campbell, Author of "Frost and Fire." 2 vols. (London: Macmillan and Co., 1876.)

ALL who are acquainted with the undoubted merits of Mr. Campbell's earlier work—merits to which not even the most serious and glaring defects in style, matter, and arrangement can render us insensible—will hail with pleasure the appearance of this latest production of his ever lively pen and amusing pencil. We cannot but think that in this, his second venture, the author has greatly profited by some of the severe but not unfriendly criticisms which were elicited by the publication of his first work. Mr. Campbell has, in "My Circular Notes," avoided the grave mistake of mingling together in wild confusion humorously-written notes of travel and sober arguments on difficult scientific questions; and he has exercised, as we think, a very wise discretion in relegating to an appendix the discussion of that important geological problem, the hope of solving which seems to have been his main incitement to undertaking this journey round the world. In perusing this scientific portion of his book, with which of course the readers of NATURE are principally concerned, we are happy to find far fewer examples of that looseness and inaccuracy of language and to miss that dogmatic tone and redundancy of illustration which were the conspicuous blemishes of the author's earlier work. And all these improvements have we think been effected, without any sacrifice of his really graphic and vigorous style of writing upon scientific questions.

Before proceeding to notice the purely scientific portion of "My Circular Notes," we must remark that, even those who care nothing about the geological problems discussed in it, will find very much to interest them in this most lively and amusing record of travels. Those who would realise the curious scenes which may be witnessed in the Western States of North America, where the most volatile elements of old nationalities are uniting to form a new community—those who take interest in that wonderful social experiment which is now being tried in Japan, no less a one than the transplanting, bodily, of the full-grown civilisation of the West among the most conservative races of the East—and those who desire to learn something of the relics of the ancient nations, languages, folk-lore, and creeds of Ceylon—cannot do better than accept the guidance of Mr. Campbell. In him they will find a most vivacious and ever-amusing companion. Yet, on the other hand, his digressions upon such subjects as emigration and the struggle of races, and his treatment of questions like the relationships of languages and the origin of myths, will sufficiently prove that he has thought earnestly upon many social and philological problems, and has aimed at something higher than merely writing a diverting book of travel.

In adopting the method of loosely stringing together extracts from his journal with private letters, and making no attempt to weld them into a consecutive narrative, our author certainly trespasses somewhat upon the indulgence of his readers. This disadvantage is perhaps in some degree compensated for, however, by the freshness and vigour of his descriptions and reflections, appearing as they do, just as at first dashed off in the presence of the strange scenes which inspired them.

The problem on which the author of this work has sought to throw light in making this journey round the world is one of considerable interest to geologists at the present time. In 1840 Agassiz brought forward evidence which soon convinced even the most sceptical that, not only did the glaciers of the Alps at one time extend far beyond their present limits, but that many districts—such as parts of our own islands, for example—which are now entirely devoid of glaciers, must once have been subjected to the powerful erosive action of moving ice. The idea was at once taken up by Buckland, Lyell, and other observers in this country, who showed that the new "Glacial theory" afforded a complete solution of what had hitherto constituted some of the most difficult and perplexing problems of geology.

By some later authors, however, the "Glacial theory," which had soon met with all but universal acceptance, was pushed far beyond those limits which geological observation warranted. It was asserted that, not only did the existing rock-surfaces of the more northern regions of the earth owe some of their later touches to the erosive action of glaciers, but that many even of the grandest valleys and the deepest lakes were entirely scooped out by their agency. Some even went farther than this, and declared that the whole region around either of the poles must at one period have been enveloped by continuous sheets of solid ice ("ice-caps") which extended far into temperate and even tropical latitudes. They maintained, in opposition to the arguments of Lyell, that no changes in the distribution of land and water on the earth's surface could possibly account for the former extension of glaciers, and they invoked the aid of some astronomical cause to account for the alleged phenomena. A few waxed even bolder than this, and insisted that they had found evidence, which warranted them in believing in the regular recurrence, during past geological time, of alternating mild and glacial periods; and several rival astronomical theories were even suggested to account for these supposed rhythmical changes in climate.

Among the foremost of the champions of these extreme views appeared the author of the present volumes. In 1873, he read before the Geological Society a paper in which he attributed the production of the whole valley system of Ireland to the erosive action of a polar ice-sheet. The remarks elicited from several geologists during the discussion of this paper appear to have induced Mr. Campbell, who, during his travels in Scotland, Norway, Iceland, North America, &c., had acquired great skill in recognising the peculiar marks produced by glacial action, to extend the limits of his observations by a journey right round the continent of Europe. What he then saw led him so far to distrust his former conclusions concerning the existence of a universal glacial period and a polar ice-sheet, that he determined to put the question to the severest test possible, by a complete tour of the globe.

Mr. Campbell's mode of arguing this question is as

follows :—At the present time glaciers enter the sea, within the northern hemisphere, down to the latitude of 60°; the sea is frozen and ice-marks are produced on the shore as far south as 40°; and icebergs drop their rocky burdens within 37° degrees of the equator. If there ever prevailed a universal glacial period with a general reduction in the temperature of the whole northern hemisphere, we ought to find traces of glacial action everywhere round the whole globe and extending even to more southern latitudes than 37°. If the ice-cap "ever existed, the marks of it ought to be found on all meridians alike. If ever there was a glacial period in our world, glacial marks ought to be found everywhere, in the same latitudes and at the same levels, in the same state of preservation."

Keeping these premises constantly before his mind, our author found, during his journey of eleven months, quite sufficient evidence to cause him to make a full retraction of his former conclusions on the subject. As far as Chicago he observed everywhere the most striking traces of former glacial action; but in the same latitudes to the westward he found these marks of old glaciers entirely disappearing; and although some signs of glacial action were detected in the Rocky Mountains themselves, yet from this great range onwards to Ceylon they were found to be wholly wanting. Mr. Campbell's previous expedition in eastern Europe had led him to conclusions as to the *local* character of glacial action which were quite in harmony with those obtained in this journey round the globe, and he enunciates the results of his latest observations upon the subject as follows :—"Whether I take marks which can be explained by glacial erosion, such as firths, valleys, lakes, &c., or marks which clearly are not glacial, such as peaks and canons, I find nothing to suggest a general glacial period in America or in Europe;" and he further proceeds to state that he can find no evidence whatever of a recurrence of universal glacial periods such as might result from the action of some astronomical cause.

We have already extended this notice of Mr. Campbell's valuable work to the farthest limits, and must refer to the book itself for the details of the evidence on which his conclusions are founded.

In bringing our remarks to a close, we may add that the author's present views on the influence produced on climate by the changes of level in different districts, resulting in alterations in the direction of ocean currents, &c., appear to be quite in harmony with those so long and firmly maintained by Lyell, in opposition to the cosmical theories of the extreme glacialists. His observations on Western North America are fully confirmed by the more detailed examination of the districts by several of the United States' geologists; and his conclusion that there is no evidence of the former existence of a general "Glacial period" are quite in accordance with those enunciated by Dr. Hector and other observers who have studied the glaciers of the southern hemisphere. Prof. Nordenskjöld has, moreover, shown how completely palæontological evidence of the clearest character disposes of the notion of frequently recurring glacial epochs in past geological times.

We cannot but admire the candour with which Mr. Campbell renounces his previously-expressed opinions; and we may, perhaps, be allowed to express a hope that the facts and arguments which have led him to so greatly modify his views on glacial phenomena, will not be without effect on the minds of others, who, like him, have certainly pushed their conclusions derived from a study of very limited portions of the earth's surface, to generalisations far beyond what those observations can be legitimately made to support. J. W. J.

SCLATER'S "GEOGRAPHICAL ZOOLOGY"

On the Present State of our Knowledge of Geographical Zoology. By P. L. Sclater, M.A., F.R.S. Being the Presidential Address delivered to the Biological Section of the British Association. (London, Printed by Taylor and Francis: 1875.)

WE have received a copy of Mr. Sclater's address as President of the Biological Section of the British Association, at its meeting last year, at Bristol. At the time when it was delivered we had the opportunity of presenting it in full to our readers (*vide* NATURE, vol. xii. p. 374, *et. seq.*). In the independent form now under notice it has added to it a most important appendix, namely, a list of all the works and memoirs referred to in its various sections. When we say that these are more than 420 in number, a fair estimate may be formed of the labour which must have been involved in their collection and classification. Exact references are a most valuable aid to biological research, and prevent the waste of much time during special investigations, and on the subject of the geographical distribution of vertebrated animals, this address of Mr. Sclater's supplies all that can be wanted by anyone either reviewing the subject as a whole, or desiring to obtain the best information on the zoology of any special locality.

The arrangement adopted is regional, the basis being the universally accepted divisions proposed by Mr. Sclater himself. They are thus tabulated :—

I.—Palæarctic Region	*Arctogaea.*
II.—Ethiopian Region	
II*a*.—Lemurian Sub-region	
III.—Indian Region	
IV.—Nearctic Region	
V.—Neotropical Region	*Dendrogaea.*
V*a*.—Antillean Region	
VI.—Australian Region	*Antarctogaea.*
VII.—Pacific Region	*Ornithogaea.*

Each of these regions is divided into sub-regions, which are described separately. Perhaps no better idea can be formed of the extent to which the greater divisions of the globe have been studied, than by a comparison of the number of works and memoirs which have appeared with reference to each, or to parts of each. As might be premised, there has been much written on the animals of the Palæarctic region, considering that it includes Europe, together with North Africa, Siberia, and North China. There are 119 references with regard to it, the most recent including Prof. Lilljeborg's work on the Mammals of Sweden and Norway, Mr. Dresser's "Birds of Europe," Mr. J. Hancock's "Birds of Northumberland and Durham," Dr. Schreiber's "Herpetologia Europaea," the German translation of Dr. N. Severzow's work on the Birds of Turkestan, the late Dr. Stoliczka's "Avifauna of Kashgar in Winter," Lieut.-Colonel Irby's "Ornithology of the Straits of Gibraltar," and the new edition of Bell's "British Quadrupeds."

With respect to the Ethiopian region—the field-work of Sir Andrew Smith, Livingstone, and Du Chaillu—46 are mentioned, and 40 on the Indian region, which has been so much investigated by those who, from other reasons, have had to take up their residence in our Eastern empire. There are 25 works referred to respecting the Nearctic region, and as many as 138 on the Neotropical, which demonstrates how rich a field South America has proved to the students of biology, it being remembered that Mr. Darwin himself obtained the bulk of his practical experience of animal life in that continent. Forty-one works on the Australian and nine on the Pacific region include the remainder of the list. Mr. Sharpe's edition of Layard's "Birds of South Africa," Mr. Hume's "Stray Feathers," Lord Walden's Memoirs on the Birds of Celebes and the Philippines, Mr Scammon's "Marine Mammals of the North-Western Coast of North America," Messrs. Baird, Brewer, and Ridgway's "History of North American Birds," Dr. E. Coues' "Birds of the North-West," Prof. T. R. Jones' "Manual of the Natural History, Geology, and Physics of Greenland," Messrs. Sclater and Salvin's "Nomenclator Avium Neotropicalium," Mr. A. W. Scott's "Elementary Treatise on the Mammals of New South Wales," the late Mr. J. Brenchley's "Cruise of the *Curaçoa*," Dr. Buller's "Birds of New Zealand," being the most important works which have appeared during the last two or three years, on the regions other than the Palæarctic, above referred to.

That several works have appeared since Mr. Sclater's address was delivered—including, among the most important, the late Mr. Blyth's "Catalogue of the Mammals and Birds of Burmah," edited by Dr. J. Anderson, Dr. Dobson, Lord Walden, and Mr. Grote, a special notice of which we hope very shortly to give—and that Mr. Wallace's important two volumes on the "Geographical Distribution of Animals" may be expected very soon, shows how much stress is now being laid on the fauna of different regions, and adds further to the importance and value of the encyclopædic address, the contents of which we have brought before the notice of our readers on the present occasion.

OUR BOOK SHELF

An Elementary Treatise on Curve Tracing. By Percival Frost, M.A. (London: Macmillan and Co., 1872.)

On the Transcendental Curve whose Equation is—

$$\sin y \sin my = a \sin x \sin nx + b.$$

By H. A. Newton and A. W. Phillips. (From the *Transactions of the Connecticut Academy*, vol. iii., 1875.)

MR. FROST'S work is an elementary one, inasmuch as no advanced acquaintance with the differential and integral calculus is required; nor do his methods turn upon the higher algebra, nor upon the science of projections. Indeed he is careful to restrict himself for the most part to fairly elementary processes. It is not a complete treatise, as he does not touch upon roulettes or upon curves, given by intrinsic equations. These latter curves have been, as is well known, discussed and fully illustrated in the late Dr. Whewell's two memoirs in the *Cambridge Philosophical Transactions* (vols. viii. and ix.) We miss, too, all account of curves of historical interest. Occasional notices of these have been given by different writers, but we should like a sketch of them drawn up by some competent hand, with an account of their origin and applications.

Reasons have weighed with Mr. Frost in making these omissions, and we do not grumble at his taking his own line in his treatment of the subject as he has given us a full treatise, abundantly illustrated by figures, of curves, ranging from simplicity to considerable complexity of form. The preface is an interesting one (though by the way, the author was rather unwilling to write it), and in it attention is called to the fact, among other reasons, why junior students should devote some little time to curve-tracing, that the subject of graphical calculation is coming more into use, being applied to problems in statics (see Culmann's "Graphische Statik"), engineering, and crystallography.

We cannot here give any detailed sketch of the contents of the work, further than to draw attention to the last chapter, which treats of the inverse problem, viz., given the form of a curve to investigate its equation, or an approximation to it. We do not remember to have seen the attempt made elsewhere. Should the subject be taken up and carried on with success, we may look for the equation to one's name taking the place of the name on an address card.

The majority of the curves discussed and traced in Mr. Frost's book are algebraical ones.

Messrs. Newton and Phillips write that from the form of a transcendental curve it is not easy to state the equation that will represent it. So instead of taking up the inverse problem, they have selected from out of the host of transcendental equations, and exhibit twenty-four pages of plates of the plane curves furnished by assigning different values to the constant quantities a, b, m, and n in the equation given above.

These forms, as might be imagined, are all symmetrical, and much resemble carpet patterns. The tract is an interesting evidence of the patience and skill at draughtsmanship of the authors.

Kurzes Chemisches Handwörterbuch zum Gebrauche für Chemiker, Techniker, Aerzte, Pharmaceuten, Landwirthe, Lehrer, und für Freunde der Naturwissenschaft überhaupt. Bearbeitet von Dr. Otto Dammer. (Berlin: Robert Oppenheim, 1876.)

TO keep pace with the rapid growth of chemical science would be almost a hopeless task, were it not for the literary organisation and classification undertaken from time to time by such writers as the author of Watts's "Dictionary of Chemistry," and Dr. Dammer, the compiler of the present volume. To writers of this class who take upon themselves the laborious drudgery of "stock-taking," workers in the ranks of science owe a debt of gratitude which cannot be too highly estimated.

In coupling together the names of Mr. Watts and Dr. Dammer, it is by no means our intention to imply any similarity between the respective "dictionaries." Dr. Dammer's work is perhaps more truly a dictionary in the proper signification of the term than Mr. Watts's seven volumes, for while the latter contain full, and in many cases, exhaustive information on the various subjects treated of, the whole of the former is comprised in one volume royal octavo, of some eight hundred pages. The justly esteemed "dictionary" of English chemists need fear, therefore, no rival in the present volume, the two works rather bearing to each other the relationship of a chemical encyclopædia to a glossary of chemical terms.

The longest articles in the present volume are those on absorption, equivalents, alum, ammonia, aniline, aromatic bodies, ashes, animal respiration, atmosphere, atom, base, benzoic acid, benzene, succinic acid, beer, blood, soils, bread, chemistry, chromic acid, steam, diffusion, albumin, electricity, petroleum, nutrition of plants and of animals, acetic acid, acetates, colouring matters, fats, flesh, galvanic batteries, gases, tan, glass, coal, hydrocarbons, madder, crystal, copper, illuminating gas, solution, magnetism, metals, metalloids, microscope,

milk, mortar, nickel, photography, analysis (qualitative and quantitative), nitric acid, nitrates, salts, oxygen, gunpowder, sulphur, sulphuric acid, silver, specific gravity, thermometer, porcelain, hyposulphites, water, wine, tartrates, tungstates, sugar, &c. The following subjects are treated of in some detail:—Alcoholometry, aniline dyes, areometer, iron, carbonates, light, mineral waters, common salt, sulphates, heat.

The value of the dictionary as a work of reference is decidedly enhanced by the adoption of thick type for the words heading the articles. In the case of recently discovered compounds we are of opinion that a short bibliographical reference to the paper wherein such compounds are first made known would have greatly increased the value of the articles without materially adding to their length. The author has fallen into an error in treating of thermo- and pyro-electricity under the same heading; the former term is employed by electricians in this country to denote the electricity developed by heat in *conductors*, the latter to denote the electricity produced by heat in *non-conductors*.

Bearing in mind the enormous range of subjects now embraced by the science of chemistry, for a volume of the present size the amount of information conveyed is really very great. With the exception above pointed out, the articles, though necessarily brief, are to be depended on for accuracy, and we can safely recommend Dr. Dammer's dictionary as a useful work of reference.

R. M.

Clouds in the East. Travels and Adventures on the Perso-Turkoman Frontier. By Valentine Baker. With Maps and Illustrations. (London: Chatto and Windus, 1876.)

THE author of this interesting volume had special facilities for visiting the Russian outposts in Asia and the Persian frontier; he had powerful recommendations to the highest Russian and Persian authorities. By various causes, however, he was prevented from taking complete advantage of these, so that the main part of his work describes his journeys in the district to the south of the Caspian, and from Teheran towards the north-east Persian frontier. He reached the Caspian by Trebizond and Tiflis, and gives some interesting particulars as to navigation on the inland sea. He was able to visit the mouth of the much-talked-of Attrek, and found that the Gurgan, to the south of the Attrek, is the real Russian frontier in this region. He was unfortunately prevented from visiting Merv and Herat, which he had intended to do. Mr. Baker's main objects were sport and to ascertain the real nature of the advances made by Russia in Central Asia. Of the former he got a fair amount around Teheran, and his work will be of very considerable importance to those who are interested in the movements of Russia. He took considerable pains to ascertain Persian feeling on the question; Persia cannot understand, or rather misunderstands, England's inaction. Mr. Baker gives many valuable notes as to the nature of the country passed over, its productions, antiquities, and inhabitants. Concerning the Turkomans especially, and their wonderful houses, many details will be found. Altogether the work is an intelligent and interesting narrative of travel in an important region, and a substantial contribution to the Asian question. There are three good maps, but the chromolithographs are very poor specimens of their kind.

LETTERS TO THE EDITOR

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.]

The Use of the Words "Weight" and "Mass"

I WILL supplement Mr. Bottomley's authorities for the meaning of *gravity* by others which will be perhaps considered more relevant. Maupertuis, "Figure de la Terre," Paris, 1738, writes:—"Il faut bien distinguer ici la pesanteur d'un corps d'avec son poids . . . La pesanteur dans un grand corps, n'est pas plus grande que dans un petit. Il n'en est pas ainsi du poids; il dépend non-seulement de la pesanteur, mais encore de la masse des corps . . . il est le produit de la pesanteur par la masse" (p. 155). Subsequently, he lays down the distinction between pesanteur and gravité which Clairaut adopted; but universally the English *gravity* has been used as synonymous with the French *pesanteur*. Airy, "Gravitation," p. 3: "To take the ordinary force of gravity for an instance, we might measure it by the pressure which is produced on the hand . . . or by the number of inches through which the lump of lead would fall in a second of time . . . But there is this difference between the two measures; if we adopted the first . . . we should find a different measure by the use of every different piece of lead; whereas if we adopt the second . . . we shall get the same measure for gravity whatever body we suppose subject to its influence." Here the broad distinction between "weight" and "gravity" is clearly laid down; the one is the "impressed force" on the falling body, the other its "accelerative effect" (Thomson and Tait, "Treatise on Nat. Phil.," 217–219), or the more familiar "moving force" and "accelerating force." In the "Treatise" the former is called the "force of gravity on the mass of a body," 220; but "gravity" alone seems clearly enough defined as acceleration, by the words "According to this formula, therefore, polar gravity will be

$$g = 32{\cdot}088 \times 1{\cdot}005133 = 32{\cdot}2527."$$

Again, § 226: "The augmentation of gravity per degree . . . is, at most . . . The average . . . differs certainly but little from 32·2."

I think it evident that *gravity* has *not* been "lying ready for use, but left almost idle," as Mr. Bottomley supposes.

To the restriction on the use of weight—which I feebly support, but which is certainly not mine—I do not conceive that the "Act of Parliament" offers any bar; as the weights of masses are merely thereby defined in terms of the weight of the standard mass. This restricted sense is clearly recognised in such passages as the following, from Thomson and Tait's "Elements," § 366, "The measurement of force whether in terms of the weight of a stated mass in a stated locality . . ."

As to the compounds "*centivires*," &c., I advisedly adopted the Latin prefixes in their old etymological sense, so as to have wholly Latin names and thereby prevent any confusion with the C. G. S. kinetic measures. The employment in the metric system being quite conventional and contrary to analogy, I feel justified in following older precedents.

J. J. WALKER

"The Recent Origin of Man"

IN NATURE, vol. xiii. p. 245, a writer over the initials "W. B. D." reviews in no very complimentary terms my book entitled "The Recent Origin of Man." I am charged with inconsistency, inaccuracy, incompetency, &c. When charges of this sort are made they ought not to be made lightly, and the writer making them ought to weigh his statements.

My space is necessarily brief, but I beg permission to comment on a few of the assertions made by "W. B. D." in rendering his judgment on the premises.

1. He remarks: "The statement that no traces of a rude and imperfect civilisation have been met with in the East is refuted by the discovery of enormous quantities of flint implements in Egypt and of neolithic axes in Asia Minor and in India. In the river gravels of both these regions paleolithic *hâches* have been found of the same type as those of Amiens and Abbeville."

We all know that palæolithic implements have been found in the river-gravels of India; I refer to this on p. 31 of my book; but I am not aware that palæolithic implements have been found in the river-gravels of Egypt or Asia Minor. As "W. B. D." asserts it, I beg leave to ask for the particulars.

As for the occurrence of flint implements in Egypt, I remark on p. 478: "Flint implements have been found in Egypt but they belong to the Neolithic age, and occur on the surface, or near the surface, or in the tombs." I mention that one implement of palæolithic type had been found. I show that flint arrow heads and flint knives have been frequently found in the Egyptian tombs by the side of the mummies.

That Sir John Lubbock found in the Nile valley a few implements resembling the palæolithic types I am aware; but implements of palæolithic type were found at Cissbury by Col. A.

Lane-Fox. *No flint implements have been found in Egypt in association with an extinct fauna, or in beds corresponding in geological position to the implement-bearing gravels of the Somme valley.*

2. "W. B. D." asserts that in every one of the cases cited by me (I cite one or two hundred) to prove "the ages" simultaneous, "there is no proof that the deposit has not been disturbed."

I select by way of reply five examples: the pile-village at Unter Uhldingen (Switzerland); the skeletons found at Cumarola, in Italy; the trenches at Alise; the pile-village near Lubtow, in Pomerania; and the relic-beds at Hissarlik.

3. Solutré is a crucial case. Referring to this, "W. B. D." dioposes of it by remarking that a Merovingian cemetery was planted here on a palæolithic station, "as he was informed by Dr. Broca at the French Association at Lyons in 1873." "In this case," he proceeds, "which is made the basis of the attack on the high antiquity of palæolithic men, the human skulls are comparatively modern, and the refuse heap of an untold age."

This statement implies both ignorance and a treacherous memory on the part of "W. B. D."

We are all aware that there are Merovingian remains at Solutré. There are also Roman or Gallo-Roman remains. But the argument from Solutré is this: (1) That the bones of the extinct animals found in association with the flint implements have preserved a portion of their gelatine, and that the horns of the reindeer, when cut, yield the odour of fresh horn. (2) That the flint implements found, though unpolished, are of very superior and advanced workmanship, hardly inferior to the beautiful specimens from Denmark. (3) That there are found here the remains of some 40,000 horses, and that the horse was probably domesticated. (4) That there are numerous instruments here of palæolithic date, some of them in carefully closed stone cists or boxes. The remark of "W. B. D." about the Merovingian graves has therefore no application except in connection with (3) and (4); as regards (3), the *horse-deposit*, as it is called (outside of the refuse-heaps), some of which was compacted into a solidified mass—contained the flint implements and the bones of the mammoth, reindeer, &c.; and, in addition, *extended beneath* the most ancient fire-places, or hearths, containing the palæolithic skeletons and the flints and the bones of the reindeer and mammoth. The horse-remains are not, therefore, Merovingian. As regards (4), and the assertion, on the authority of Dr. Broca, that the graves are Merovingian; this whole subject came up at the French Association at Lyons in 1873; the Association *visited* Solutré; and by way of reply to what "W. B. D." says he gathered from Dr. Broca, I quote from the report of the Proceedings of the Association in "Matériaux pour l'Histoire de l'Homme," 7e, 8e, and 9e Livraisons, 1873, pp. 324, 325, 342. When M. Cartailhac observed that "the discussion was of the greatest gravity, and would remain celebrated in the history of anthropological science," and that although there may have been some disturbances of the soil, "one thing remained certain, viz., that in more than ten instances, a human skeleton had been found on a quaternary fire-place, and not one fact exists to be opposed to the admission of their contemporaneity"—when M. Cartailhac had expressed himself to this effect, the report proceeds:—

"M. Broca partage cette opinion et déclare ouverte la discussion sur le deuxième problème: *les chevaux.*"

Subsequently, participating further in the discussion (p. 342), M. Broca stated that he had examined twenty-five skulls from Solutré, and that of this number seventeen belonged to the epoch of the reindeer—"à la véritable époque paléolithique solutréenne."

I leave "W. B. D." to reconcile these declarations of Dr. Broca made in the public meeting with the private declarations made to him. "W. B. D." closes with the remark that "he has not been able to find [in the book] a single shred of proof of the recent origin of man."

I show that the lake-dwellings in France come down to the eighth century of our era; in Pomerania and Sweden to the eleventh century. I show that great changes of level have occurred in different parts of the earth within a comparatively recent period, as at Uddenalla and Södutalje in Sweden, and in the island of Möen.

I show that in America the remains of the mastodon and mammoth occur in the most superficial deposits—the food sometimes preserved in the stomach; I refer to the preservation of the Mammoth in Siberia; I show that the reindeer and Great Irish Elk lived in Europe down to the Middle Ages; that the Cave-bear survived to Neolithic times, &c. I show that the hippopotamus is figured in the Trojan bed at Hissarlik; that the lion was found in Europe three centuries before our era; that the rhinoceros is found in the neolithic caverns of Gibraltar; that the elephant was brought to Shalmaneser II. by the *Muzri* in the eighth century B.C. I might have added *that the elephant lived in Mauritania (near the Straits of Gibraltar) in the time of Herodotus and Pliny.*

I point out that, owing to the continuance of the ice-sheet, palæolithic man never penetrated into Scotland or Denmark; but that the human period there commences with the Neolithic age, which, interpreted, means that *the Glacial epoch in that region lasted down to the date of the older lake-dwellings.*[1]

JAMES C. SOUTHALL

Richmond, Virginia, U.S., March 20

"The Unseen Universe"

IN Art. 213 the distinguished authors of "The Unseen Universe" say: "We have already shown (Art. 164) that development without life, that is dead development, does not tend to produce uniformity of structure in the products which it gives rise to."

In the article referred to they say: "There is one peculiarity of the process of development now described which we beg our readers to note. We have supposed the visible universe, after its production, to have been left to its own laws, that is to say, to certain inorganic agencies, which we call forces, in virtue of which its development took place. At the very first there may have been only one kind of primordial atom; or, to use another expression, perfect simplicity of material.

"As, however, the various atoms approached each other in virtue of the forces with which they were endowed, other and more complicated structures took the place of the perfectly simple primordial stuff. Various molecules were produced at various temperatures, and these ultimately came together to produce globes or worlds, some of them comparatively small, others very large. Thus the progress is from the regular to the irregular." Is not this a *non sequiter?* "And we find a similar progress when we consider the inorganic development of our own world. The action of water rounds pebbles, but it rounds them irregularly; it produces soil, but the soil is irregular in the size of its grains, and variable in constitution. Wherever what may be termed the brute forces of nature are left to themselves, this is always the result; not so, however, where organisms are concerned in the development.

"Two living things in the same family are more like each other than two grains of sand or two particles of soil. The eggs of birds of the same family, the similar feathers of similar birds, the ants from the same ant-hill, have all a very strong likeness to each other." It seems to me that the argument here tends to show that the planetary or world development, and what the authors term living development, are based on the same primordial law. If development without life does not tend to produce uniformity of structure in the products it gives rise to, and development with life does tend to the opposite result it would logically follow that the worlds with which we are acquainted are the result of living development.

No two living things of the same family are more alike than are the planets of our solar system; alike in form, alike in their motions, and alike in the material of which they are made; and if the doctrine of their growth, maturity, and final dissolution, which the nebular hypothesis ascribes to them, be a verity, then alike in these respects to living development on the earth. I have long been of the opinion that the same principle underlies all development from the smallest microscopic insect to the largest world in the universe, and I am gratified to find two such profound philosophers as Professors Stewart and Tait virtually advancing the same theory. It may, however, be said that they do not admit this sequence. They suppose the visible universe, after its production, to have been left to its own laws, to certain inorganic agencies or forces in virtue of which its developments took place, that at first there may have been only one kind of primordial atom from which all present development has arisen. This is mere speculation; but admitting its verity, it does not alter the truths enunciated by them that dead development does not tend to produce similarity of structure, that the results of the brute forces of nature left to themselves are accidental forms, and that where there is uniformity of structure there is living development.

[1] Certainly not 10,000 years ago; in my opinion not 3,500.

In a careful examination, however, of the whole argument of the authors of the "Unseen Universe," it looks to me as though they saw clearly to what their course of reasoning, as far as this particular point is concerned, tended, but were willing to stop short of the true logical result, believing that humanity was not yet prepared to admit that we are only a small part of one stupendous whole, a universe of individual life.

Of the main object and scope of their argument I have nothing to say, only this: if the premises assumed—and they are the assumptions of the modern school of science—are correct, there is nothing unreasonable in the conclusions at which the authors have arrived.

NOTE.—Since writing the above I have seen the authors' preface to the second edition of the "Unseen Universe," in which they say: "To reduce matters to order, we may confidently assert that the only reasonable and defensive alternative to our hypothesis (or, at least, something similar to it) is the stupendous pair of assumptions that visible matter is *eternal*, and that IT IS ALIVE. If anyone can be found to uphold notions like these (from a scientific point of view), we shall be happy to enter the lists with him." If the distinguished authors will confine themselves to this proposition, that "All visible aggregations of matter, such as our earth and its congeners, are living organisations, in other words, ARE ALIVE," I think the affirmative can be successfully maintained.

Whether matter is eternal and each individual particle or atom of matter is alive, is too far in the interior of the unknowable to be discussed with any possibility of successful results, and, too, the idea of an atom being a living organisation is directly opposed to the whole theory of atomicity, and scientifically ludicrous in view of that theory. Prof. Tait on the Earth's Age

IT is well known that Sir W. Thomson has concluded, from different lines of argument, that the age of the earth, as a body cool enough for habitation, cannot be much greater than a hundred million years.

Prof. Tait, in his "Recent Advances in Physical Science," recapitulates these arguments, but with a different conclusion. He states the limit of age to be about *ten* million years.

As the subject is of immense interest, may I ask Prof. Tait to explain this change of conclusion? J. D. EVERETT

A Relapsed Donkey

SOME years ago on one of the Lucknow roads I met a "Dhobi" (washerman) with some donkeys. I send you a picture of one of them, made by a native artist. It shows, I think, the relationship between the zebra and the donkey better than many which I have seen. Mules and horses often show zebra marks on their legs, but I have never before or since seen the marks so well displayed on the trunk and legs as in this donkey. The stripes on the body are blended together at their base, and so are the stripes on the legs blended into *bands*. At the time I endeavoured to find out whether in the days of the kings of Oudh there had been any zebra in Lucknow which might have bred with donkeys, but could find nothing about it. Had there been a zebra which bred with donkeys, I think there would have been more of these striped animals; but this is the only one I have seen since 1858. I think it a case of simple *atavism*. Perhaps you may think it worthy of a record in NATURE. All "Dhobis" donkeys are small, wretched creatures, mostly with crooked legs. E. BONAVIA

Lucknow, Feb. 29

OUR ASTRONOMICAL COLUMN

VARIABLE STARS.—Mr. J. E. Gore, M.R.I.A., of Umballa, Punjab, calls attention to a star of the sixth magnitude entered in Harding's Atlas, between ϵ Leporis and B.A.C. 1553, and which is underlined. Mr. Gore says: "In February of this year, with a 3-inch refractor, I found Harding's 6 m. star a little brighter than the 9 m. star south of it, but less than several 8 m. stars (Harding) *following*. It has a small companion *f* at about 1′ ±. Harding's 9 m. stars seem about 10 m." Reading off from the Atlas the position of the sixth magnitude for 1800 appears to have been about R.A. 73° 32′·5, N.P.D. 111° 25′, whence for 1876·0 we have R.A. 4h. 57m. 25s., N.P.D. 111° 18′. This star does not occur in Argelander's Zones, nor in the Washington Zones in the volumes of observations for 1870 and 1871.

Gilliss has this note to No. 543 of his Catalogue of 1248 stars for 1840 (B.A.C. 3815): "Probably variable at very short intervals. Of the seven observations three estimations make it 6th magnitude, three 5th, and the other 5·6." This star, which was observed by Flamsteed, Bradley, Piazzi, and Taylor, was also observed by Argelander on three nights, viz., 1850, March 15, 1851, April 22 and 28, the magnitudes being noted on these occasions, 5, 7, 6 respectively. It appears not unlikely that if this star is examined at short intervals Gilliss's suspicion of variability will be confirmed. It is situate in Hydra R.A. (1876), 11h. 2m. 45s., N.P.D. 117° 25′.

As perhaps connected with the subject of variable stars, we may refer to a remark by Piazzi, applying to his star XVI. 35. He says: "Fortiter micans, intereadem, sequens tranquilla luce splendescit." No. 35 is called 8 m., and the star following 15″, and south 18″, which did not exhibit the strong scintillation of its neighbour, 6 m. Both stars occur in the Washington Zone, 1847, June 17, magnitudes 7·8 and 6·7. Also to the remark attached by Lalande to the star of 8·9 mag. observed on the middle wire at 20h. 35m. 39·5s., 1796, August 23, "Beaucoup de scintillation" ("Histoire Céleste," p. 242); this star is No. 40102 Cygnus, of the reduced catalogue, R.A. (1876), 20h. 39m. 23s. N.P.D. 58° 45′·2. Several of the variable stars are well known to exhibit striking scintillation at times, and perhaps more especially when on the point of diminution; this has been particularly the case with S Virginis (Hind, 1851), in which reddish-yellow star flashes of a deeper red are occasionally present, producing an impression of unusual scintillation.

The star Lalande 34746 Aquila is of a deep orange colour. Its position is erroneously given in the reduced catalogue from the observation 1796, June 25; the N.P.D. should be 96° 43′ 28″·7. It does not occur in the Zones of Bessel or Santini. Lalande calls it 7m., and it is entered of the same magnitude in the charts of Capocci and Inghirami. In September, 1873, it was 7·8, so that at present a claim to be included in the list of variables is not quite made out; still as so large a proportion of the highly-coloured stars do prove to be variable, L. 34746 may be worth watching. Position for 1876·0. R.A., 18h. 38m. 2s., N.P.D., 96° 39′·5.

Several of the variable stars to which attention has been called in this column during the last twelvemonth, are now in favourable positions for observation.

THE SEARCH FOR COMETS.—No new telescopic comet has been detected since that found by M. Borrelly at Marseilles early in December 1874, an interval of more than sixteen months. Perhaps we may attribute this circumstance partly to the very unfavourable weather which has prevailed generally during the last year, but it is pretty certain that if a systematic search for these bodies, with suitable instruments, could be instituted by aid of amateurs of the southern hemisphere, cometary astronomy would be greatly the gainer. Such work is not adapted to the routine of the public observatories, nor can they afford, in the actual state of what may be termed the standard astronomy of the other hemisphere, to devote time to it; but it is an occupation especially within the province of the amateur. If his instrumental means are not equal to the determination of accurate positions, he may content himself with intimating any discovery to the astronomers in charge of the public establishments who, after receiving indication of the approximate position of any new comet, will no doubt secure observations sufficient for the calculation of the orbit. In this way it is highly probable that the number of known comets of short period may be materially increased, since it is only at certain returns

that conditions favourable to observation in the northern hemisphere occur. The "comet-seeker" properly so called is an instrument much better known on the continent, and probably in America, than in this country. It may be used for much other useful astronomical work, and if the observer is content to be without equatorial mounting, and rely upon star-maps for ascertaining approximate positions, a first-rate instrument of this class need not involve great outlay. It is true, we believe, that the fine comet-seekers of the kind produced by the continental opticians (those of Berlin and Vienna especially) have, like most other things, increased in their cost during the last twenty years or so, but less perfect instruments would doubtless enable an amateur to do excellent work in the above direction.

TO FIND EASTER

A NEW York correspondent sends us the following rule, which he states to be devised by himself, to find the date of Easter Sunday, perpetually:—

To find Easter "for ever."

Divide	By	And call the Quotient	And call the Remainder
The year of our Lord	19	—	a
" "	100	b	c
b...	4	d	e
$b + 8$	25	f	—
$b - f + 1$...	3	g	—
$19a + b - d - g + 15$	30	—	h
c...	4	i	k
$32 + 2e + 2i - h - k$	7	—	l
$a + 11h + 22l$	451	m	—
$h + l - 7m + 114$	31	n	o

n is the number of the month of the year and $o + 1$ is the number of the day of the month on which Easter falls.

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA[1]

VII.

THE *Carnivora*, as existing at the present day, form a natural group, though very sharply divided into two distinct sections, the Pinniped or aquatic, and the Fissiped or terrestrial forms. The former include the Seals, Walrus, and *Otariæ* or Sea-lions. They differ from the terrestrial carnivora chiefly in modifications of their limbs to suit a semi-aquatic life. In their dentition they also present striking distinctions. Though they have the small incisors, large, pointed, recurved canines, and more or less trenchant molars characteristic of the order; the incisors depart from the typical number of three above and three below on each side, so constant in the other division, being always less numerous, and the molars are simple and uniform in character, never having one tooth differentiated as the sectorial, and others as tubercular molars. The walrus offers a most remarkable modification of dental organisation, which, being unaccompanied by any other deviation from the general structure of the group affords an important caution against placing too great reliance in classification upon characters derived from teeth alone. It must, however, be noted that a knowledge of the complete dentition of this animal in its early stages shows a nearer conformation to the general type than appears at first sight in an examination of the adult. The existing species of Pinnipedia show some gradational forms between the most aquatic species, and those (as the *Otariæ*) which more nearly resemble the terrestrial Carnivores, and upon the supposition that the former have been gradually differentiated from the latter, it might be hoped that palæontology would have revealed some further stages in the series of modifications. At present, however, this expectation has been disappointed. In fact, the fossil remains of seals and seal-like animals as yet known are not numerous or of very great interest, although when those of the Antwerp crags, where they occur more abundantly than elsewhere, have been completely described (a work upon which M. Van Beneden is at present engaged) we may look for further information about them. At present we know of fragments of skulls, jaws, and principally isolated teeth assigned to Pinnipeds, from various Miocene and Pliocene deposits in France, South Germany, Italy, and Bessarabia. The genus *Pristiphoca*, was founded by Gervais on a jaw found in the Pliocene marine sands of Montpellier; it belongs to a form apparently allied to *Stenorhynchus* and *Pelagius*. The Miocene species from Aquitaine, known only by isolated teeth, are referred by Delfortrie to the genus *Otaria*. Tusks of animals of great size, and apparently allied to the walrus, have been found in the Antwerp and Suffolk crags, and received the name of *Trichechodon*, and a lower jaw of much interest, as showing a transitional character between the walrus and the more typical seals, also from Antwerp, has been described under the name of *Alachtherium*.

The fissiped carnivora are distinguished from the seals by their limbs being adapted to terrestrial progression, and by their dentition. The latter is best exemplified by that of the dog, which is one of the most average or generalised forms of the order. Its dental formula is $i\ \frac{3}{3}\ c\ \frac{1}{1}\ p\ \frac{4}{4}\ m\ \frac{2}{3} = 42$, thus only wanting the last upper molar to complete the full typical mammalian dentition. The premolar and molar series are much differentiated from each other in characters, and one tooth above and below is distinguished from all the others by its superior size and special attributes, and hence called in descriptive odontology the "sectorial" or "carnassial" tooth. Though the upper and lower "sectorial" have some adaptive similarity, and work against each other like the blades of shears, they are not the homologous teeth, the upper one being the fourth premolar and the lower one the first true molar. The former consists essentially of a more or less compressed blade, consisting of three cusps, and supported on two roots, and an inner lobe supported on a distinct root. The anterior lobe of the blade is very small, the middle one conical, high, and pointed, and the posterior has a compressed, straight, knife-like edge. The lower sectorial has two roots, supporting a crown, consisting, when fully developed of a compressed bilobed blade, a heel, and an inner tubercle. Great modifications in the characters of these teeth occur in the different genera of the sub-order, recent and extinct, but their essential similarity can be traced in all, though sometimes so disguised as to be recognised with difficulty. The teeth in front of sectorials in both jaws are compressed and pointed, those behind them broad and tuberculated.

The existing genus *Canis*, comprising the animals commonly known as dogs, wolves, jackals, and foxes, may be considered as truly cosmopolitan, being distributed on the American continent from Greenland to Patagonia, and throughout the Old World, and even Australia has its wild dog, though this may belong to a feral race, introduced originally by man. True dogs have also been found in a fossil state in Europe and North America, throughout the Pleistocene, Pliocene, and even Miocene periods. Many of these are only known by fragments and

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.) Continued from p. 450.

isolated teeth. In the early Miocene a very interesting form occurs, named *Amphicyon*, characterised by the greater development of the tubercular molars, which are not only larger relatively than in modern dogs, but the one missing in them is present, making the typical number complete. In addition to this generalisation in the dental characters, they possessed five toes on each foot, whereas the modern dogs have lost the hallux. They were large heavy-limbed animals, and have been supposed to present affinities to the bears, which, however, they only do inasmuch as they are more generalised carnivora than are the typical dogs. Remains have been found in various Miocene deposits in France, Germany, Italy, and some assigned to the same genus in North America. It is doubtful if the cynoid or dog-like type of carnivore was distinctly recognisable in the Eocene period, for the *Canis parisiensis* of the Paris gypsums was founded on a single tooth.

From the dogs, which hold a very central position in the order, the other existing members deviate in two different directions, one extending through the weasels and martens to the otters and bears, which make the nearest approach to the seals, and the other through the civets and hyænas to the cats, the most highly specialised and characteristic carnivores. The true bears are especially distinguished by the great development of the tubercular and the suppression of the sectorial portion of the molar series. The peculiar dentition of a bear is, for a carnivorous animal, highly specialised, and, as might be expected, appears to be a comparative recent introduction upon the earth, not extending beyond the Pliocene epoch, though several transitional forms occur, as *Arctotherium bonariensis* of South America, and *Hyænarctos sivalensis* of the Siwalik Mountain, and *H. insignis* of the Pliocene of Montpellier. Otters have been traced back to the Pliocene in France, and an allied form *Potamotherium*, to the Miocene. *Enhydriodon* is a large otter-like animal from the Siwalik Hills, with very broad and tuberculated molars. The evidence as to the ancient history of the *Mustelidæ* is not very satisfactory, as isolated teeth, by which many of the fossil forms are known, are not sufficient indications as to their general characters.

True *Viverridæ* are met with in the European Miocenes, one genus, *Ictitherium*, forming a transition to the Hyænas. The latter first appeared in the Upper Miocenes of Europe in forms intermediate between the extremes of existing species, and continued abundant until the close of the Pleistocene, but are now restricted to Africa and Asia. The species so common in the British caves appears to have been identical with the Spotted Hyæna (*H. crocuta*) of Africa, and the Striped Hyæna (*H. striata*), has been found fossil in France. The genus has not been met with in America.

The *Felidæ* present the most complete adaptive modification of the carnivorous type for a predatory existence. The jaws are short and wide, the incisors very small, the canines powerful, and the molar series shortened, and its sectorial element developed almost to the complete suppression of the tubercular portion. The limbs and claws have undergone corresponding specialisations. The family has now a very wide distribution, and has existed both in Europe and America since the Miocene period. It acquired one most remarkable modification in the animals known as *Machærodus* and *Drepanodon*, in which the upper canine was developed to an extraordinary degree, projecting down from out o the mouth like huge sabre-like tusks. In other respects the animal was constructed much on the ordinary feline type. They were widely distributed both in time and space, being found in North and South America, in Europe (including Britain), and in India, and ranging from Miocene to Pleistocene epochs, when they became quite extinct.

(*To be continued.*)

UNIVERSITY COLLEGE, BRISTOL

THIS college is now being incorporated under the Board of Trade as a company limited by guarantee, under the Companies' Acts, 1862 and 1867. The Board of Governors is the supreme governing body, and comprises all contributors above 5*l.*, and a large number of honorary members, with various qualifications, resident in various parts of the West of England. The Council is the managing body, consisting of sixteen, one-half of whom are elected by the governors (in the first instance by the contributors of money, about 20,000*l.* having been already promised in Bristol alone), and the other half are nominated by the Vice-Chancellors of the Universities of Oxford, Cambridge, and London, by the two contributing Oxford Colleges, by the Lord-President of the Privy Council, by the faculty of the old-established Bristol Medical School, and by the Principal and professors of the College.

The Council comprises the following names :—

Elected by the Contributors.—W. P. Baker, merchant ; F. N. Budd, barrister ; Rev. J. W. Caldicott, Head Master, Grammar School ; Lewis Fry, School Board Chairman, solicitor ; Rev. F. W. Gotch, Principal, Baptist College ; Rev. J. Percival, Head Master, Clifton College ; G. F. Schacht, pharmacist ; W. Smith, merchant.

Prof. B. Jowett, nominated by Vice-Chancellor of Oxford ; Prof. Stuart, nominated by Vice-Chancellor of Cambridge ; W. L. Carpenter, nominated by Vice-Chancellor of London ; Prof. Henry Smith, nominated by Balliol College ; Rev. H. B. George, nominated by New College ; R. W. Coe, nominated by Bristol Medical School.

At their preliminary meeting, held recently, the Council decided to commence operations in October next, and to appoint at first a Professor of Chemistry and a Professor of Modern History and Literature.

A piece of land has already been secured, but, for the first session or more, the lectures will be given in temporary premises. In all except the strictly medical classes of the medical school (which is being affiliated with the New College), the instruction will be open to young people of both sexes. Other courses of occasional lectures will be organised during the session.

In addition to the aid afforded by Balliol and New Colleges, Oxford, the Worshipful Company of Clothworkers in London have spontaneously offered a very handsome subvention to the College, with the view of establishing a department of Textile Industries for the improvement of the technical education of the West of England cloth manufacturing districts, as Stroud, Trowbridge, &c. It is believed that special attention will be given to the chemistry of dyeing and wool scouring, as well as to the mechanical part of the manufacture. The details of the arrangements are under the consideration of the Council and of a committee of cloth manufacturers and others, by whom very great interest is felt in the proposed scheme.

The registered temporary office of the College is Shannon Court, Bristol, and letters sent to the Secretary of University College, Bristol, at that address, will be attended to.

The Council are seeking for a permanent secretary, and offer a salary of 200*l.* per year. They hope to obtain the services of a gentleman who will throw himself with zeal and interest into the establishment of the College.

THE USE OF YELLOW GLASS FOR ZOOLOGICAL COLLECTIONS

AT a recent meeting of the Entomological Society of Belgium, M. Capronnier read a paper giving an account of some experiments which he had made bearing on the question as to how public collections of insects

may best be exhibited so as to satisfy all the purposes for which they are intended. M. Felix Plateau, at a former meeting, proposed to substitute yellow for colourless glass in lighting rooms containing entomological collections. In the discussion which followed it was suggested that experiments should be made by submitting insects to the influence of glasses of various colours. M. Capronnier was entrusted with carrying out these experiments, and the paper referred to contains his report.

Everyone knows that among the Lepidoptera it is the green and carmine colours which are most rapidly destroyed by daylight. M. Capronnier wished to obtain insects of the year's hatching, but could only obtain sufficient quantities of *Euchelia Jacobæa*, L. The inferior wings of this insect are of a deep carmine, uniform in tone, an important point in the experiments.

The principal colours of the solar spectrum are the yellow, the red, the blue. M. Capronnier rejected the red as giving a tint too dark, and added the mixed colours, violet and green. He had thus four tints chosen with the same degree of tone, and of a moderate shade—yellow, violet, green, and blue, besides a colourless glass. He made five small square boxes of ·08 centimetres square and one centimetre in depth; the whole surface was covered with one of the above-mentioned glasses.

Each wing was fixed in the middle of the box and floated in a bath of very bright light, but protected from the rays of the sun. Each of the wings was partly covered by a band of black paper, and their position was so arranged as to leave exposed successively each of the parts during a period of fifteen, thirty, and ninety days. The following are the results:—

Colourless glass.—After fifteen days of exposure the carmine tint was visibly attacked. After thirty days the alteration was more sensible, and after ninety days the work of destruction had rapidly advanced, and the carmine had passed into a yellowish tint.

Blue.—With this tint the same alterations took place as in the case of colourless glass.

Green.—This colour preserved the carmine during the first fifteen days; a change was indicated on the thirtieth day, and on the nintieth the alteration was marked.

Yellow.—During the ninety days the yellow alone left the carmine colour almost intact. M. Capronnier says *almost*, for a slight alteration in the tint could be noticed at the end of the ninety days. This last observation proves that there is no absolute preservative, and that collections must be kept in darkness, under penalty of seeing them seriously changed at the end of a given time.

Nevertheless, it is evident from the above that the yellow is the best preservative against alterations in the colours of insects. M. Capronnier consequently concludes that a yellowish colour should be preferred and combined in every arrangement of an entomological room. Moreover the cloths that cover the show-cases ought to be yellow rather than green, and what is important and indispensable, the window-blinds ought to be absolutely yellow.

RADIOMETERS[1]

DURING the discussion which followed the reading of Prof. Reynolds's and Dr. Schuster's papers at the last meeting of the Royal Society I mentioned an experiment bearing on the observations of Dr. Schuster. I have since tried this in a form; and as the results are very decided and appear calculated to throw light on many disputed points in the theory of these obscure actions, I venture to bring a description of the experiment, and to show the apparatus at work, before the Society.

I made use of a radiometer described in a paper communicated to the Society in January last. I quote the description from paragraph 184. "A large radiometer in a 4-inch bulb was made with ten arms, eight of them being of brass, and the other two being a long watch-spring magnet. The discs were of pith, blackened on one side. The power of the earth on the magnet is too great to allow the arms to be set in rotation unless a candle is brought near, but once started it will continue to revolve with the light some distance off."

This radiometer was floated in a vessel of water and four candles were placed round it, so as to set the arms in rotation. A mark was put on the glass envelope so as to enable a slight movement of rotation to be seen. The envelope turned very slowly a few degrees in one direction, then stopped and turned a few degrees the opposite way; finally it took up a uniform but excessively slow movement in the direction of the arms, but so slow that more than an hour would be occupied in one revolution.

A powerful magnet was now brought near the moving arms. They immediately stopped, and at the same time the glass envelope commenced to revolve in the opposite direction to that in which the arms had been revolving. The movement kept up as long as the candles were burning, and the speed was one revolution in two minutes.

The magnet was removed, the arms obeyed the force of radiation from the candles, and revolved rapidly, whilst the glass envelope quickly came to rest and then rotated very slowly the same way as the arms went.

The candles were blown out; and as soon as the whole instrument had come to rest, a bar-magnet was moved alternately from one side to the other of the radiometer, so as to cause the vanes to rotate as if they had been under the influence of a candle. The glass envelope moved with some rapidity (about one revolution in three minutes) in the direction the arms were moving. On reversing the direction of movement of the arms the glass envelope changed direction also.

These experiments show that the internal friction, either of the steel point on the glass socket, of the vanes against the residual air, or of both these causes combined, is considerable. Moving the vanes round by the exterior magnet carries the whole envelope round in opposition to the friction of the water against the glass.

As there is much discussion at present respecting the cause of these movements, and as some misunderstanding seems to prevail as to my own views on the theory of the repulsion resulting from radiation, I wish to take this opportunity of removing the impression that I hold opinions which are in antagonism to some strongly urged explanations of these actions. I have on five or six occasions specially stated that I wish to keep free from theories. During my four years' work on this subject I have accumulated a large fund of experimental observations, and these often enable me to see difficulties which could not be expected to occur to an investigator who has had but a limited experience with the working of one or two instruments.

COMPRESSED AIR LOCOMOTIVE USED IN THE ST. GOTHARD TUNNEL WORKS[1]

THE boring of a tunnel of any importance presents difficulties of various kinds, among which may be mentioned the clearing away of the rubbish arising from the excavation of the gallery, whenever that reaches any considerable length, and the work is carried on with activity. Such were the conditions under which the boring of the Mont Cenis tunnel was carried on, and M. Fabre, the able contractor, has met with similar difficulties in the boring of the St. Gothard tunnel, now being carried out.

[1] From an article in *La Nature*, by M. C. M. Gariel.

The work was begun from two points, Airolo and Gœschenen, the two extremities of the future tunnel. The advance of the gallery, which is pushed on with activity, produces about 400 cubic metres of rubbish a day at each of the two faces of attack. To carry away this mass of rubbish, which is thrown regularly into trucks running on rails, it is impossible to employ locomotives, as the *cul de sac* nature of the galleries prevents

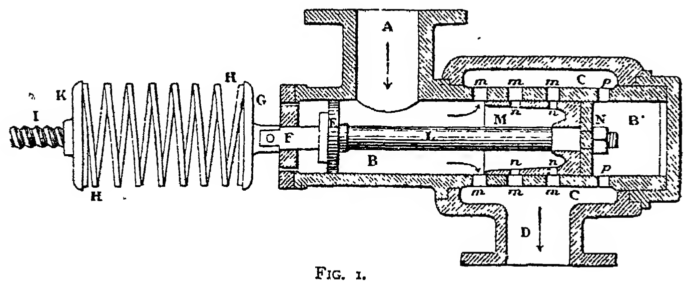

FIG. 1.

effectual ventilation. The high price of horses and the large number required prevent their use. The idea suggested itself of making use for St. Gothard of machines moved by compressed air, which would have many advantages. First, it is well known that compressed air is used to work the perforating machines used in boring the tunnel; then by the employment of compressed air locomotives ventilation of the galleries would be produced, as these machines would allow only pure air to escape; and then these motors would be more powerful than horses, and effect more rapidly the clearing away of the *débris*.

A first attempt was made in which two ordinary locomotives were employed, one at each side of the tunnel; the boilers, in which, of course, there was no water, were filled with condensed air under a pressure of four atmospheres. This air played the part usually done by steam, passed into slide valves, entered the cylinders alternately on each face of the pistons, which it set in motion, and then escaped into the atmosphere.

It is easily seen that if compressed air were to be employed, it would be indispensable to have a very considerable quantity of it; the boiler of a locomotive, sufficient when it is worked by means of steam constantly produced under the action of heat, was too small to contain a quantity of air sufficient for use without being filled. This led to adding to each locomotive a special reservoir for compressed air; each locomotive was accompanied, as a kind of tender, by a long sheet-iron cylinder, 8 metres long and 1½ metres diameter, supported towards its extremities by two trucks, which, on starting, were filled with condensed air, and which communicated by a tube with the distributing apparatus of the cylinders. The locomotive then worked as before, except that compressed air came from the reservoirs instead of from the boiler. The two locomotives, the *Reuss* and the *Tessin*, worked economically for about two years, in spite of the

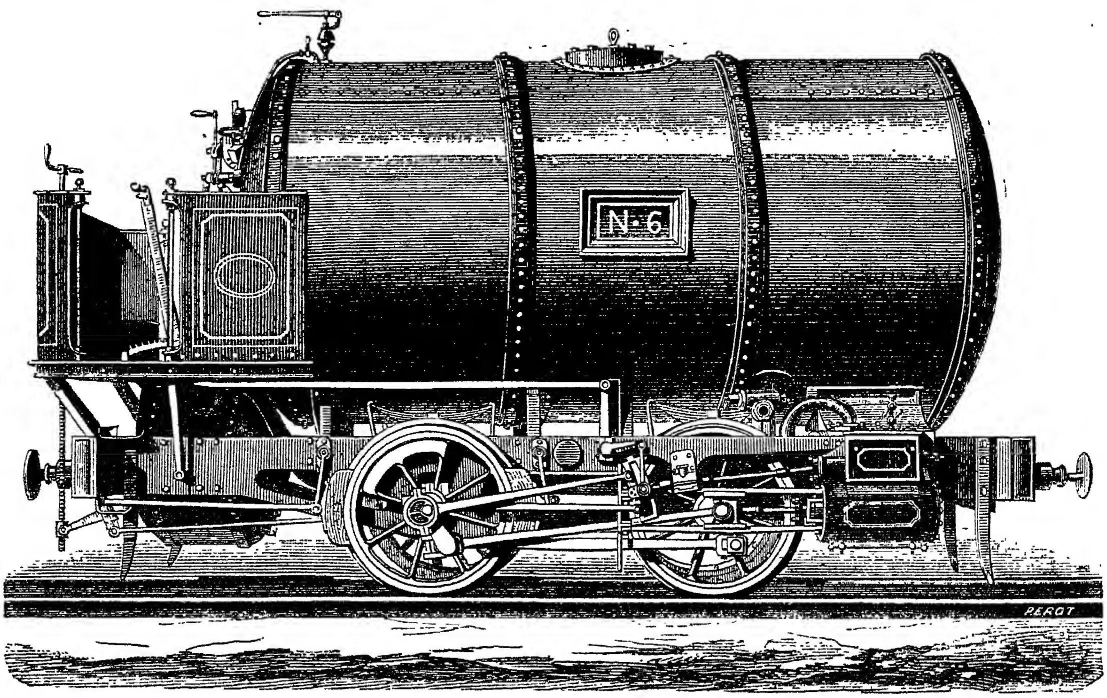

FIG. 2.—Compressed Air Locomotive used at the St. Gothard Tunnel Works.

awkwardness of the long cylinders that accompanied them. We can give some interesting figures resulting from the mean of a certain number of observations. At departure the pressure in the reservoir was about 7 kilogrammes per square centimetre; the locomotive having drawn a train of twelve loaded waggons along a course of about 600 metres, the pressure was found to fall to 4½ kilogrammes; the train then returned empty to the point of departure, and the final pressure was found to be 2½ kilogrammes.

In spite of the relatively advantageous results which were obtained, the employment of compressed air in a steam locomotive presented a certain number of drawbacks. It is expedient that the air should issue from the cylinder under the least possible pressure, in order that refrigeration may be reduced to a minimum; for it is known that the expansion of gas is accompanied by a loss of heat which increases with the pressure. This condition was satisfied by causing the air to act under restraint; that is, by allowing the compressed air coming

from the reservoir to enter during only a part of the course of the piston. But the admission of the air ought to vary if it is desired to obtain the same final effect, since the pressure in the reservoir diminishes continuously; and as the apparatus which regulates the admission was arranged to correspond only to determined fractions, but not to vary in a continuous manner, it followed that there was a greater expenditure of air than was necessary, and consequently a diminution in the length of the course over which the locomotive could run.

On the other hand it is necessary that the air should arrive in the distributing apparatus with the least possible pressure, for it is in this apparatus, in the slide-value, that the greatest losses take place, and these losses increase in proportion to the pressure. No means could, however, be thought of for diminishing the pressure in the reservoirs, which would have reduced considerably the work which the machines were capable of doing, unless by augmenting considerably the volume of the reservoirs, the dimensions of which were already unusually large.

At this stage M. Ribourt, the engineer of the tunnel, devised an arrangement which allows the compressed gas to flow at a fixed pressure whatever may be the pressure in the reservoir. The gas in escaping from the reservoir enters a cylinder B (Fig. 1), over a certain extent of the walls of which are openings *m m*, that communicate with another cylinder C, which surrounds it to the same extent, and which is connected with the slide-valve by which the air is distributed, or, more generally, with the space in which this air is to be utilised. On one side moves a piston E, which shuts the cylinder and hinders the escape of the air. This piston carries externally a shaft F, which supports externally a spiral spring H, the force of which is regulated by means of a screw. Internally it is connected by another shaft L with a second piston N, which bears a cylinder M, movable in the interior of the principal pump, and forming thus a sort of internal sheath. This sheath presents openings *n n*, which may coincide exactly with those already referred to, and in that case the gas passes without difficulty from the reservoir at the point where it is to be employed. But if the sheath is displaced, the openings no longer correspond, there is resistance to the passage, and consequently diminution of the quantity of gas which flows out, and hence lowering of pressure in the exterior cylinder. By making the position of the sheath to vary continuously we may make the pressure of exit constant, notwithstanding the continuous variation at entry. But the apparatus is automatic. In fact the part of the cylinder B comprised between the bottom and the piston N communicates by openings *p* (which are never covered with the escape-tube of the gas), in such a manner that upon its posterior face the piston N receives the pressure of the gas at the moment when it flows, a pressure which it is sought to render constant. The piston E receives on its anterior face the action of the spring which can be regulated at pleasure. As to the other faces of the two pistons, they are subjected to equal actions proceeding from the pressure of the gas at its entry, actions which thus counteract each other; so that the forces which determine the position of the movable system are on the one hand the tension of the spring, a constant and determined force, and on the other hand, the pressure of the flowing gas; and thus equilibrium cannot occur unless the two forces are equal. If the gas should flow in too great quantity, the pressure increases on the posterior face of the piston N, the spring is overcome, and the movable system advances a little towards the left; but then the orifices are partly covered and the flow diminishes. If the pressure then becomes too weak at the exit, the spring in its turn prevails, pushes the sheath towards the right, uncovers the orifices, and consequently a greater quantity of air may enter.

The machines which are now used at the St. Gothard tunnel, genuine compressed air locomotives, are furnished with M. Ribourt's apparatus. They consist of the following parts:—A sheet-iron reservoir to contain the compressed air is mounted on a framework quite like that of steam locomotives, and carrying glasses, cylinders, distributing apparatus, &c. The tube for receiving the air possesses, within reach of the driver, the automatic valve of M. Ribourt. The screw being easily regulated, the air can with certainty be made to issue from the apparatus at a determined pressure. This air then passes into a small reservoir (about one-third metre cube) intended to deaden the shocks, which are always produced when the machine is set agoing or stopped. Lastly, this small reservoir communicates with the cylinders, and the air which reaches them acts in the same manner as steam in ordinary locomotives.

The pressure in the principal reservoir at the point of exit depends on the power of the compressing apparatus; at St. Gothard it may attain 14 kilogrammes per square centimetre, but is ordinarily about 7·35 kilogrammes. The pressure in the small reservoir is arbitrary, depending on the regulation of the screw; at St. Gothard it has a mean of 4·20 kilogrammes. The entire machine weighs about 7 tons.

PHYSICAL SCIENCE IN SCHOOLS

THE passages from Mr. Wilson's essay of 1867 and his letter of 1876 appeared to me in contradiction on the value of science in developing the power of reasoning and of language, since in his letter Mr. Wilson says that science should not be taught to boys till they have attained a certain power of reasoning and language as shown by their attainments in geometry and Latin; and in his Essay he speaks of science as supplying the want of clearness and certitude *better* than arithmetic or geometry, and again, as of all processes of reasoning the exhaustive illustration; and I wished to know whether Mr. Wilson had altered his opinion in the last ten years on this point.

The question at issue is as stated: "Given that boys are going to remain under a system of liberal education till eighteen or nineteen, at what stages is it shown by experience that it is wise to introduce the different sciences?" Certainly my experience has not been so extensive as Mr. Wilson's, but I possess the qualification he demands for forming an opinion, that while (during eight years) I have taught science I have also at various times been occupied with mathematics and with language

The extent to which science should be introduced into the curriculum of a particular school, and the order in which the various subjects should be taken up, cannot, I think, be practically determined without taking into account various points of mere expediency. If, for example, expense were no consideration, I should prefer certain branches of physics, for example, magnetism and electricity, as the subjects for *the first practical* work to be undertaken rather than chemistry. But practically there is this difference, that a class of twenty or thirty boys in practical chemistry can be handled by one master with fair success; whereas the attempt to carry a *class* through any such course of physics as that sketched in Weinhold (translated by Foster) could, I think, only end in failure. Two or three boys to whom one master could give his whole attention might use the book with advantage, but a *class* could not be so handled, except at the additional cost of two or three assistants and considerable time for preparation.

Without, then, asserting that this is the plan theoretically best, we have been led by circumstances at Giggleswick into the following course:—

The school is divided into the upper school, and the lower (or preparatory) school; the upper school consists

of five classes. No science work (at present) is done in the preparatory school, but all boys in the upper school do some. With the lowest class the subjects are physical geography, and in the summer, botany.

The two reasons why science should be taught in schools are (to quote from Mr. Wilson) that it "is the best teacher of accurate, acute, and exhaustive observation of what is," and that "of all processes of reasoning it stands alone as the exhaustive illustration." And the teaching of physical geography and botany I regard as fulfilling the first of these purposes. We enjoy unusual advantages for the study of these two subjects in the nature of the surrounding country. We are upon the millstone grit, but only a few hundred yards from the great Craven Fault, where the mountain limestone is elevated some 800 feet above the grit into the Giggleswick Scar.

At the distance of a few miles we have the limestone and Yoredale rocks resting unconformably upon the vertical Silurian rocks. Traces of glacial action are numerous—the new line from Settle to Carlisle cuts through moraines, where scratched pebbles may be picked up by the dozen. Erratic blocks are scattered thickly over the whole country. At hand we have the Victoria Cave, and the remains it has yielded are preserved in the school museum, and we are within an afternoon's ramble of the summits of Ingleborough and Penyghent, and of Clapham Cave, and numerous others. We are equally well off in the matter of botany; a radius of six miles round the school probably includes a greater variety of plants than any equal area in England.

Supposing a boy to enter the upper school at the age of twelve, he would perhaps remain in the class for a year, and at the age of thirteen would enter upon the *systematic* study of science; and his first subject would be chemistry, which he would attack at once *practically*. Four hours a week are given in this class to the study of chemistry—a practical lesson of two hours and two oral lessons of an hour each. In the class of perhaps twenty-five, all the boys are making the same experiments at the same time, and the work consists mainly in the study of the properties of the salts of particular metals. The boys are led to infer for themselves from their own experiments the solubility or insolubility of the salts of the metals in water, acids, &c., and from that to advance to simple analysis. No text-book is used.

In the oral lessons we advance very slowly; one term suffices probably to get through not more than oxygen, hydrogen, and water, and perhaps to begin air. It seems to me that a boy learns much more by understanding thoroughly the experimental evidence that nine pounds of water contain eight pounds of oxygen, than in learning the "mode of preparation and properties" of the oxides of nitrogen and a dozen other substances. In the next class in which the average age is perhaps fourteen to fifteen, we get through nitrogen, carbon, chlorine, bromine, iodine, fluorine, and perhaps sulphur, practical work being continued at the same rate as before. In the second class we have two hours a week for chemistry, two hours for practical work, and two hours for physics. In physics we take the various branches in succession, and get through the subjects of Balfour Stewart's "Physics" in about two years, which is the time many boys remain in the class, the ages being fifteen to seventeen. In the first class we have eight hours a week. The subjects we are taking at present are:—Inorganic and Organic Chemistry, two hours; Analysis, two hours; Electricity and Magnetism, two hours; Astronomy, two hours.

We shall shortly be able, in consequence of the extension of the buildings, to add some practical work in physics. But this will be only for the highest class.

Will you allow me, in conclusion, to quote some of the conclusions of the British Association Committee on Scientific Education in Schools, which appear to me to be still as important as when they were first written. The Committee included Mr. Farrar, Prof. Huxley, Prof. Tyndall, and Mr. Wilson:—

"There is an important distinction between scientific *information* and scientific training; in other words, between general literary acquaintance with scientific facts, and the knowledge of methods that may be gained by studying the facts at first hand under the guidance of a competent teacher." Both of these are valuable; it is very desirable, for example, that boys should have some general information about the ordinary phenomena of nature, such as the simple facts of astronomy, of geology, of physical geography, and of elementary physiology. On the other hand, the scientific habit of mind, which is the principal benefit resulting from scientific training, and which is of incalculable value, whatever be the pursuits of after-life, can better be attained by a thorough knowledge of the facts and principles of one science than by a general acquaintance with what has been said and written about many.

"The subjects we recommend for scientific *information* should comprehend a general description of the solar system, of the form and physical geography of the earth, and of such natural phenomena as tides, currents, winds, and the causes that influence climate, of the broad facts of geology, of elementary natural history with especial reference to the useful plants and animals. And for scientific *training* we are decidedly of opinion that the subjects which have paramount claims are experimental physics, elementary chemistry, and botany. The science of experimental physics deals with subjects which come within the range of every boy's experience. It embraces the phenomena and laws of light, heat, sound, electricity, and magnetism, the elements of mechanics, and the mechanical properties of liquids and gases. The thorough knowledge of these subjects includes the practical mastery of the apparatus employed in their investigation. The study of experimental physics involves the observation and colligation of facts, and the discovery and application of principles. It is both inductive and deductive. It exercises the attention and the memory, but makes both of them subservient to an intellectual discipline higher than either. The teacher can so present his facts as to make them suggest the principles which underlie them and which once in possession of the principle, the learner may be stimulated to deduce from it results which lie beyond the bounds of his experience. The subsequent verification of his deduction by experiment never fails to excite his interest and awaken his delight.

"Chemistry is remarkable for the comprehensive character of the training which it affords. Not only does it exercise the memory and the reasoning powers, but it also teaches the student to gather by his own experiments and observations the facts upon which to reason.

"Of the value of the elementary teaching in chemistry (at Rugby) there can be only one opinion. It is felt to be a new era in a boy's mental progress when he has realised the laws that regulate chemical combination and sees traces of order among the seeming endless variety. But the number of boys who get real hold of chemistry *from lectures alone* is small, as might be expected from the nature of the subject." W. MARSHALL WATTS

Giggleswick, April 15

We teachers must keep clear in our minds the two sides of the question: the relative educational value of the subject to be taught, and the age or capacity of the pupil. We may roughly classify sciences into those which cultivate the observing, and those which benefit the reasoning powers, though of course all sciences do both to some extent. Of the former, the only one which should be adopted systematically, in my opinion, is botany. Zoology cannot be as practically taught, though the *habits* of all kinds of animals afford infinite opportunity

for training the observing powers of pupils in the country; which should be judiciously directed by the teacher so as to render the observations continuous and systematic as far as they go; they should be always duly recorded, dated, and correctly described. But the encouragement of making collections must be done cautiously, as boys are too prone to be thoughtlessly cruel. Of course information on animals may be given informally. With regard to botany nearly twenty years' experience of teaching boys and girls of all ages and of nearly all classes, has convinced me that it may be commenced as soon as one likes. The plan pursued by my father at Hitcham (of which an account will be found in the *Leisure Hour* for 1862, p. 676) clearly proved the advantage to be derived by village school children, and I can corroborate it by my own attempts in another village; for there was a marked increase in the general intelligence, to say nothing of botany giving the children an amusing and instructive employment in the fields instead of their idling in the street—a fact noticed and strongly approved of by their parents. This subject, whatever may be the objections to others, *can* be taught to almost infants.

With regard to electricity, magnetism, and the elements of chemistry, beyond the last of these, I have no experience, but should fancy that the manipulation required would be unattainable before the ages of eleven or twelve, and the abstract nature of force would scarcely commend itself to the understanding before that age.

Physical geography, however, is another subject which, although affording less scope for the observing powers as botany, is by no means absolutely wanting in this respect. I cannot say that my "young boys [were] more (or less) attentive, active-minded, diligent when they [were] doing arithmetic than when they [were] at a lesson on physical geography." One principle I would insist upon is to appeal to the eye, as well as or rather more than the imagination, of young people. Hence in teaching this science, where no direct observation of the facts is possible (as of glaciers, in Warwickshire), my plan was to procure abundant and good illustrations, while the chief facts connected with their motions and formations would be illustrated by diagrams on the black board. Yet the effects of river and atmospheric action may be actually seen, often to a considerable extent, everywhere; and marine action having been learnt and understood at school, has been eagerly looked for when a visit to the sea-side was forthcoming. Here, however, not only facts should be taught, but their causes, or forces in action which have produced them and the study will then never be dry. Physical geography has its value in realising in the pupil's mind the true nature of sequences between cause and effect, and he thus begins to grasp the fundamental principle of philosophy or "continuity" of action. I have found boys of eight thoroughly able to appreciate the elements of the subject; of course by adapting the facts and reasoning to their capacities.

Physical geography, being simply "modern geology," should invariably precede geology, which above all subjects cultivates inductive reasoning, and I have found boys from about twelve well able to grasp the main facts and reasonings. If they happen to be near any fossiliferous strata or where a variety of rock specimens may be procured, the encouragement to collect as many as possible should be given at any preceding age, for the most fascinating pursuit in science is undoubtedly collecting. (I have to this day crag shells collected at the age of eight, when I was first initiated into geological mysteries.) Collecting, however, is of course only the preliminary stage, and one's scientific lore must not be allowed to rest there.

Before twelve I agree with Mr. Wilson that practical chemistry should not begin for reasons already mentioned. But, however, Mr. Wilson says, "Science should be introduced into a school, beginning at the top and going downwards gradually to a point which will be indicated by experience," surely this is inverting a fundamental principle of education, and we may ask why should science be thus singled out? Why not begin at the top with Latin and arithmetic, and work downwards? Science, however, has its "elements" and its "advanced" stages like everything else. The soundest method seems to me to select the science for each age or capacity of pupils, and for the teacher himself to adapt the branch selected to them. Let him begin with botany—with children of the age of six, if he pleases—and by using the schedule he will find it almost self-adapting to the child's powers, as I have more fully explained elsewhere (see a paper "On the Practical Teaching of Natural Science in Schools," *Educational Times*, March 1, 1876). Physical geography might come next with pupils from eight to twelve, then the experimental sciences or geology from twelve upwards. The observing of the habits of animals might go along with any other science as an out-door instructive amusement, and be limited to no age.

Mr. Wilson talks of the difficulty of a "bored and weary schoolmaster teaching science informally." Passing by the fact that if he be bored and weary, it is largely due to his own want of interest in teaching or in engaging that of his pupils; I would maintain just the opposite opinion, that assuming a teacher to be such, informal teaching in natural history has a wonderful invigorating effect and re-awakens the attention which may have become dull by monotony. Thus I have often found during a lesson in Latin, *e.g.*, Virgil's "Georgics," passages to be constantly occurring when "collateral science" can be invoked. And what is a proof of its value is, that it becomes suggestive to the pupils themselves, so that I have been obliged to check the superabundance of questions lest a Latin lesson should resolve itself into one on natural history.

Beyond such informal teaching as this I would never encourage it as a principle for teachers solely to act upon, with young children, though, of course there need be no restrictions in giving it them; but if science is to be *taught* at all—and all such informal methods are not really teaching—let it be thorough as far as it goes, lest it should lapse into a slipshod informality. It is the charm of the schedule system of botany that it demands close and accurate observation in the dissections, and the writing compels accuracy in the result as well as impresses the facts firmly upon the memory. Mr. Wilson is doubtless right in laying stress upon the necessity of securing abundance of capable teachers, which will probably ever be one of the chief difficulties to contend against. GEORGE HENSLOW

NOTES

M. LEVERRIER has sent to M. Waddington, the French Minister of Public Instruction, a proposal for the immediate construction of the great refractor for the Paris Observatory, which is to be finished in two years and five months. A tender has been sent to M. Leverrier by M. Eichens, the constructor of the great reflector, for that purpose; M. Leverrier proposes the acceptance of M. Eichens' offer.

M. LEVERRIER has been appointed president of the Scientific Committee of the Assemblée des Sociétés Savantes, which is to be held at the Sorbonne next week.

AN Academy of Science has been established at Kansas City, Mo., United States, with appropriate sections for geology, zoology, botany, local history, numismatics, &c. One of the chief objects of the association is to form a museum of specimens which will represent the minerals and fossils, and the fauna and flora of Missouri, Kansas, and the territories.

FROM a communication received by the Scottish Meteorological Society from their observer at Stykkisholm, Iceland, dated

March 11, we learn that the past winter has been particularly mild, the cold having been at no time either persistent or severe. The rainfall has been considerable, and little snow has fallen, and what did fall quickly disappeared. The absence of snow allowed cattle and horses almost always to get good pasturing, and in many places the young sheep were not put under shelter till the end of January, a circumstance almost unprecedented. At the date of writing, the Greenland ice had not made its appearance in the north-west of the island, to which, and to the unusual prevalence of southerly winds, the mildness of the winter in Iceland has been due. The volcano in the Northland has recently shown signs of disturbance by emitting volumes of smoke at intervals, but no ashes or lava has been reported.

SOME time ago an experimental inquiry was undertaken by M. J. J. Müller on a point of considerable importance in reference to our knowledge of the luminiferous ether, viz., whether in light as in the case of sound, the wave-length is dependent on the intensity, or (the same thing) the amplitude of the vibrations. He gave an affirmative answer, and said that the wave-length increases with the intensity. In view of the important issues involved, M. Lippich has recently been led to repeat the experiments, and with arrangements of greater accuracy (about 2,000 times, as he estimates, more accurate than Müller's). From this investigation, of which an account appears in the *Sitzungsberichte* of the Vienna Academy, he concludes, in opposition to Müller, that the wave-length of light, whether in free ether, or in any ponderable media, is *independent* of the intensity of the light vibrations, and so, the duration of vibration being given, a constant depending only on the nature of the medium considered at rest.

THE time elapsing between the action of an external stimulus on some part of the body, and the giving of a signal (previously agreed upon) in reply, has been determined in the case of several senses, by various experiments. A short time ago MM. Vintschgau and Hönigschmied sought to determine this "reaction-time" for sensations of taste on the point of the tongue; and in the subject experimented on, this was found to be, for ordinary salt, 0·1598″, for sugar 0·1639″, for acid 0·1676″, and for quinine 0·2351″. It is interesting to compare the results which the same observers have recently obtained in further experiments as to the reaction-time for sensations of touch on the tongue. This, in the same individual, was found to be 0·1507″ in the case of the tongue being touched with a pencil; a smaller value, therefore, than that of the shortest interval in the former case of taste. In the middle of the tongue the reaction-time, on touching with a pencil, was 0·1527″. A weak electric stimulation of the tongue-point was answered after 0·1813″, whereas with a stronger electric stimulus the answer came in 0·1452″. These numbers represent, in all cases, the averages of all the experiments. It will be seen, then, that the point of the tongue is most sensitive for strong electric stimuli, and the order of sensibility for the remaining stimuli, was (for this individual): Contact, saltness, sweetness, sourness, weak electric stimulation, and bitterness. Other persons on whom similar measurements were made, gave values that were different both relatively and absolutely, and the results for different persons appear to be not comparable together. Various secondary influences play an important part, among which may be cited the thickness of the mucous membrane at the particular part experimented on; this may considerably increase the reaction-time. An estimate of the comparative sensibility of the separate organ of sense can best be had from comparisons in one and the same individual.

MR. W. SAVILLE-KENT, F.L.S., F.G.S., &c., formerly of the British Museum, and more recently of the Brighton, Manchester, and Yarmouth Aquaria, has been appointed Managing Naturalist to the Royal Aquarium, Westminster. Some of the fresh-water tanks are already stocked with fish; the sea-water is being rapidly imported, and it is anticipated that a fine collection of both salt and fresh-water species will be on view in the course of a few weeks.

M. AMÉDÉE GUILLEMIN announces a new edition of his well-known work "Le Ciel," to be published in fifty-five weekly parts. For the new edition the work has been to a great extent recast, in order that account might be taken of all the important recent discoveries and advances in astronomy. The results which have been obtained by means of the spectroscope in relation to the sun and the stars will especially occupy a prominent place in the new edition, which will be larger by one-half than any of its predecessors; the number of plates and woodcuts will also be increased in a like proportion.

M. MARIÉ DAVY has asked the Municipal Council of Paris to grant the necessary funds for the construction of an experimental lightning conductor. The apparatus is to be placed on a pole erected at a distance from buildings, and to have a key, so that continuity may be interrupted for scientific purposes.

M. BERTHELOT, the well-known French chemist, has been appointed Inspector of Public Instruction, in place of M. Balard.

MESSRS. COLLINS AND CO. have sent us a volume containing "Tables, Nautical and Mathematical, for the use of Seamen, Students, Mathematicians, &c., arranged, corrected, and some re-calculated," by Henry Evers, LL.D. The author has mainly followed the best English authorities, and we believe the collection will be found very useful by those for whom it is intended. There are in all twenty-one different tables, and prefixed is an introduction to the Logarithmic Tables, showing how they are used.

IN the last issued part of the *Transactions* of the Manchester Geological Society (Part ii., vol. xiv.) there are papers by Mr. J. Dickenson, on Measuring Air in Mines, and by Mr. Aitken, on Drift Deposits on the *Western* Pennine Slopes of the upper drainage of the rivers Calder and Irwell, with suggestions as to the cause of the partial absence of drifts on the *Eastern* Slopes. Mr. Plant gives some interesting details on a submerged forest near Holmfirth, and Prof. Boyd Dawkins states his belief, from a critical examination of the coal-fields of New South Wales, that there is not much doubt of their being palæozoic.

AT the recent annual meeting of the Asiatic Society of Bengal, Mr. Blochmann read extracts from an account of the Meywa, Bheels, by Dr. T. H. Hendley, Residency Surgeon, Jeypore, Rajpootana, who gives description of those members of the Bheel race who reside in the Hill Tracts of Meywar (Oodeypore), where they have perhaps best preserved their individuality. In the chapter on the religion of the Bheels, Dr. Hendley notices the cairns or sthans, which are erected on the summits of high hills, and the curious reverence of the people for the horse, which, as Sir J. Malcolm says, the Bheels worship, and do not mount. Then follows a description of the customs observed at births, marriages, and deaths, of the government and the agriculture of the tribe, and statistical tables containing race measurements. The Bheel skull is slightly dolichocephalic, and differs very much from the long thin-walled cranium of the pure Hindoo. Mr. Blochmann also read extracts from a paper by Mr. J. A. Smith on the popular songs of the Humeerpore District, N. W. P. This paper contains specimens of songs sung in Bundelkhund in honour of Hurdaul, a son of the notorious Bir Singh Deo Bundila, Rajah of Urcha, who was poisoned by his brother Jhajhar Sing. His ghost is worshipped in every village, and chiefly at weddings in Baisakh. Hurdaul is also propitiated with songs when storms appear.

MR. GILES, with the camels belonging to Mr. Elder, was to leave Champion Bay, West Australia, early last month. He was to examine the tributaries of the Murchison and other rivers on the North Coast, and then push across to South Australia, hoping to reach Adelaide in December.

MR. CAMPBELL DE MORGAN, F.R.S., died on the 11th inst. Mr. de Morgan had contributed some valuable papers to the *Philosophical Transactions* and to the medical journals.

SIR WILLIAM JENNER, BART., will deliver the Harveian Oration on Midsummer Day.

THE Rhind Lectures on Archæology, in connection with the Society of Antiquaries of Scotland, will be given by Dr. Arthur Mitchell, commencing on Tuesday last, and continued on the following Fridays and Tuesdays. There will be six in all, and the subject is, "Do we possess the means of determining scientifically the condition of Primæval Man and his Age on the Earth?"

A BOTANIC GARDEN about twenty acres in extent has been just opened at Southport. In connection with it a museum has been erected containing collections in the various branches of natural history, the entomology of the neighbourhood being well represented in this branch of the museum. Geology has a department assigned to it, and the usual local curiosities, with coins, medals, &c., have a place. The whole of the collections have been well arranged and classified.

IT is proposed to erect an aquarium and winter garden at Clifton, and a committee has been appointed with a view of obtaining a proper site.

MR. JOHN MURRAY announces a new work by Mr. Charles Darwin, F.R.S., on the results of cross and self-fertilisation in the vegetable kingdom.

THE *Journal Officiel* of the French Republic has published an official document estimating the expenses of the International Exhibition of 1878 at 1,200,000*l*.

AN interesting notice has appeared by MM. Becqueral and Edm. Becqueral of the temperatures observed at the Museum, Paris, during 1875, with electric thermometers placed at depths varying from $3\frac{1}{3}$ feet to 118 feet. The mean temperature increases with the depth from $5^{\circ}\cdot3$ at $3\frac{1}{3}$ feet, to $54^{\circ}\cdot4$ at 118 feet. The seasonal range diminishes with the depth, the difference between the two extreme seasons at $3\frac{1}{3}$ feet being $13^{\circ}\cdot5$; at $19\frac{2}{3}$ feet $3^{\circ}\cdot0$; at 36 feet $0^{\circ}\cdot5$; at 101 feet only $0^{\circ}\cdot07$, and at 118 feet the temperature is constant through the year. An interesting point is the disturbing influence on the varying annual and seasonal results according to depth, arising from the different geological strata met with, but particularly from two layers at depths of 49 and 79 feet, through which a constant flow of water percolates to the Seine. In these layers the minimum occurs towards the end of winter, and the maximum in summer, being thus assimilated as regards these annual phases of their temperature to the surface layers.

M. CROVA, professor in the Montpellier Academy, has instituted experiments to determine by calculation what is the value of solar radiation at the limits of the atmosphere. The professor found that for a normal plane exposed to the sun's rays it amounts to two calories per minute on each square centimetre, so that almost every hour a cubic centimetre of water could be heated to 100° C. if no heat were lost by evaporation. Pouillet found the number greater by half, and equal to 231,000 calories per year for each square centimetre.

ON April 1, at 5 o'clock in the afternoon, a partial solar halo (46°) was observed at Paris. The arc (12°) was vertical in the orient of the sun, and at the same distance from the horizon, and the colours were as vivid as an ordinary rainbow. The partial halo was accompanied by a parhelion or triangular mass of light. The interior part of the halo was obscure. The phenomenon lasted for three-quarters of an hour. At 5h. 30m. a vertical column of light going upwards to the zenith was observed.

THE French Minister of Public Instruction, M. Waddington, has visited officially the several establishments of public instruction in Paris, as well as the site of the building to be constructed for the use of the Academy of Medicine. It may be interesting to state that the money required for the building, which we referred to in a recent note, was extorted from the Bank of France during the Commune, under threat of pillage and assassination. The government assented to restore it to the city of Paris, to which it belonged, on condition that it should be devoted to works of public usefulness. The Municipal Council accepting the condition granted it for improving and extending the buildings of the Faculty.

M. LARGEAU and his staff have returned from Rhadames to Constantine after a successful journey. A lecture has been delivered at the Salle Herz, in Paris, by M. Foucher de Careil, a senator, and a concert given on behalf of future explorations by M. Largeau and his colleagues.

MANY persons are under the impression that white cats with blue eyes are deaf; it can by no means, however, be deemed to be so commonly the case as to be an evidence of much consequence in building a theory upon. A New Zealand correspondent sends us some curious facts bearing on the point. "At Taranaki, N. Z.," he says, "I saw a white cat with blue eyes which was not at all deaf, and a good many of its kittens were white and had light blue eyes. As many of these had perfect hearing as were afflicted with deafness. This cat had a grown-up kitten perfectly black which had sometimes also white young ones with blue eyes; it showed, as did the old cat, a singular partiality for them. On one occasion it happened that the old white cat and her black daughter had litters at the same time; amongst them there was only one white kitten with blue eyes—the black cat's. The two fought fiercely for possession of the coveted beauty, and the old cat frequently took it away and placed it amongst her own. One morning the unfortunate object of quarrel was found divided by the recommendation of some feline Solomon, and each cat quite contentedly in possession of half. Both of these litters had some light tortoiseshell-coloured kittens among them, of which a moiety appeared to have their hearing imperfect."

"RAILWAY Appliances, a Description of Details of Railway Construction subsequent to the Completion of the Earthworks and Structures, including a Short Notice of Railway Rolling Stock," is the title of a little work by Mr. John Wolfe Barry, published by Longmans and Co. The work, we believe, will be found of value not only to railway officials of all kinds who desire to have an intelligent knowledge of their duties and of the details of the elaborate system whose efficient working depends on them, but also to the general, and especially the stock-holding, public, who have but a vague idea of the multitude of details which are wrapped up in the little word "railway." Mr. Barry treats in successive chapters of Acts of Parliament and other regulations affecting railways, permanent way, points and crossings, signals, the block system, stations, and rolling stock. The book is plentifully illustrated.

THOSE who are familiar with Dr. J. W. Draper's "History of the Intellectual Development of Europe," will be glad to know that Messrs. George Bell and Sons have published an edition, revised by the author, in Bohn's "Philosophical Library" series.

MESSRS. LONGMANS AND CO. have published as an Appendix to the seventh edition of Ganot's Treatise on Physics,—

"Problems and Examples in Physics." We believe this collection will be found useful by the student of other text-books of Physical Science. There are 217 examples with answers.

MR. F. GREEN, writing from Cannes, April 16, states that he had just seen, for the first time this year, a flight of about half-a-dozen swallows. They were passing over his garden coming from the sea, and going to the N. W. The nearest land to the S. E. from Cannes is Corsica, 110 miles away. Last year the first flight of swallows which he observed at Cannes was on April 11, and on the same day he heard the nightingale for the first time of the season. This season he has not yet heard the nightingale.

THE additions to the Zoological Society's Gardens during the past week include an Indian Wild Dog (*Canis primævus*), a Common Paradoxure (*Paradoxurus typus*) from the Deccan, presented by Col. A. C. McMaster; a Small Hill Mynah (*Gracula religiosa*) from India, presented by Mrs. A. E. Smithers; a Yellow-faced Amazon (*Chrysotis xanthops*) from S.E. Brazil, presented by Mrs. Geo. B. Crawley; two Common Boas (*Boa constrictor*) from St. Lucia, presented by Mr. G. W. Des Vœux; four Trout (*Salmo fario*), a Golden Tench (*Tinca vulgaris*) from British Fresh Waters, presented by Mr. D. Banks.

ABNORMAL MULTIPLICATION AND ABORTION OF PARTS IN MEDUSÆ[1]

PROF. L. AGASSIZ describes as of very rare occurrence upon the American coast, a peculiar variety of *Sarsia*, presenting six radial tubes, six oulli, and six tentacles. It therefore becomes the more interesting to state that I met with a precisely similar variety on the east coast of Scotland. Moreover, the occurrence of this variety appears to be as rare in the one locality as in the other; for of all the many thousands of *Sarsia* which fell within my observation last summer, I only met with one specimen of the variety in question.

In nearly all the species of naked and covered-eyed Medusæ which I had the opportunity of examining, there was a remarkable absence of monstrous or mis-shapen forms. In the case of one species, however, such forms were of frequent occurrence. This species was *Aurelia aurita*, and the monstrosities showed themselves both as abnormal multiplications and abortions of parts. In all the cases of asymmetrical multiplication which I observed, the peculiarity was confined to the lithocysts, and always showed itself in the same manner. That is to say, I have several times observed, in otherwise normal specimens of *Aurelia aurita*, the presence of nine instead of eight lithocysts, and in all these cases the supernumerary lithocyst—which was always fully formed and provided with the usual hood—was placed beside and in close contact with one of the normal lithocysts. This latter fact appears to me important when considered in relation to the theory of Pangenesis; for upon this theory it would follow that if a supernumerary lithocyst is to be developed at all, we should expect it to be so in apposition with one of the normal lithocysts rather than in any other position. Our ground for expecting this, of course, is that the theory of Pangenesis supposes similar gemmules to have a mutual affinity for one another; and as lithocyst gemmules would naturally be plentiful in the region of any normal lithocysts during the process of its development, or of its repair if injured, if anything went slightly wrong in either of these processes, facilities would be offered for the adhesions of improper gemmules at the point where the disturbing cause acted, and these improper adhesions having once taken place, and being then followed by normal adhesions of proper gemmules, the result would probably be a duplex organ.

I have said that in all the cases of asymmetrical multiplication of parts which fell under my notice, it was the lithocysts alone that were affected. But besides these cases of asymmetrical multiplication of parts in *Aurelia*, I saw several instances of strictly symmetrical multiplication, and in all these instances every part of the organism was equally—or rather proportionally—affected. That is to say, as in the single instance of multiplication of parts which I observed in *Sarsia*, all the organs of the nectocalyx—eye-specks, tentacles, and nutritive tubes—were similarly affected; so in the several instances of multiplication of parts which I observed in *Aurelia*, all the organs of the umbrella were similarly affected. If anyone will turn to the admirable plates contained in Prof. L. Agassiz's third contribution to the Academy of Arts and Sciences, and representing a normal specimen of the genus *Aurelia*, he will see that the nutritive canals bear a very definite and symmetrical arrangement with reference to one another, and also with reference to the ovaries and lithocysts. In particular, there are sixteen principal radial tubes that proceed in straight lines and without branching from the centre to the circumference of the umbrella. Of the sixteen tubes, one passes directly to each of the eight lithocysts, while the remaining eight tubes alternate with these. Thus the sixteen radial tubes together mark out, as it were, the whole umbrella into sixteen equal segments. Well, in all the examples which fell under my notice of abnormal multiplication of parts in *Aurelia* (other than those of mere duplication of lithocysts), the precise and peculiar symmetry just described was strictly adhered to; in all these examples the undue multiplication extended proportionally to ovaries, nutritive tubes, lithocysts, and tentacles; so that its effect was to increase the *number* while adhering to the *type* of the natural segments above described. It is further remarkable that in all the instances I met with, the degree of abnormal multiplication was the same; for in all the instances the ovaries were six, the principal or unbranched radial tubes twenty-four, and the lithocysts twelve. All the parts, and therefore all the natural segments, were thus in all the observed instances increased by one-third of their normal number. It is curious to note that we have here the same proportional increase as has already been described in the case of *Sarsia*. This, of course, may be a mere accident; but whether or not it is so, I think that, as there is certainly no reason either in the case of *Sarsia* or of *Aurelia* to regard the forms in question as distinct species, it becomes worth while to draw attention to the very definite manner in which the abnormal multiplication of parts seems always to occur in these the only genera of Medusæ in which such multiplication has as yet been observed. It is perhaps worth while to add that in all the cases where I noticed this undue multiplication of parts, both in *Sarsia* and in *Aurelia*, the animals were remarkable for the unusual amount of nervous energy which they displayed. There can be no doubt that this fact is to be attributed to the unusually large supply of nervous matter that was secured to the organism by the multiplication of its marginal bodies.

As regards abortion of parts in *Aurelia aurita*, I cannot say that I have ever observed this to occur in any organs other than the ovaries. In these, however, suppression to a greater or less extent is of pretty frequent occurrence. Most usual is the case where one of the four ovaries is of smaller size than the other three. Often the abnormal diminution extends to two alternate or adjacent ovaries, and occasionally to three. More rare is the case of total suppression of one ovary. Only on about a dozen occasions have I seen total suppression of two ovaries, and in these it was sometimes the adjacent, but more frequently the opposite organs that were missing. Lastly, on one occasion I observed, in an otherwise well-grown specimen, a total absence of three out of the four ovigerous pouches. In no case, it may be added, did I observe that a deficiency or absence of ovigerous pouches entailed any corresponding deficiency or absence of any other organs.

I have said that, so far as my experience extends, neither reduction nor complete suppression of parts appears to occur in any organs of *Aurelia aurita*, other than the ovaries. It therefore becomes necessary to add that one or more of the lithocysts with their hoods are frequently to be seen of smaller size than the others. As these variations, however, are usually attended with a deficiency of the general tissue of the umbrella in the neighbourhood of the affected lithocyst, I am inclined to believe that in these cases the small lithocyst is one that has been reproduced to repair the loss of the original organ, which I suppose to have been removed by mechanical violence of some kind—a mutilation which seems well indicated both by the deficiency just alluded to of umbrella tissue in the parts concerned, and also by the cicatrix-like appearance which is presented at the confines of these parts by such tissues as remain. In conclusion, I may state that towards the end of August all the individuals of this species began to undergo a marked diminution in size. Concurrently with this diminution in size, the intensity of the pink colour—which in this species is characteristic of the ovaries, nutritive

[1] Extract from a paper on some new species and varieties of Medusæ, read before the Linnean Society on April 6th, by George J. Romanes, M.A.

system, and tentacles—underwent a marked decrease; so that at last I was only able to obtain specimens one half or one quarter the ordinary size of *Aurelia aurita*, and having nearly all their natural rose-pink colour discharged. I believe that these two phenomena—the loss of colour and the diminution in size—are related to one another in a very intimate manner. Just at the time of year when these two phenomena began to manifest themselves, I observed that all the specimens of *Aurelia* I met with were infested by a species of crustacean, which lodged chiefly in the ovaries and nutritive canals. These crustaceans appeared to devour with avidity all the coloured parts of their hosts, and I think it was probably due to the ever-increasing numbers of these parasites that the size of the individuals composing the incoming generations of *Aurelia* continued to become more and more diminutive. I shall, however, attend to all these points more closely next year, after which I shall doubtless be able to speak with more certainty regarding them.

SCIENTIFIC SERIALS

American Journal of Science and Arts, March.—In this number Mr. Trouvelot directs attention to the phenomenon of what he calls "veiled solar spots." During last year, the chromosphere has been notably thinner than usual, and the granulations smaller and less numerous, rendering more conspicuous the light-grey coloured back-ground between the granules. The veiled spots are seen through the chromosphere that is spread over them like a veil; they are, like ordinary spots, true openings of the photosphere; they are scattered throughout all latitudes, though more complicated in regions where the ordinary spots make their appearance. Mr. Trouvelot has observed spots at least within 10 degrees of the north pole of the sun (very few of the ordinary spots have hitherto been observed beyond 40).—Prof. Kimball describes an ingenious arrangement by which he demonstrates that the law affirming the coefficient of friction on an inclined plane to be constant for all velocities, is not strictly true. The sliding box had a cover 6 feet long, with strips of smoked glass upon it, on which a tuning fork, fixed above to an independent support, traced a wave-line as the box slid down, thus giving a perfect autographic register of the experiment.—A new method of measuring the velocity of electricity is described by Prof. Lovering. He avails himself of Lissajous' method of compounding the rectangular vibrations of two tuning forks, the reflected beam entering a telescope. The forks being maintained in vibration by electro-magnets and brought into unison, the resultant orbit seen in the telescope is invariable. A length of resistance coil is introduced sufficient to change the orbit to some other in the series, and this change reveals the amount of retardation of the one fork's vibrations, due to the inserted resistance.—Prof. Mallet discusses the constitutional formulæ of urea, uric acid, and their derivatives.—A new trilobite, *Dalmanitis dentata* is described by Dr. Barrett, and Prof. Marsh gives (in an appendix) the principal characters of *Tillodontia*, a new order of extinct mammals found in the Eocene deposits of North America.—Mr. Wallace gives an account of some flint implements found in the stratified drift in the vicinity of Richmond, Virginia, and there are one or two notes on points in American geology.

Poggendorff's Annalen der Physik und Chemie, No. 12, 1875.—A few years ago, separate researches were published by Narr and Stefan, on the conduction of heat in gases. M. Winkelmann here extends the inquiry, his object having been to ascertain how far production of currents and radiation affected the velocity of cooling, to study the behaviour of more gases, in order to a fuller comparison with theory, and to determine the dependence of heat-conduction of gases on temperature (the last is reserved for another paper). His apparatus was substantially like Stefan's, and he examined ten gases. The numbers obtained differ considerably from those of Narr, in whose experiments, he thinks, currents had not been avoided, and had contributed not a little to the velocity of cooling. Stefan's value for air is 6 per cent. greater than the author's, and this difference is explained by radiation, which Stefan had not taken into account.—M. Weber studies the coloured products obtained through the action of sulphur and selenium on sulphuric acid anhydride. He has got from this action a new oxygen compound of sulphur and a corresponding substitution product of selenium. The former contains twice as much sulphur as sulphuric acid (57·14 per cent.), and the formula assigned is $S_2 O_3$. M. Weber proposes for it the name of *sesquioxide of sulphur*, or *dithionoxide*. In the dry state it forms bluish-green crystals, and is like malachite in structure. Liquid only in the moment of production, it soon solidifies and cannot be fused again without decomposition. In a cool chamber, decomposition occurs but slowly. The selenium compound is denoted by the formula Se SO_3 (it requires 49·68 per cent. selenium, 20·12 per cent. sulphur.) The crystallised solid is of a dirty green colour, and it is much more stable than *dithionoxide*.—Before his death, Prof. J. J. Muller was engaged in experimenting on the influence of insulators on induction; and he communicated to Dr. Fiedler the following results. (1) Insulating media exercise, on the strength of induction, the opposite influence to the induced magnetism of the conductors. (2) Static electricity accumulated on insulators, exerts an influence on the strength of induction. Dr. Kleiner here gives details of the experiments, from which these conclusions were formed.—In a paper on thermo-electricity, M. Kohlrausch considers that for a theory of the phenomena, we do not need an immediate action of the contact surfaces, but can arrive at full agreement with the facts by assuming electromotive forces in the interior of the conductors, the places of contact having only a secondary influence. In every thermopile, when in action, there necessarily is, with the difference of temperature, a streaming over of heat from the hotter to the colder junction. The difference of temperature of the soldered parts has hitherto been thought the cause of the electromotive force; but with equal right we may take as basis the other inseparable circumstance, and suppose that with a heat current in a determinate mass, dependent on the nature of the conductor, an electric current is connected (provided that other electromotive forces are first excluded). These ideas are developed in the paper.—M. Holtz communicates the results of various attempts to improve the simple "influence" machines; and Prof. Lommel furnishes an elementary treatment of some optical problems, the smallest deflection in the prism, the achromatic prism, and the elementary theory of the rainbow.—M. Edlund deals with two objections to his unitarian theory of electricity; one by Prof. Newman, that to explain unipolar induction, the presence of at least two electric fluids is necessary; the other by M. Baumgartner, that the unitarian theory seems to contradict the supposition that vacant space has no conductivity for the galvanic current.—M. Sadebeck contributes some mineralogical studies from Kiel University; and among other subjects treated in this number are, the behaviour of electricity in electrolytes (Budde) and the alteration of the velocity of light in quartz through pressure (Mach and Merten).

Memorie Della Societa degli Spettroscopisti Italiani, Sept. 1875.—Prof. Tacchini continues his detailed remarks on sun-spots and faculæ observed by him at Palermo in 1873. The spectral lines of the prominences in the neighbourhood of faculæ are also fully given, the lines which appear to have been seen in nearly every eruption are D, $b^1 b^2 b^3 b^4$, 4,943, 5,031, and 5,316; the other lines less frequently seen are 5,263, 5,272, 5,282, 5,226, 5,232, 5,234, and 5,195.

Oct. 1875.—Prof. Tacchini gives a note on his observations in the previous number, and remarks the greater number of eruptions of magnesium on the western limb than on the eastern; the numbers on the former being more than double those on the eastern. The actual numbers for each month in 1873 are given. The number of eruptions in the northern and southern hemispheres are equal to each other. The zones of maximum eruptions appear to be between N. lat. 10° and 20°, and S. lat 0° and 10°.—Communications from Father Secchi, Prof. Dorna, and Prof. Tacchini on the partial solar eclipse of Sept. 29, 1875. It is remarkable that the first contact was observed by the spectroscopic method some seconds later than by the simple telescopes, and the last contact several seconds earlier.—Drawings of the solar prominences during the months of May and June 1874 by Secchi and Tacchini accompany this number.

Zeitschrift der Oesterreichischen Gesellschaft für Meteorologie, Dec. 1, 1875.—The concluding part of Herr Wild's paper on the late congresses appears in this number. Against what has been said of these gatherings, that their sole result would be the accumulation of millions of useless observations upon the millions that have already been published, he contends that in his opinion observations are useless only when they are faulty and inaccessible; and that he has found himself hampered, not by their great quantity, but by their deficiencies, inconvenience of form, or variety of arrangement. It is true that out of millions of figures perhaps only some thousands prove of value to the investigator; but who can decide which will and which will not eventually be used? Registers intended for publication are submitted to a more careful revision than those preserved only

in manuscript. Indeed, Dr. Wild would almost lay it down as a rule that unpublished observations should be deemed scientifically useless. As to congresses, he does not think that they should be occupied with discussions on the laws of meteorology. The derivation of laws from observations should be looked for in the undisturbed thoughtfulness of individuals. Experience shows, however, that private persons do not employ themselves as much as formerly in working out observations, and it seems to be absolutely necessary for the advancement of meteorology that every official observer should be given sufficient time, beyond that required for mechanical work, for developing the science as far as his powers will permit, and that the central institutions should be adequately endowed for this purpose.—The next paper is a review, by Dr. Hann, of the publications of Messrs. Fjord and Paul la Cour on the climate of Denmark, which contain very valuable statistics in the decennial means of fourteen stations. As in other similarly situated countries, both the heat of summer and the cold of winter are more intense inland than on the coasts, and in July the most easterly stations are the warmest. The mild weather of spring seems to advance from S.W. to N.E., and the cool weather of October from N.W. to S.E. Thus the mean temperature of 8° is reached in N.W. Jutland on the 11th, in Bornholm and the northern extremity of Rügen between the 23rd and 24th of October. The mean monthly range of temperature is greatest in May, least in January; from April to August the maxima rise higher above the monthly mean than the minima sink below it; from September to March the relation is converse. The absolute maximum range was registered in July, the absolute minimum in November. The average number of days on which frost occurs is ninety-two; time of maximum rainfall the latter end of August and beginning of September; of minimum, the beginning of April. Yearly mean rainfall—in Denmark, 604 mm.; on the west coast of Jütland, 670 mm.; at Copenhagen, 587 mm.; Bornholm, 580 mm.. A small table inserted here by Dr. Hann gives a great deal of information as to days on which rain fell, and on which thunderstorms, hailstorms, fog, and cloud occurred. January is the cloudiest, May and July are the least cloudy of months. Tables showing the frequency per cent. of the different winds and the monthly barometric pressure close Dr. Hann's summary of the valuable work under review.—In the Kleinere Mittheilungen, Dr. Gustav Hellmann states the chief results of his inquiries into the distribution of thunderstorms in Northern Germany. In general the annual mean number of thunderstorms in Germany increases from N.E. to S.W. It is least on the coasts of the Baltic, particularly in East Prussia greatest in the district of the Upper Rhine. On the eastern coast of the Baltic about twelve are observed in the year; on the western coast of the Baltic, sixteen; and on the coast of the North Sea, fifteen. Inland, the number averages twenty. They increase in number with increasing altitude, up to about 1,400 m., then decrease rapidly. Winter thunderstorms are much more common in Northern Germany than in Austria and Hungary.

SOCIETIES AND ACADEMIES

LONDON

Royal Society, March 30.—"An Experiment on Electro-Magnetic Rotation." By W. Spottiswoode, M.A., Treas. and V.P.R.S.

The phenomena of the rotation of movable conductors, carrying currents, about lines of magnetic force, are well known. One form of experiment, commonly called the rotating spark, presents, beside the actual rotation, some peculiar features which do not appear to have been noticed in detail.

The spark, when carefully observed, is seen to assume a spiral form; and the spiral is right-handed or left-handed according to both the direction of the current and the magnetic polarity. This effect is particularly noticeable if the magnetic pole be inserted only a short distance beyond the ring. The discharge is then seen to spread itself out sheetwise on the ring in the direction in which rotation would take place. The edge of the sheet is in the form of a helix.

The object of the following observations is to bring out the character of this phenomenon by making it a principal instead of a secondary feature of the experiment.

The arrangement here described consisted in using the poles of an electro-magnet as the terminals of a discharge from an induction-coil, and in observing the effect on the form of the discharge caused by exciting the electro-magnet. For this purpose the movable poles were insulated from the main body of the magnet by interposing a sheet of ebonite thick enough to prevent the passage of the discharge. The discharge was then effected either in the open air or in a closed chamber. The latter was constructed of a short cylinder of glass, say 3 inches in length and 2 in diameter, having conical ends pointed inwards, so as to receive the poles of the magnet. The chamber was also furnished with a pipe and stop-cock for the purposes of exhaustion.

The discharge from an induction-coil taken in air or other gas at atmospheric pressure, consists, as is well known, primarily of the spark proper or bright line, irregular in form and instantaneous in duration. But beside this, when the primary wire is thick and the battery-current strong, the spark is enveloped in a bright cloud, or rather flame, which is capable of being thrown on one side, although not entirely detached from the spark by a current of air. This, when examined in a revolving mirror, is found to be subsequent in time to the spark proper, and may be considered to be due to the gas in the neighbourhood of the spark becoming sufficiently heated to conduct part of the discharge, and to the consequent combustion of any extraneous matter floating in the medium. Such a view is supported by the fact that the colour of this flame depends partly upon the nature of the gas in which the discharge takes place, and partly upon that of any volatilisable matter which may be introduced near the poles.

The exciting of the magnet produces upon the spark proper no appreciable effect; but as soon as the flame is submitted to its action it is spread out into a sheet, which arranges itself in a helicoid right-handed or left-handed according to the direction of the current and of the magnetic polarity in obedience to Ampère's law.

Effects substantially the same are produced whether the discharge be taken in gas at atmospheric or at a less pressure. But in the former case the helix has a lower, in the latter a steeper gradient; that is to say, in the former case it presents a greater, in the latter a less number of turns, for a given interval between the poles.

Various gases were tried—atmospheric air, carbonic acid, ether, chloroform, coal-gas, hydrogen. Of these the first two succeeded best. With air the illumination of the flame-sheet was rather greater; but with carbonic acid greater steadiness of position was obtained. With both ether and chloroform, occasional flashes, brilliantly illuminated, were seen; but some chemical action appeared to take place militating against the steady development of the flame-sheet. With coal-gas there was an inconvenient deposit of carbon upon the sides of the chamber. With hydrogen the cloud was not sufficiently developed.

The success which attended the experiment with air may possibly be partly due, as suggested above, to the combustion of the extraneous matter floating therein; and in fact the brilliancy and extent of the sheet may be increased by attaching a piece of metallic sodium to the negative terminal, or by causing a stream of any of the chlorides in powder, *e.g.*, of strontium, lithium, &c., to flow across the field of action.

When a piece of sodium (or better still of soda) is attached to one of the terminals, two effects may be noticed. When that terminal is negative the whole of the flame is bright yellow, showing that the sodium is not only detached but even carried across the field and deposited on the positive terminal. When, however, the terminal, to which the sodium is attached is positive, it is found that the flame, when observed through a red glass, appears yellow to a certain distance from the (positive) terminal to which the sodium is attached, but red beyond; and also that the pitch of the helix is less near the position than near the negative terminal. These effects may be attributed to the presence of metallic vapour evolved by the heat at the positive terminal, but not carried across the field as when the terminal in question is negative.

The following explanation of the phenomenon, from which the mathematical part is omitted, is due to Prof. Stokes. Supposing the magnetic field to be uniform, the lines of force will be straight lines from pole to pole. In such a condition everything being symmetrical no rotation would take place. But if through any local circumstance the path of the current be distorted and displaced, then each element will be subject to two forces, one tending to turn the current round the axis, the other tending to make it follow the shortest path so as to diminish the resistance.

And the general nature of the phenomenon may be described as follows:—"First, we have the bright spark of no sensible

duration which strikes nearly in a straight line between the terminals. This opens a path for a continuous discharge, which being nearly in a condition of equilibrium, though an untranslatable one, remains a short time without much change of place. Then it moves rapidly to its position of equilibrium, the surface which is its locus forming the sheet. Then it remains in its position of equilibrium during the greater part of the discharge, approaching the axis again as the discharge falls, so that its equilibrium position is not so far from the axis. Thus we see two bright curves corresponding to the two positions of approximate rest united by a less bright sheet, the first curve being nearly a straight line, and the second nearly a helix traced on a cylinder of which the former line is a generating line.

"It was noticed that the sheet projected a little beyond the helix. This may be explained by considering that at first the discharge is more powerful than can be maintained, so that the curve reaches a little beyond the distance that can be maintained."

The appearance of the discharge when viewed in a revolving mirror (except the projection beyond the sheet, the illumination of which was too feeble to be observed) confirmed the above remarks.

Linnean Society, April 6.—Prof. G. Busk, vice-president, in the chair.—S. P. Agar, the Rev. R. F. Clarke, W. R. Guilfoile, Prof. H. A. Nicholson, J. Scully, and W. Waterfield were elected Fellows of the Society.—Dr. Day exhibited a Kingfisher and Unio, the former having been drowned by closing of the valves of the latter.—Mr. E. M. Holmes laid before the Society some rare mosses obtained in Kent. The localities, &c., of *Anacalypta cæspitosa*, *Seligeria paucifolia*, *Hypnum silesiacum*, *Dicranum montanum*, and *D. flagellare* were specially commented on.—Mr. Holmes also showed the root of *Thapsia garganica* var. *silphium*, which is said to possess a remarkable power of healing wounds; though a fatal root to horses and camels.—G. J. Romanes read an account of some new species, varieties, and monstrous forms of Medusæ (see p. 496).—Dr. Francis Day read a paper on some of the fishes of the Deccan, more particularly describing and critically treating of between fifty and sixty species, a few of which are new. Besides geographical range, questions of physiological import are touched on. He strongly recommends the "Masheer" (*Barbus tor*), to English pisiculturists as worthy of introduction into our rivers. This fish is well known, not only for the sport it affords the angler, but also for the excellence of the flavour of its flesh. It equals or even surpasses the salmon in size, but unlike the latter never enters salt water. It deposits its ova in the hill-streams. For these and other reasons he believes it well adapted for acclimatisation.—A second paper of Dr. Day's referred to the introduction of Trout and Tench into India. He stated it may now be concluded that the Loch Leven Trout (*Salmo levensis*), and the Tench (*Tinca vulgaris*), have bred there, and may prove an eventual success. A specimen of the Loch Leven trout reared in the Neilgherry waters was exhibited at the meeting. Its weight out of spirit 1¼ oz.; its greatest length 6¼ inches. Mr. Thomas, of the Madras Civil Service, in 1863, and Dr. Day in 1866, each attempted but unsuccessfully to carry out and hatch Trout ova in India; it was reserved for Mr. McIvor a few years later to succeed. The latter, in 1873, wrote, "all our fish are breeding rapidly," &c. The above specimen was caught January 1876. Dr. Day moreover remarks "whether trout will permanently succeed in Hindostan has yet to be solved."—Mr. C. H. Wade read some notes on the venous system of birds. These contained observations relating to abnormalities in their distribution in certain of our British songsters.—Dr. G. E. Dobson communicated a paper of Dr. J. D. McDonald's, on a new genus of trematoda, and some new or little known parasitic hirudinei. Resemblances between these groups are traced, though these are merely indicative of a representative relationship or one of analogy.—A paper entitled notes on Lowe's MS. list of Webb's type shells from the Canaries (1829), and on the annotations thereon of D'Orbigny (1839), and Lowe (1860), by the Rev. R. B. Watson, was briefly noticed by the secretary.—The following technical contribution was taken as read: A list of marine shells (ninety-five in all) chiefly from the Solomon Islands, with descriptions of several new species, by E. A. Smith.

Chemical Society, April 6.—Prof. Abel, F.R.S., president, in the chair.—The first paper read was a preliminary notice on the action of sulphuric acid on naphthalene, by Dr. J. Stenhouse and Mr. C. E. Groves. From amongst the products of the reaction the authors have succeeded in isolating two new isomeric compounds, which they call naphthalene sulphones.—Three notes from the Laboratory of the Yorkshire College of Science were then communicated by Prof. T. E. Thorpe, namely, On the action of the copper zinc couple on potassium chlorate and perchlorate, by Mr. H. Eccles; On thallium chlorate, by Mr. J. Muir; and On the isometric relations of thallium, by Mr. Thorpe himself.—Finally, Dr. H. E. Armstrong read a paper on the nomenclature of the carbon compounds, the discussion of which was adjourned until the next ordinary meeting, which will be on Thursday, April 20.

Zoological Society, April 4.—Prof. Newton, F.R.S., vice-president, in the chair.—Mr. H. E. Dresser exhibited and made remarks on a specimen of a hybrid between the Black Grouse and Hazel Grouse, belonging to Mr. J. Flower, and supposed to have been obtained in Norway. It had been purchased in the flesh in the London market.—Prof. Newton exhibited and remarked upon a copy of a Dutch translation of Pliny, containing a figure of the Dodo (*Didus ineptus*) and belonging to the Rev. Richard Hooper, which seemed to be an earlier edition of the same work which was formerly in the possession of the late Mr. Broderip, and was described by him in the Society's "Transactions" (vol. iv., p. 183).—Mr. R. Bowdler Sharpe exhibited a specimen of the true Swedish *Surnia ulula*, obtained many years ago at Amesbury, in Wiltshire, being the first recorded British-killed example of this species.—M. A. H. Garrod read a paper in which he gave a description of the organs and some of the most important muscles of the Darter (*Plotus anhinga*), from specimens which were recently living in the Society's collection.—Mr. Edward R. Alston read a paper on the genus *Dasyprocta*, and gave a description of a new species from Central America, for which the name *Dasyprocta isthmica* was proposed. The geographical range and synonymy of the other Agoutis were reviewed; *D. punctata* of Central America was regarded as distinct from *D. azaræ* of South Brazil, and *D. variegata* was shown to extend into New Grenada. In all ten species of Agouti were recognised as distinct.—A paper by Mr. P. L. Sclater and Mr. O. Salvin was read, in which they gave descriptions of fifteen new species of birds from Bolivia. Amongst these was a singular new form belonging to the Tanagridæ proposed to be called *Malacothraupis dentata*.—A second paper by the same authors contained a revised list of the Neotropical Anatidæ.

Royal Microscopical Society, April 5.—Mr. H. C. Sorby, F.R.S., president, in the chair.—A paper by M. Rénard, of Louvain, "On some results from a microscopical study of the plutonic and stratified rocks of Belgium," was read and illustrated by some beautiful chromo-lithographs. The paper chiefly dealt with the question of temperature at which these rocks had been formed, and the conclusions deduced from the presence of crystals and fluid in the cavities assigned 307° Centigrade as the probable heat at that period. The chairman expressed his great satisfaction that by a totally different process of reasoning M. Rénard had arrived at results so near to those which he had himself reached some years ago.—A paper by M. Brock, "On a new slip for mounting opaque objects," was communicated to the meeting by Prof. Rupert Jones.—A paper by Dr. J. J. Woodward, "On the markings of *Navicula rhomboides*," was read to the meeting by the Secretary. It was illustrated by a series of photo-micrographs, which deservedly called forth the admiration of all who examined them.

Anthropological Institute, March 28.—Col. A. Lane-Fox in the chair.—Mr. R. B. Swinton, was elected a member.—Capt. H. Dillon exhibited a collection of flint implements and arrow-heads recently made by him in the neighbourhood of Dytchley, Oxon.—Mr. E. B. Tylor, F.R.S., read a paper on Japanese mythology. The legends current in Japan are derived from three sources. Part belong to imported Buddhism, part are taken from Chinese mythology, and the remainder, to the ethnological interest of which the present paper called attention, are of native Japanese origin. It contains nature-myths of remarkable clearness, but distinct in their features from those of India, Greece, &c. Thus the episode of the Land-forming-god, who springs from the *asi* or flag which binds together the new-found marshy coast-land of Japan, belongs to what is, in fact, geology expressed in mythic language. Again, the birth of the Sun-goddess, and her transference to the sky as Ruler of Heaven, is followed by a graphic story of the visit paid to her by her brother, who is no doubt the personified Wind or Tempest, as

he is described as mild and gentle when unprovoked, and always with tears in his eyes (*i.e.*, rain), but when resisted he bursts into uncontrollable fury, uprooting trees and devastating the world. Frightened with his violence, his sister, the Sun-goddess, retires into a cave in the sky, closing the entrance with a rock, and leaving the world in darkness. By the advice of the god of Thought, a fire is kindled and dances performed outside, and the sacred mirrors and pieces of cut paper (*go-hei*) which still form the furniture of a *Sin-to* temple, are displayed. The Sun peeps forth, and is then pulled out altogether, and the cave closed. The whole episode is evidently a mythic picture of the Sun hidden in tempest in the clouds as in a cavern, till she comes forth again to enlighten the world.—A paper on the term "Religion" was read by Mr. Distant. He said that the possession or non-possession of religion, and the nature of the religion possessed were usually made by our leading anthropologists tests of development in civilisation and culture. But accounts are often untrustworthy, and depend upon the bias of the inquirer. Also, "Religion" is an undefined term; scarcely two writers on culture agreeing on the subject. Indeed, some of the religious ideas of savages are found to be held by eminent men. A term required to be used, that was alike capable of being conceived and incapable of being misunderstood.—In the discussions Mr. Tatui Babo, Mr. Conway, Mr. Moggridge, Mr. Bouverie Pusey, Mr. Jeremiah, and others, took part.

Institution of Civil Engineers, March 28.—Mr. Geo. Rob. Stephenson, president, in the chair.—The first paper read was on sewage interception systems, or dry-sewage processes, by Mr. Gilbert R. Redgrave.—The second paper read was on the treatment of sewage by precipitation, by Mr. W. Shelford.

PARIS

Academy of Sciences, April 10.—Vice-Admiral Paris in the chair.—The following papers were read:—Experimental critique on the formation of sugar in the blood, or the function of physiological glycæmia, by M. Cl. Bernard.—Analytical solution of the problem of distribution in a magnet, by M. Jamin.—Vegetation of maize commenced in an atmosphere without carbonic acid, by M. Boussingault. The grain, germinating, produces a fertile atmosphere (*i.e.*, one containing carbon), in which, with aid of light, the leaves organise chlorophyll, and then amylaceous and saccharine matters.—Verbal observations on the same subject, by M. Pasteur.—Seventeenth note on the electric conductivity of substances that are mediocre conductors, by M. Du Moncel. The substances here studied are the stems of certain shrubs, and the human body. The conductivity of the former varies with the mode of application of the electrodes, the nature and thickness of the bark, and the season. The resistance of the human body between the wrists is estimated at 350 to 220 kilometres. But when the skin is dry, and at the commencement of an experiment, it may exceed 2,000 kilometres.—Experiments on the schistosity of rocks; geological consequences that may be deduced, by M. Daubrée. The geometrical arrangement of the leaves of crystalline masses and Jurassic layers above them in various central formations of the Alps (Mont Blanc), are explained, through experiment, as the effect of flow of a mass which was not completely solid.—Discussion of barometric curves continued from March 7 to 14, 1876; best process for comparing the course of the temperature and the pressure, by M. Sainte-Claire-Deville.—On the *trombe* of Heiltz-le-Maurupt (Marne), Feb. 20, 1876. Two persons witness that the *trombe* descended; the windows of the town-hall were broken inwards, which is against the suction-hypothesis, as is also the fact that the circle of mechanical action was very distinctly circumscribed.—On the displacement of lines in the spectra of stars, produced by their movement in space (continued), by P. Secchi.—M. Borchardt was elected correspondent of the Academy in the section of geometry, in place of M. le Besgue.—Velocity of thermal flow in a bar of iron (second part), by M. Decharme.—On the solar spots and the physical constitution of the sun, by M. Planté. A horizontal sheet of filter paper, moistened with salt water, is connected above with the negative pole of the secondary battery; on bringing up towards it from below the positive electrode, a crater-like cavity is formed with torn edges projecting towards the + electrode (light and vapour also being emitted); and the aspect is very much that of sun-spots. M. Planté also studied the incandescent globules obtained in fusing thick metallic wires with a strong electric current of quantity, and draws a parallel between their structure and that of the sun.—Influence of the asparagine contained in saccharine juices (of beet and cane) on the saccharimetric test; destruction of the rotatory power of asparagine; method of determination, by MM. Champion and Pellet.—The elephants of Mount Dol; attempt at organogeny of the system of molar teeth of the mammoth (second communication), by M. Sirodot.—On the optical effects of lamellar snows floating horizontally, by M. De Fonvielle.—On the catastrophe of Grand Sable (district of Salazie) in the Isle of Reunion; second note by M. Vinson. He endeavours to show it was the work of subterranean fire, which prepared a normal eruption that followed.—Letter from M. Cassien on the same subject; he rejects the idea of volcanic action.—On the catastrophe of the Jabin pits (Feb. 4, 1876), by M. Riembault. Fine coal-powder, suspended in air, is explosive. In the Jabin pits a little fire-damp was probably first inflamed at a point, and this ignited the coal-powder, which, under high temperature, liberates its explosible gases. The galleries were found incrusted with coke, evidently the result of combustion of coal. The air of the miner's lungs, forming part of the explosive atmosphere, is inflamed with it.—On the hatching of the winter egg of Phylloxera; note by M. Balbiani. He succeeded in observing a young Phylloxera (April 9) immediately after hatching. He regards it as a fourth specific form of the animal.—On a compensating balance wheel for marine and other watches, by M. Winnerl.—On the theory of the proof plane, by M. Bouty.—Note on the coloured rings produced by pressure in gypsum, and on their connections with the coefficients of elasticity, by M. Janettaz.—On the employment of Gramme's magneto-electric machines for lighting the large halls of railway stations, by M. Sartiaux.—Simple apparatus for the analysis of gaseous mixtures by means of absorbent liquids, by M. Raoult.—On exchange of ammonia between natural waters and the atmosphere, by M. Schloesing.—On the products of reduction of anethol, and on the probable constitution of this substance, by M. Landolph.—On change of the volume of organs in its relations to circulation of the blood, by M. Franck.—Researches on the functions of the spleen, by MM. Malassez and Picard. Iron appears to be, in the spleen, purely and simply in the state of hæmoglobin the same as that of the blood.—The physiological relations between the acoustic nerve and the motor apparatus of the eye, by M. Cyon.—On the embryology of Nemertina, by M. Barrois.—Osteological characters; observations on the persistence of the intermaxillary in man, by M. Roujou.—Action of sulphide of carbon on an insect which attacks the plants of herbaria, by M. Schnetzler.

BOOKS RECEIVED

BRITISH.—Geological Sketches: L. Agassiz (Trübner and Co.)—The Secret of the Circle, its Area ascertained: Alick Carrick (Henry Sotheran and Co.)—The Intellectual Development of Europe: J. W. Draper. 2 vols (George Bell and Sons).—Sport in Abyssinia: Earl of Mayo (John Murray).—The Year-Book of Facts, 1876: C. Vincent (Ward, Lock, and Tyler).—Animals and Plants under Domestication, 2nd edition: Charles Darwin. 2 vols. (John Murray).—Vital Motion as a Mode of Physical Motion: Dr. Radcliffe (Macmillan and Co)—Philosophy without Assumptions: T. P. Kirkman, F.R.S. (Longmans)—Diseases of the Nose: Spencer Watson, F.R.C.S. (H. K. Lewis).—Discoveries in New Guinea: Capt. John Moresby (John Murray).—Problems and Examples in Physics, an Appendix to Ganot's Elementary Physics (Longmans).

THURSDAY, APRIL 27, 1876

"SCIENTIFIC WORTHIES"

VII.—SIR CHARLES WHEATSTONE, BORN FEBRUARY 1802, DIED OCTOBER 19, 1875

CHARLES WHEATSTONE was the son of a music-seller at Gloucester, where he was born in February 1802, and was educated at a private school in that city. His father afterwards came to London, where he became a teacher of the flute. He had, we bel eve, some share in the musical education of the Princess Charlotte, a fact of which he was never tired of boasting. In 1823 young Wheatstone removed to London and commenced business as a musical instrument maker, and in the same year made what was probably his first contribution to scientific literature in a paper entitled "New Experiments on Sound," contributed to Thomson's "Annals of Philosophy." In 1827 he contributed to the *Quarterly Journal of Science* an account of "Experiments on Audition," and a description of the beautiful toy known as the Kaleidophone. In 1832 he read an important paper to the Royal Society, "On the Acoustic Figures of Vibrating Surfaces." In this memoir the author gave for the first time the laws of formation of the varied and beautiful figures discovered by Chladni. He continued for several years to devote his attention to Sound, and subsequently to Light. He was appointed Professor of Natural Philosophy in King's College, London, in 1834, and in the same year made his celebrated experiments on the velocity of an electric discharge by the aid of revolving mirrors. Wheatstone does not seem to have lectured regularly at King's College, and many of his discoveries were described to the world by Faraday at the Royal Institution. Indeed he was not well adapted for public lecturing; he was so nervous that even in a very small company he usually sat silent. Though his discoveries have become of such immense practical importance, Wheatstone himself was far from being a practical business man; on this account he often failed to reap the substantial fruit of his discoveries. Wheatstone was married on Feb. 12, 1847.

Wheatstone's name is intimately connected with the early history of Spectrum Analysis. In a paper read in 1835, "On the Prismatic Analysis of Electric Light" at the Dublin meeting of the British Association, he announced the existence of rays of definite refrangibility, emitted in the volatilisation of metals by the electric spark. He showed that the spectrum of the electric spark from different metals presented each a definite series of lines differing in colour and position from each other, and that these appearances afforded the means of distinguishing the smallest fragment of one metal from that of another. "We have here," he wrote, "a mode of discriminating metallic bodies more readily than that of chemical examination, and which may hereafter be employed for useful purposes." These last words furnish the keynote to all Wheatstone's work; however valuable may be the services he has rendered to pure science, his great ultimate aim was the useful and practical. It was at the meeting of the British Association in 1838 that he described and exhibited the newly-invented stereoscope, and at the 1848 meeting he described his "polar clock," an instrument for ascertaining the time by means of the change in the plane of polarisation of the light of the sky in the direction of the pole. One of these instruments, we believe, has been sent out with the Arctic Expedition. Wheatstone's description of the rheostat, and of the well-known "bridge" which bears his name, is printed in the *Transactions of the Royal Society* for 1843. Indeed, it is a popular error to suppose that Wheatstone's scientific fame rests solely on his connection with the electric telegraph; he would have deserved an honourable place in the annals of science had this practical application of electricity been yet undiscovered. In the Catalogue of the Royal Society alone will be found the titles of upwards of thirty papers by him, not to mention many others scattered about in various publications.

The President of the Italian Society of Science, of which he was made an honorary member in 1867, said, in conferring the honour, that the applications of the principle of the rotating mirror are so important and so various that this discovery must be considered as one of those which have most contributed in these latter times to the progress of experimental physics. "The memoir on the measure of electric currents and all questions which relate thereto and to the laws of Ohm has powerfully contributed to spread among physicists the knowledge of these facts and the mode of measuring them with an accuracy and simplicity which before we did not possess. All physicists know how many researches have since been undertaken with your rheostat and with the so-called 'Wheatstone Bridge,' and how usefully these instruments have been applied to the measurement of electric currents, of the resistance of circuits, and of electro-motive forces."

With regard to the scientific value of the revolving mirrors, M. Dumas spoke as follows in the address which he gave at the obsequies of Wheatstone in Paris:—"This admirable method enabled Arago to trace with a certain hand the plan of the fundamental experiment which should decide whether light is a body emanating from the sun and stars or an undulating movement excited by them. Executed by an accomplished experimenter, it proved that the theory of emission was wrong. This method has then furnished to the philosophy of the sciences the certain basis on which rest our ideas of the nature of the forces, and especially of that of light. By means of this or some other analogous artifice, we can even measure the speed of light by experiments purely terrestrial, which, pursued by an able physicist, have guided the measure of the distance between the earth and the sun."

As to Wheatstone's connection with the electric telegraph, it is unnecessary for us here to speak, as this was so fully gone into in the series of articles on "The Progress of the Telegraph," in vols. xi. and xii. of NATURE. De la Rive, in his "Treatise on Electricity," (Part VII., Chap. I.), states so fairly Wheatstone's connection with telegraphy, that we quote here what he says:—

"The philosopher who was the first to contribute by his labours, as ingenious as they were persevering, in giving to electric telegraphy the practical character that it now

possesses, is, without any doubt, Mr. Wheatstone. This illustrious philosopher was led to this beautiful result by the researches that he had made in 1834 upon the velocity of electricity—researches in which he had employed insulated wires of several miles in length, and which had demonstrated to him the possibility of making voltaic and magneto-electric currents pass through circuits of this length. It was in 1837, in the month of June, that Mr. Wheatstone took out his first patent. He first employed five conducting-wires, between two distant stations, acting upon five magnetised needles, the movements of which, being combined two and two, were enabled to produce several different signs. Mr. Wheatstone, at this time, entered into partnership with Mr. Cooke, who had likewise devised an ingenious telegraphic apparatus founded upon the same principles. The English philosophers, from the very first, had added to the telegraph—properly so called—an apparatus intended to call the attention of the observers, and designated under the name of *Alarm*. . . . The principle upon which this alarm is founded includes an immense number of applications, for it enables man to put in action—at any distance whatever—all the forces of mechanics, in an instantaneous manner. Indeed, more recently. Mr. Wheatstone applied it to the construction of his dial telegraph; and it is the same principle which serves as the basis of Morse's telegraph, invented at nearly the same period."—*De la Rive*, Part VII. Chap. I.

We may repeat here a fact which does not appear to be generally known or recognised, that Wheatstone was the first suggester and worker at submarine telegraphy. From documents before us we learn that so early as 1837 he was thinking much on and was greatly interested in the subject; and in February, 1840, he stated his opinion before a Select Committee of the House of Commons as to the practicability of establishing electric communication by means of a cable between Dover and Calais.

Wheatstone's applications of electricity were almost innumerable. His electric clocks are well known; various electric registers were invented by him, one especially for recording a variety of meteorological data, and another, which acts as a chronoscope to register the velocity of a bullet. Indeed, his ingenuity was marvellous, and, as we have already hinted, there are doubtless many useful inventions due to him, of which he has reaped neither the profit nor the credit.

Wheatstone received many "honours" during his lifetime. He was made a Fellow of the Royal Society in 1836, in 1868 he was knighted, in 1873 he was elected a foreign member of the Paris Academy, and had altogether upwards of thirty foreign distinctions. The following estimate of Wheatstone and of his contributions to science is from the pen of Signor Paul Volpicelli, the distinguished Italian electrician.

The Academy of Sciences of the Institute of France, at its *séance* of October 18, 1875, was informed by the perpetual secretary, M. Dumas, that the illustrious English physicist, Charles Wheatstone, was seriously ill in Paris at the Hôtel du Louvre. By the 17th of the month, however, fears for the safety of that *savant* were well nigh vanished, and it was believed that he would soon be completely restored to health. The hope unhappily proved fallacious; an aggravation having occurred in the pneumonitis, which was thought to have been overcome, carried off that distinguished physicist on the 19th of the month from his friends and from science.

Our Reale Academia dei Lincei was profoundly afflicted at this irreparable loss, which deprived it for ever of one of the most celebrated of its foreign correspondents, who was and will continue to be one of the proudest and most pure scientific glories, not only of England, but of the whole civilised world, since science does not know nationalities, but belongs to all countries.

The brilliant Wheatstone inevitably became possessed of all those honours which science is wont to confer on her eminent votaries, and in 1875 he obtained from the Academy of Sciences of the Institute of France a title of the highest distinction, that, viz., of one of the eight Foreign Associates. Among the cultivators of physics the name of Wheatstone will never be forgotten; neither the present nor the future can forget his rare penetration, the inventiveness of his genius, his discoveries, and the uncommon ability with which he reproduced in machines the phenomena of nature.

His name will be as that of a star to whose light will turn the minds of those who desire to comprehend the progress of physical doctrine. In doing honour to the memory of this our illustrious foreign correspondent, it will be best to record his scientific labours, which are all of the highest interest.

In the present short obituary notice we shall merely give a rapid sketch of the principal physical researches of the illustrious deceased.

Our countryman, Leonardo da Vinci, in 1500, or thereabouts, conceived and was the first to affirm, that from a picture it was not possible to obtain the effect of relief. But Wheatstone, reflecting profoundly in 1838, on the physiology of vision, invented the catoptric stereoscope, with which he philosophically solved the problem of the optical and virtual production of relief.

This instrument was a converted *dioptric* of the father of modern optics, the distinguished Brewster, and at the same time was more simple, more popular, and more elegant. Continuing to study the physiology of vision, Wheatstone succeeded in constructing the diaphragmatic stereoscope, *i.e.* without mirror and without lenses, but merely with a diaphragm. With this instrument there could be received coexistently on the retina three images, two, viz., one photographic, and one in relief, produced from the first two.

The diaphragmatic stereoscope manifested, better than the two others, the physiology of vision; it was published in the "Atti dell. Academia Pontificia dei Nuovi Lincei," t. vii. p. 219, and in the work entitled "Monographie du Stereoscope," by H. De la Blanchère (Paris, 1861), as also in the *Cosmos*.

The use of the stereoscope, whether catoptric, dioptric, or diaphragmatic, would have remained pretty restricted, if photography had not come in to greatly extend that use, in its application to industries, arts, and sciences.

When one undertakes to study the hyperoptics, it often happens that the vibrations of the molecules of ether, constituting a luminous wave, are found difficult to conceive,

To remove this difficulty, Wheatstone invented a very ingenious apparatus, by which the vibratory motions of the luminiferous ether could be represented with considerable fidelity, and especially the phenomena of polarisation, whether rectilinear, circular, or elliptic.

Many were the achievements realised by Wheatstone in applying himself to optics: we owe to him the invention of a kaleidoscope, in which the persistence of impressions on the retina was utilised in demonstrating the transversal vibrations of an elastic rod fixed at one of its extremities; we owe to him one of the most sensitive photometers, as also the way of estimating the duration of lamps, the movements of the sea, and the ramifications of the retina; the difference between the solar and the electric light, and the lines of the light obtained from combustion of bodies brought to the poles of the voltaic battery. He was, further, the inventor of the polar clock, an instrument designed to indicate the hours through observation of the plane of polarisation of light of the blue sky in the region of the North Pole. That instrument, improved by Soleil, was marvellously adapted for finding the neutral points of Arago, Babinet, and Brewster.

The science of acoustics also profited by the valuable researches of our Lincean correspondent, for he experimented on sound and on hearing, devised his kaleidophone, occupied himself with resonance or reciprocal vibrations produced by a column of air; he also studied the transmission of musical sounds, and the figures obtained with sand on a vibrating surface, or acoustic figures.

Moreover, he cultivated, with great advantage to science, electro-dynamics; and devised two rheostats, one for great, the other for small resistances.

We are indebted to the illustrious deceased for many other scientific contributions, which have realised a notable progress in various branches of modern physics, and especially in telegraphy. Among these contributions, which time would fail fully to enumerate, we must not omit to speak of the method, so fruitful of valuable consequences, by which Wheatstone determined the velocity of the electric discharge in a metallic wire.

He was likewise skilled and practised in ballistics; and he employed the uniform rotation of two pasteboard discs, fixed on a common horizontal axis passing through their centres, to ascertain the initial velocity of a projectile fired from a gun. The projectile, traversing with uniform velocity these rotating discs, produced within two holes, the different situations of which afforded a means of determining the initial velocity of the ball.

Wheatstone was the first to employ the rapid rotation of a reflecting disc for measuring the velocity of propagation of an imponderable agent, without resorting to great distances, such as the planetary. After having in vain turned the spark-exciting organ round an axis, hoping to be able to increase the extent of sparks, and also to alter their direction, according to the direction of turning, he conceived the idea of communicating to a reflecting disc or plane mirror a very rapid rotatory action, by which the electric spark produced at a certain distance from the disc might be reflected.

The interesting consequences derived from these experiments are—(1) that electricity takes an appreciable time in traversing a distance, whence may be inferred approximately the velocity of the electric current; (2) that this velocity does not depend on the direction of the electric current; (3) that of three sparks, reflected by this means, in the same horizontal direction, the two lateral ones appear contemporaneously, but the middle appears retarded with respect to the first, which fact is not reconcilable with the hypothesis of Franklin on the nature of electricity; (4) that the same method was adopted by the celebrated Arago, whose experiments lead to a decisive judgment which of the two theories on the nature of light, that based on emanation, or that based on ethereal vibration, must prevail.

The fact that we now possess methods of determining the velocity of light so practical, elegant, and speedy as those of the distinguished physicists Fizeau and Foucault, is due to the method of rotating mirrors, which was introduced through this order of researches of the English physicist, of whom we deplore being for ever bereaved; the fame of whose discoveries is everywhere—

> "And with the world itself shall still endure."
>
> Dante, *Inf.*, ii. v. 60.

P. VOLPICELLI

THE PROGRESS OF THE LOAN COLLECTION

VARIOUS are the trains of thought suggested by a visit to those galleries in which the science of the past and the present is being represented by so goodly an array of its working implements. If one has been at all in sympathy with the movement which is now so near its goal (and who that has in the least appreciated the progress and benefits of science can be out of sympathy with it?), it will, first of all, be truly gratifying to him to observe on every hand such manifest tokens of hearty co-operation in the movement. Even those who are engaged in marshalling the various treasures of the departments which have been entrusted to their charge seem to be animated with an unusual zeal (a zeal promising the best results), and, at first sight even, it is evident that the various museums and private collections in this country and on the Continent have been ransacked for some of their choicest contents to be sent to these South Kensington galleries, aiding the completion of an ideal which is true in its comprehensiveness. The nations of the Continent who were appealed to for their support of the scheme, have shown, many of them, by an activity which is beyond all praise, how warmly the proposal has been entertained. This is especially true of Germany. The Berlin Committee appointed a short time ago, and including some of the foremost names in science, while it gained also the useful accession of Imperial influence, promptly made application (the time was short) to the various Universities and Polytechnic Schools throughout the country, and they were met as promptly; so that soon quite a network of subordinate committees came into being, all working harmoniously towards the common end. The German contributions form a very considerable proportion of the whole; and they, in common with contributions from the Continent generally, are indeed surprising in their extent, if we consider the shortness of time allowed and the unique character of the exhibition. Both Germans and French have been doing all that they

can up to the latest moment, and this has somewhat retarded the arrangements. The Russian contributions have not yet been received. The collection of instruments from Italy is, in many respects, of a peculiarly interesting character.

A catalogue and a series of handbooks are in course of preparation. Some idea of the extent of the collections may be obtained from the fact that in the former there will be somewhere about 6,000 entries. The nature and value of the handbooks for the various departments may be learned from the fact that they are prepared by such men as Huxley, Henry Smith, Clifford, Maskelyne, Carey Foster, Guthrie, Clements Markham, Lockyer, and others. The entire work, extending to some 300 pages, in which the history and functions of the several instruments are dealt with, will be expounded in a clear and succinct manner.

It would be impossible, we imagine, to walk through those corridors and inspect the various objects encased on either hand, without soon beginning to marvel at the multiplicity and complexity of the tools which science has come to construct for herself in the progress of her inquiries; and at the degree of precision and skill to which she has at length attained, after many a tentative and faltering step towards the end in view. Yet it may truly be said, that as the branches and divisions of science multiply in increasing ratio, and therewith also the apparatuses become more and more complicated, the investigator, acquiring a deeper insight and wider range, ere long perceives a unity where he had not previously imagined it, and finds that many things which had seemed to be so many *disjecta membra* are knit together in the closest interrelations. It is perhaps not among the least benefits accruing from an exhibition like the present, that scientific men are enabled to survey, in close juxtaposition with their own line of research, other lines which they may have given little heed to, or but imperfectly comprehended. To an outsider also, who appreciates the keen enjoyment of scientific tastes, and is not hopelessly devoted to a hobby, the comparison cannot fail to be pleasant and instructive.

Again, that progress of science just referred to, from the less perfect to the more perfect, from the rough and clumsy to the finished and refined, in the construction of her instruments, affords a retrospect that is fascinatingly instructive. In the inspection of the collection one comes ever and anon upon some antiquated-looking instrument of plain proportions and great simplicity, which almost seems as though it had stumbled by mistake into the company of its elegant and brightly furbished conquerors—had come among a generation that knew it not. Yet these ancient relics have a deeply interesting history, and they will doubtless attract to themselves no small share of attention from the visitors who will take advantage, we trust, in large numbers, of the unique opportunities this exhibition affords. Nor would any contempt which might momentarily arise for the unpretentious and uncouth figure of these instruments be long in giving place to a sort of veneration and awe, for the story they have to tell that they took shape under the hand or at least under the thoughtful direction of a Galileo or a Herschel.

The general arrangement of the exhibition, which, as already mentioned, is by no means complete yet, may here be briefly indicated. The space occupied is in the West and South Courts. After passing through the South Court, in which stand the South Kensington Museum instruments, the Educational apparatus, and those relating to Applied Mechanics, the visitor enters the West Court, the northern portion of which contains the greater bulk of the present collection. Here in succession are arranged the departments of Magnetism and Electricity, Mathematics, Meteorology, and Astronomy. On proceeding upstairs and returning, the rooms devoted to Geography and Geology, Biology, Chemistry, and Physics, are successively passed through. This will indicate the general arrangement of the whole; but the classification of the various instruments in the catalogue now being prepared is considerably more detailed.

It is not our intention here to attempt anything like an exhaustive account of the various objects of interest which line these courts. In the Astronomical department will be seen several of Galileo's instruments, including two telescopes made by himself, one of which served for his most important discoveries and experiments. The object-glass is shown by which he discovered Jupiter's satellites, and first saw spots on the sun. The Reale Institute of Florence, to which the Exhibition is indebted for these instruments, has sent sundry other relics of the great astronomer, including a natural magnet, which he armed, and an air thermometer and microscope, which were his. Nor should we fail to be interested in such instruments as a quadrant of Tycho Brahé, some object-glasses and eye-pieces, which were mostly polished by Christian and Constantine Huyghens, and a telescope of Huyghens. A venerable wooden object near the wall is Sir W. Herschel's 7-feet telescope, both mirrors of which were finished by Sir William's own hands, and there is also shown a 10-feet reflecting Newtonian telescope also made by him. Several of Gravesande's instruments are shown; also the apparatus used by Baily in repeating Cavendish's experiments, Foucault's pendulum apparatus, Gauss's pendulum for demonstrating the rotation of the earth, &c. The more modern aids of astronomical observation are largely represented, and, among others, there is a beautiful transit instrument, of novel construction, from Germany.

Among the instruments of a mathematical order are Babbage's celebrated calculating machine, also two calculating machines constructed in 1775 and 1777 by James Black for Viscount Mahon. We might also note the integrating machine of Sir W. Thomson. The laws of combination of harmonic motions have been illustrated by some ingenious apparatus of Messrs. Tisley and Spiller, and by a machine invented by Mr. Donkin; but the most important application of these laws is to be found in Sir W. Thomson's tidal clock, and in a more elaborate machine which draws curves predicting the height of the tide at a given part for all times of the day and night, with as much skill as can be obtained by direct observation. Then there are the "Napier bones" of the inventor of logarithms, used for performing multiplication and division. Among measur-

ing instruments the gauges lent by Sir Joseph Whitworth are remarkable for their delicacy. With one of these, for measuring the bore of guns, differences of one-ten-thousandth of an inch can be measured. There is another, moreover, by means of which a quantity so minute as one-millionth can be grasped. The apparatuses which Joule employed in ascertaining the mechanical equivalent of heat, are among the collection.

The field of magnetism and electricity is now a very vast one, and in the exhibition it is represented by a correspondingly large variety of apparatus. A peculiar halo of interest gathers round the instruments, many of them so simple and homely, with which Faraday worked out his fruitful ideas. Among old electric machines is one with two glass cylinders, one of which is covered with sealing-wax, so as to obtain both positive and negative electricity; there is also Nairne's early electric machine with glass globe, Armstrong's hydro-electric machine, &c. Volta's electric lamp is exhibited for lighting gas by means of the electric spark. There is an endless variety of batteries, and the numerous Holz and other electric machines exhibited will afford material for careful study, as also the novel forms of magneto-electric and other machines which have of late years multiplied so fast. Here may be found apparatus for regulating the time and place of an electric discharge; apparatus for accumulating electricity; apparatus for observing the effects of discharge of accumulated electricity; apparatus for producing, and apparatus for observing, effects of continuous electric currents; apparatus for measuring the strength of electric currents, and apparatus for measuring resistance, and so on. In the telegraphic department there is a complete historical collection which must be of great interest not only to electricians and telegraphists, but to the general public, illustrating the progress of the electric telegraph from the time when the first idea of it was crudely embodied, down to the present time. This collection includes, of course, all the classical apparatus which belonged to Wheatstone and Cooke, among which is the original Wheatstone Bridge. Many will be interested in seeing the instruments that were used on board the *Great Eastern* in laying the Atlantic Cable. There are copies of the first German telegraphic apparatus (Goemmering's), and the first needle telegraph (Schelling's); the electro-magnetic telegraph apparatus used by Gauss and Weber in Göttingen, from 1833 to 1838, &c., &c.

We must here desist for the present, though the majority of the sections are still unvisited. It may be understood, even from these hasty and imperfect notes—but in any case, the reader may soon convince himself by personal inspection—how rich and varied is the collection now in course of completion, and how ample is the feast therein provided for those who feel in any measure drawn to the "beautiful and true" in science.

The date of opening of the exhibition is still uncertain. It is hoped that her Majesty will grace the occasion with her presence, and conduct the opening ceremony. Some of the galleries of the exhibition will probably be lighted in the evenings with the electric light, and a considerable portion of the apparatus, it is intended, will be kept in motion.

GREEN'S GEOLOGY

Geology for Students and General Readers. Part I. Physical Geology. By A. H. Green, M.A., F.G.S., Professor of Geology in the Yorkshire College of Science, &c. (London: Daldy, Isbister, and Co., 1876.)

THE progress of geological research in every quarter of the globe is exceedingly rapid, and discoveries of new processes of investigation, leading to the opening up of fresh lines of thought in connection with the science, are constantly taking place. Hence, in spite of the acknowledged excellence of some of the existing manuals of geology, such as those of Lyell and Jukes, we cannot but hail with pleasure the appearance of a new text-book of the science—especially of one which, like the present work, is not a mere epitome of one or other of the standard treatises just referred to, but which aims at some originality in its arrangement and mode of treatment of the subject. Prof. Green may be congratulated on having written a work embodying a vast amount of valuable information, which is presented in a very clear and readable form.

Of the two classes for whom Prof. Green writes, we think the "general readers" are those for whom his work is best adapted. Some of the chapters, such as the ninth, which is entitled, "How the rocks came into the positions in which we now find them," and the tenth, of which the heading is, "How the present surface of the ground has been produced," are models of clear and accurate description, and of logical and forcible reasoning; they are evidently written by a man with a thorough acquaintance with his subject, and no little enthusiasm for it to boot. We may, perhaps, demur to the confident tone and the sometimes off-hand manner with which our author disposes of the objections of those who differ from himself on some of the questions discussed; yet we cannot but feel that the conclusions at which he has arrived and which he so clearly states, are the result of independent observation and personal conviction, and are not merely adopted at second-hand. While reading many parts of this work, it is impossible to avoid the consciousness that we are following the pleadings of an advocate, and not the expositions of a judge; yet the arguments are brought forward with such lucidity and earnestness, that we accept the work as embodying the ablest exposition yet offered to us, of the views of that school of geologists to which Prof. Green belongs. Occasionally, however, the author is so carried away by his enthusiasm in behalf of favourite doctrines, that his confidence becomes something very like arrogance, as in the following passage, with which he concludes his chapter on Denudation:—

"The reader will do well to compare with the theory of surface-sculpture upheld in the preceding memoirs, chapter xix. of the late Prof. Phillips' 'Geology of the Valley of the Thames.' Elegant and ingenious as is the explanation there put forward, there is about it an unsatisfactory vagueness and want of definition, which contrasts strongly with the sharp precision and logical coherence of the views on the subject of which a sketch has been attempted in the preceding pages, and which are steadily gaining ground among modern geologists."

In keeping apart from the other portion of his work purely speculative questions, and treating of them in two chapters *at the end* of the volume, we think the author

has exercised a very wise discretion. In these final chapters the reader will find an excellent summary of the latest contributions to Cosmogony, and a generally fair and impartial discussion of the bearing and value of recent geological theories.

Of the suitability of Prof. Green's work as a text-book for "students," we regret to say that we cannot speak so favourably. The ability and enthusiasm with which our author writes on certain portions of his subject, fail to reconcile us to his inadequate treatment and sometimes total neglect of others of equal importance; and, in perusing the book, it is impossible to avoid the feeling that the space devoted to the several subdivisions of the science must have been determined, not as the result of a judicial consideration of their respective claims, but almost entirely by the author's peculiar predilections. For example, it is rather startling to find in a work on Physical Geology, extending to 540 pages, no discussion whatever of the phenomena and origin of mineral veins, and only, indeed, an incidental mention of their existence!

A still more serious blemish of the work, considered as a student's manual, is the looseness of description and inaccuracy of language in certain parts of it. This defect is most conspicuous in the second chapter, which treats of the characters and classification of rocks, and which offers a painful contrast to those later chapters of which we have already spoken. Among the numerous grave errors which every petrologist will remark in this chapter, we may call attention to the following. In the enumeration of the principal crystallographic forms the author omits such commonly occurring ones as the pentagonal-dodecahedron, the icositetrahedron, the scalenohedron, and the tetrahedron, although some of these have to be referred to in subsequent pages of the work; of the *hemihedral* forms, indeed, Prof. Green makes no mention whatever. We are told that when a piece of calc-spar is broken up, "the shape of the fragments will be identically that of the block we started with." Again, we read, in reference to the subject of Polymorphism, "This is spoken of as Dimorphism, when the different *crystalline shapes* are two in number; Trimorphism when they are three in number, and so on." The italics are our own. In speaking of the constituents of a rock, the author places side by side metals and oxides in the loosest manner, and while the formula of soda is written Na_2O, that of potash stands as KO. Olivine is classed as a mineral of the augite group, and we read, "It is said that augite has never yet been found with quartz or orthoclase." "Perlite" is confounded with "sphærulite," certain rocks are spoken of as acid*ic*, trachytes are classified as *quartzless* and *quartzose*, and no mention is made of the fact that nepheline is a usual and highly important, if not an invariable, constituent of phonolites. These and many similar errors convince us that Prof. Green has hardly taken that amount of care in mastering those principles of chemistry, mineralogy, and petrology which are indispensable to the presentation of this part of his subject in a manner that will be of real service to the student. And this conclusion is confirmed when we examine the classification of rocks adopted by the author, and many of his definitions, such as those of rhyolite, hypersthene rock, and leucite-rock; or again, when we mark the want of judgment so frequently shown by him, as, for example, in rejecting the name of "porphyrite," while he retains that of "aphanite." Of the little care that has been taken to bring this part of the work "up to date," we have proofs in the circumstance that the dimorphism of silicic acid is not mentioned, and that leucite is spoken of, without hesitation, as belonging to the *cubic* system.

It is only fair, however, to point out that this very great want of accuracy is far more conspicuous in the earlier portions of the book than in its later chapters. This is a most unfortunate circumstance, inasmuch as we fear that many teachers who examine the work with a view to determine its fitness for the wants of students will be tempted to lay it down with feelings of disappointment and despair before they arrive at its really valuable portions.

We cannot but remark that Prof. Green's partial failure in a work which in many respects presents so much of promise, seems to us to have arisen from the attempt, which he boldly avows in his preface, that of making the teaching of physical geology take precedence of that of petrology and palæontology. While the petrological division of his work is treated so much more feebly, as we have already seen, than the other portions of the subject, the palæontological is omitted altogether. We do not think this can be safely done in any work on physical geology, and the danger of attempting it is well illustrated in Prof. Green's endeavour to explain the manner in which the conditions under which different deposits must have been formed is determined by geologists; in this explanation he almost entirely ignores the important evidence afforded by the characters of the animals or plants embedded in the sediments.

Rocks and fossils are the objects with which the geologist is called upon to deal at every step of his inquiries, and an accurate, if not an extensive, knowledge of them, is indispensable to the student, before he can hope to grapple successfully with those "broader questions" for which our author shows so much partiality. We cannot but regard the attempt to teach physical geology without the aid of petrology and palæontology, as bearing a suspicious resemblance to the specious promises which are made by those who profess to be able to impart a knowledge of a language without instruction in its grammar. We are sure that if such an experiment could have been successful it would have been so in the hands of so experienced a field geologist, so earnest a teacher, and so lucid a writer as Prof. Green; and, if he has to some extent failed, it is only because a more complete success, under the conditions accepted by him, was impossible. Had our author shown more deference towards the results attained by petrologists, we feel convinced that he would have written with far less boldness on such open questions as that of the "metamorphic origin of granite;" and had he admitted the importance of palæontological evidence, he would have recognised the difficulties which stand in the way of the acceptance of the theory of alternations of universal hot and cold climates during the earth's past history dependent on astronomical causes.

The views of scenery in the book are admirably selected, but unfortunately their value as illustrations of the text is greatly detracted from by the inferior style in which, in too many cases, the wood-engraving has been executed.

DITTMAR'S CHEMICAL ANALYSIS

A Manual of Qualitative Chemical Analysis. By William Dittmar, Professor of Chemistry in Anderson's University, Glasgow. (Edinburgh: Edmonston and Douglas, 1876.)

WITH the numerous works on chemical analysis already in existence we are justified in asking what special advantages Prof. Dittmar has to offer to chemical students in bringing out another book on the same subject. It will be found, in answer to this question, that the present work contrasts favourably with many of our standard books on the subject both as regards completeness, originality of treatment, and the introduction of a large amount of important matter which has not hitherto found its way into our manuals of analysis.

In giving our readers a brief sketch of Prof. Dittmar's mode of treatment, we shall point out what appear to us to be the special features in the new analysis deserving commendation.

To quote from the "Introduction":—"The book is intended for the use of students who, after they have mastered the first rudiments of chemistry, enter a laboratory to work *under the direction of a teacher*, while, at the same time, they *continue their study of theoretical chemistry.*"

Following the Introduction, we have a series of exercises calculated to make the student practically acquainted with most of the operations and processes employed in analysis. Among the readable matter interspersed between the exercises, we notice with satisfaction a clear elucidation of the meaning of the term *equivalent*—a term which appears to have dropped out of most of the modern text-books, leading students to believe (we speak from actual experience) either that the idea is altogether obsolete or is covered in some mysterious way by the word "atomicity."

We are of opinion that the meaning of "equivalent," or "equivalent weight" of an element, should be laid before all students of the science and the relationship of these numbers to the "atomic weights" clearly pointed out. In this same portion of the book will be found also an excellent exposition of the general theory of double decomposition.

The next division treats of the metals, these being divided into six groups, viz., the copper group, comprising silver, mercury, lead, copper, bismuth, cadmium (and palladium); the arsenic group, comprising this metal, antimony, tin (molybdenum, tungsten, gold, platinum, and the platinum metals other than palladium); the iron group comprising chromium, aluminium, iron (uranium), cobalt, nickel, manganese, zinc (thallium), &c.; the barium group comprising this metal, strontium, and calcium; the magnesium group consisting of this metal and lithium; and the potassium group comprising sodium, potassium (rubidium and cæsium). The method here adopted does not much differ from that in general use, excepting that the groups are considered in the same order as that followed in the systematic course of analysis instead of in the inverse order. After the reactions of each of the metals in the group have been considered, their separation from each other and from the other groups is entered upon. We are glad to see that in many cases the author does not limit himself to one particular method of separation, but gives the most effective methods known, and points out under what particular conditions each process is applicable. The reactions of the rarer metals are given in appendices to the main groups. We observe also that Bunsen's flame reactions are sometimes resorted to, this being, so far as we know, the first work since the last edition of the English translation of Fresenius' "Qualitative Analysis," in which these valuable film-tests are introduced to the notice of students in this country. This portion of the book concludes with a general scheme to be followed in performing a systematic analytical search for metals.

The third division of the work treats of the non-metallic elements. In each case the properties of the free element are first considered, then its reactions and the reactions of its acid compounds, and finally the discrimination of the element and its acid compounds in complex mixtures. The order in which the various groups are treated of is as follows:—The halogens, sulphur, selenium, and tellurium, nitrogen, phosphorus, boron, silicon, fluorine, carbon, hydrogen, and oxygen. This list of course gives no idea of the complete manner in which the author has treated the subject. That our readers may form a more just estimate of the contents of the work, we propose to point out a few selected details. Thus the chapter on the halogens includes a description of the oxygen acids of these elements and the organic halogenides; under the sulphur group we have, in addition to the reactions of the sulphides, sulphites, and sulphates, a discussion of the characters of the dithionates, polythionates, and organic sulphur compounds; under nitrogen we find ammonia, the oxides and acids, and organic nitrogen compounds (ammonium compounds are treated of as an appendix to the potassium group of metals); the acids of phosphorus are considered in great detail, and a section devoted to organic phosphorus compounds. The chapter on carbon includes the analytical characters of a large number of organic bodies, *e.g.*, cyanogen and its compounds, the fatty acids, the acids of the lactic and oxalic series; also a section on the ultimate analysis of carbon compounds. Under hydrogen the author treats of water, and under oxygen we find remarks on ozone, hydrogen peroxide, and a very complete section on the detection of this element in a combined state. This division concludes with a "Summary of operations available for the detection of the *non-metallic* constituents of substance in general, and of the *inorganic acids* in a mixture of metallic salts in particular."

Having mastered the analytical reactions of the metals and non-metals the student is, in the concluding division of the work, introduced to the analysis of substances of unknown composition. The preliminary chemical examination is conducted in the usual manner—some of the substance is first heated *per se*, then in a current of air, with "bisulphate of potash," with soda-lime, a mixture of caustic soda, nitre, &c. Then follows an account of the well-known flame and blowpipe reactions and of Bunsen's "film tests." The preliminary examination in the wet way is next undertaken, and this is followed by a section on "methods of disintegration for some of the more frequently occurring classes of substances." With regard to the exhaustive analysis of complex mixtures,

the author contents himself with a few general remarks, leaving it to the student to apply the methods acquired in working through the foregoing portions of the book, instead of guiding him, or, we should rather say, binding him down to the usual "tables."

It would be invidious on our part to institute comparisons between the present and any existing work on the same subject; but, considering the volume as the expression of the method taught by Prof. Dittmar, we are of opinion that it stands on a decidedly higher level than the generality of such works.

Although the author's accuracy is throughout unimpeachable, there are some few questionable, or at least debateable points, which demand a passing notice.

In the first place, we regret to see the occasional appearance of what we must consider badly-constructed phrases such as the following (p. 44):—"To students who have not yet got far enough advanced to invent their own methods." Then, again, we hardly know whether to admire or to condemn the frequent inconsistencies of formulation. To give a few examples:—Phosphoric acid is written in different parts of the book in no less than four different ways: thus, at p. 11, $HHHPO_4$; p. 253, $PO(OH)_3$; p. 244, $P_2O_5 . 3H_2O = 2PH_3O_4$; at pp. 244-245, the metallic phosphates are written $PO_4HR'_2$, PO_4H_2R', and $PO_4R'_3$, and on the same page metaphosphoric acid is written HPO_3. Then on the same page (41) we find two nitrates thus formulated: $HgON_2O_5$ and $Bi(NO_3)_3$. Now, although we admire the spirit which leads a writer to adopt these different modes of formulation as being a spirit of independence, which in the *original worker* shows that he is not the slave of any hypothesis, we think that the case is entirely altered when we have to deal with *students* of the science, nothing shaking the faith of a learner so much as an apparent want of consistency.

We cannot conceive why the author has gone back to the old nomenclature—"nitrate of potash," "bisulphate of potash," "phosphate of soda," &c. Although consistency is displayed throughout the book in this matter we cannot sanction the use of a system of nomenclature which, if not entirely obsolete, is rapidly becoming so among the scientific chemists in this country. Be it understood that our protest is here again entered solely from a student's point of view. It must perplex the learner to find out that the substances he has been employing in Prof. Dittmar's laboratory under the names of "bisulphate of potash," "phosphate of soda," &c., are known elsewhere as "potassic disulphate," "hydric potassic sulphate," or "hydrogen potassium sulphate," "hydric disodic phosphate," or "hydrogen disodium phosphate," &c.

With these remarks we may conclude our notice of what we venture to look upon as a valuable addition to our literature of the important subject of chemical analysis. We are confident that Prof. Dittmar's work will stand, by virtue of its own merits, as a scheme for instructing in this branch of the science.

We have in these columns (vol. xi. p. 107) formerly expressed the opinion that the systems of analysis in general use in our schools of chemistry need reforming in certain particulars. Thus in the article referred to we found occasion to complain of the want of chemical science displayed by the majority of students practising analysis according to certain cut and dried systems of "tables." It must be conceded that the student who is thoroughly well grounded in the *scientific principles* involved in chemical analysis must take a higher position than he who works blindly from a given set of rules. That some such idea is entertained by the author of the present work is shown by the fact that the three first divisions of the book are considered enough to furnish a sufficient groundwork of scientific principles to enable the use of tables to be dispensed with altogether when the analysis of complex mixtures presents itself so that both teachers and students may now congratulate themselves on possessing a work in which a step has been taken in the right direction—a system which brings into exercise the thought, knowledge, and judgment of the analyst, instead of leaving him a mere helpless machine forced to proceed in the fixed direction laid down in this or that set of "tables." R. M.

RICHARDSON'S "DISEASES OF MODERN LIFE"

Induced Diseases of Modern Life. By B. W. Richardson, M.D., M.A., F.R.S. 8vo. Pp. 520. (London: Macmillan and Co., 1876.)

HEALTH is proverbially one of the greatest blessings man can enjoy, and yet in this hardworking, hurrying, struggling age, many a one deliberately sacrifices it in the endeavour to succeed in his pursuits, commercial, literary, or scientific. Success is the object of their desires, and they are quite willing to pay for it the price of broken health and shortened life. This is even more the case with literary and scientific than with commercial men, for the latter generally look forward to several years of retirement and ease as a reward for their labours, while the former are rather anxious that their work itself shall be such as to secure them a certain place among the world's great ones, than concerned whether their fame be posthumous or not. In struggling to accomplish it they too often forget that "the race is not to the swift," but rather to the long enduring, and that if Cuvier or Darwin had died before reaching middle age, not only would their names have remained comparatively unknown, but science would have sustained an irreparable loss. Sometimes the worn-out body reminds them only too forcibly of the dependence of the mind upon it, work becomes impossible, every occupation must be renounced for a time, and the vantage ground which has been gained by unremitting toil is entirely lost. Nay more, the exhausted energies require a long time to recover; when work is resumed it can rarely be carried on with the same vigour as before, and meanwhile some slower but steadier competitor steps in front and wins the longed-for prize, or makes the eagerly-desired discovery. Several years ago we began to ascend the long flights of steps which lead to the higher part of the island of Capri, at the same time with another party. They ran briskly up while we went slowly on, and they reached the top of the first flight while we were only half way up. But here they were out of breath and stopped to rest. We, on the contrary, never stopped; if breath began to fail we went more slowly, but we never stood still. The consequence was that we passed the other party about the middle of the second flight, and

by the time they had reached its top, we had mounted the third. In such a competition as this the increasing difficulty of respiration soon warns a man to stop, but in the life-long struggle for existence it is not so easy for one to know when he is getting out of breath and to relax his exertions in time. As a help to do this Dr. Richardson's work is most valuable, for he paints in vivid colours the symptoms of disease from worry and mental strain, beginning with the slighter ones of restlessness, irritability, and "an overweening desire to do more and yet more work," and ending with dementia, diabetes, &c. He gives a most salutary warning to those who strive to counteract the effects of mental overwork by adding to it hard bodily exercise, and his remarks on physical strain should be carefully perused by all young athletes. If his cautions were constantly attended to, we would have fewer instances of break-down either mental or physical. The effects of the passions on the body are next taken up, and then the action of alcohol and tobacco discussed at length.

Dr. Richardson seems to regard alcohol as an unmitigated evil, and although he acknowledges that sometimes tobacco may be useful in soothing the excited brain, he omits this beneficial action from the summary which he gives of the effects of smoking, and includes only the baneful effects which follow the abuse of the weed. This part of his book recalls to our mind a lecture in which the late Prof. Hughes Bennett denounced pastry as one of the chief causes of consumption. No one can doubt that pastry, alcohol, and tobacco are all capable of abuse, but whether their use is to be entirely prohibited on that account is an entirely different question.

The chapters on disease from the use of narcotics, and from late hours and broken sleep are especially interesting and instructive; and that on disease from food contains some most useful remarks on the injurious effects of too much tea, coffee, soda-water, seltzer, and sweets, as well as on the consequences of over-eating.

In treating of diseases from impurity of air the author mentions the bad effects of stoves, but he might also with advantage have drawn attention to the languor and inability to work which may be induced by burning much gas in the room where one is thinking or writing. He might have mentioned the Italian proverb, that when you have built a house you should make your enemy live in it for the first year, your friend for the second, and should inhabit it yourself in the third; but his observation of the occurrence of eight cases of consumption and fourteen of rheumatic fever in one row of pretty houses during the first two years after they were built may perhaps convince people of the danger of inhabiting damp dwellings, without any additional testimony.

Other chapters deal with diseases incident to some occupations, disease from sloth and idleness, from errors of dress, from imitation and moral contagion, automatic disease and hypochondriasis, and intermarriage of disease. The book concludes with a summary of practical applications or short directions how to avoid or counteract the sources of disease already discussed.

The work is of great value as a practical guide to enable the readers to detect and avoid various sources of disease, and it contains in addition several introductory chapters on natural life and natural death, the phenomena of disease, disease antecedent to birth, and on the effects of the seasons, of atmospheric temperature, of atmospheric pressure, of moisture, winds, and atmospheric chemical changes, which are of great general interest. In several points we do not agree with Dr. Richardson; we would like him sometimes to give fuller reasons for his dogmatic statements; we think he has perhaps pictured the effects of overwork in too glaring colours, and we think he has been somewhat unfair to alcohol and tobacco. But his book is most suggestive; it is written in a most attractive style, and it may assist the work and prolong the days of some who are unwittingly destroying their health, if they will only learn and attend to its warnings and counsels.

OUR BOOK SHELF

Over the Sea and Far Away, being a Narrative of Wanderings Round the World. By Thomas Woodbine Hinchliff, M.A., F.R.G.S., President of the Alpine Club. With Fourteen Illustrations. (London: Longmans and Co., 1876.)

Mr. HINCHLIFF, who is already known as the author of one or two pleasant narratives of travel, managed, in one year, to do 36,000 miles of ocean, besides spending a considerable time in exploring various regions of America and Asia. His reasons for writing this considerable book on his tour of the world are to induce other tourists to follow his example, not in writing a book, but in leaving the beaten paths and learning something about and enjoying the many beauties of South America especially, and also because he believes there is abundant room for a further and more detailed account of the natural aspect of many of the countries visited, "especially with regard to their scenery, their flowers, ferns, and fruits." We are bound to say that Mr. Hinchliff, from these points of view, has fairly justified the publication of the present work. He writes in excellent spirits, tells clearly what he saw, keeps up the interest from beginning to end, and the general reader, at all events, will find many things in the book quite new to him. Mr. Hinchliff spent most of his time in Western North America, in California, and the Yosemité Valley especially, in Brazil, Peru, and Japan. He is a good and enthusiastic botanist, a shrewd observer, and a clear narrator. He managed to see a great deal that was well worth seeing of the countries visited, their products, and their inhabitants, and although he opened up no new ground, he has been able to suggest aspects and describe phases that, we daresay, even those familiar with the literature of travel will recognise as original. The illustrations are good and appropriate, and altogether we can recommend the work as a really interesting and instructive record of a long tour.

Une Réforme Géométrique. Introduction à la Géométrie descriptive des Cristalloïdes. Par le C^te^ Léopold Hugo. (Paris, 1874.)

Géométrie Hugodomoïdale, anhellénique, mais Philosophique et Architectonique.

La Question de l'Équidomoïde et des Cristalloïdes Géométriques. Par le C^te^ Léopold Hugo. (Paris, 1875.)

ÉQUIDOMOÏDE : Sphère : : Prisme : Cylindre. "Équidomoïde, c'est en effet le nom que j'ai proposé pour la figure polygonale qui se place *avant* la sphère, comme le prisme et la pyramide se placent avant le cylindre et le cône en vraie philosophie. Il y a donc des équidomoïdes trigonaux, tétragonaux, pentagonaux, et ainsi de suite jusqu'à ce qu'on arrive à la sphère, leur sœur cadette . . . mon nouveau système, envisageant toutes les figures polygonales qui sont les aînées de famille de tes (the extract is taken from a hypothetical address to Archimedes), sphéroïdes et conoïdes, leur donne le nom générique de *domoïdes*; puis j'y fais adjonction, comme préfixe, des

syllabes caractérisant les trois sections coniques; d'où regulièrement ellidomoïde, paradomoïde et hyperdomoïde. D'autres figures, moins chargées, au contraire, que la pyramide, sont dites *trémoïdes*. Ce seront toujours, domoïdes et trémoïdes, des corps ou solides polygonaux, ou du moins considérés comme tels, et les rapports caractéristiques $\frac{2}{3}$, $\frac{1}{2}$, se constitueront le lien commun dans chacune des diverses familles. Ce sont choses que les curieux peuvent étudier dans mon ouvrage: *Théorie des Cristalloides*."

"Geometria renovata. Création d'une géométrie nouvelle, d'une morphologie architectonique. Geometria philosophica. Doctrine préexcellente; de même que le polygone engendre le cercle, de même les cristallo-domoïdes engendrent les sphéroïdes; geometria Hugo-domoidica sive Hugodomoidalis! geometria aspheristica! de même l'équidomoïde engendre la sphère!"

"Circulaire à messieurs les mathématiciens (on est très-poli dans cette géométrique-là):—'L'équidomoïde pré-archimédien a l'honneur d'informer votre seigneurie que par arrêté de S. E. le Commandeur Léopold Hugo, Président de la Géométrique Architectoni-primordiale, il a été nommé au poste occupé précédemment par la sphère, et qu'il s'y maintiendra envers et contre tous. L'équidomoïde espère que votre seigneurie voudra bien, ainsi que LL. AA. les Académies scientifiques, accueillir favorablement sa nomination et lui donner aide et appui contre les retours offensifs de la titulaire dépossédée. Il saisit cette occasion pour exprimer à votre seigneurie toutes les assurances de sa très-respectueuse consideration.

"'Equidopolis, le .'"

The motto is "Devise anti-archimédienne. L'equidomoïde va bien: le rebelle gagne du terrain! .... suppression de la sphère!"

We have, in a recent number of NATURE, given a sketch of a work by the same author. Now we let him speak for himself. When we say that there are "Placards singuliers," "Placards plus ou moins singuliers destinés à MM. les Elèves de Mathématiques (Pamphlet fantasia)," "Objurgation Hugodomoidale," "Inauguration Transatlantique,

"Yankee doodle went to town
Upon th' equidomody,
Cocked a feather to his hat
And called it cristallody!"

&c., &c., in many languages, we have furnished our readers with some idea of the two works before us. *Spectatum admissi, risum teneatis?*

Count Hugo is the author of at least six pamphlets; two more are in the press, and more in preparation, "and still they come."

Our latest acquisition is a sheet on "the Pan-imaginary theory (not the frying-pan)." "Here the space with $\frac{l}{m}$ dimensions gives birth, by its successive phases, to the *real space*, with *n* dimensions, and specially to the *natural space* with three dimensions, and to the sub-natural space with two dimensions, &c."

LETTERS TO THE EDITOR

The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts. No notice is taken of anonymous communications.]

"The Recent Origin of Man"

THE letter of the author of the above work in NATURE, vol. xiii. p. 484, presents two points which demand an answer. 1. The reviewer is asked for his authority for the statement that palæolithic implements have been met with in Asia Minor. It is to be found in Evans' "Ancient Stone Implements," p. 571, and in Dawkins' "Cave-Hunting," p. 429. The discovery was made by the Abbé Richard between Mount Tabor and the Sea of Tiberias. 2. My opinion, which is also shared by some of the leading archæologists of Britain, that the interments at Solutré have not been proved to be palæolithic, has unfortunately evoked a charge of "ignorance and treacherous memory" from the author. I would merely remark that I am not ignorant of the account of Solutré in the "Matériaux," and in the "Archives du Muséum de Lyon," the latter of which is apparently unknown to the author, nor has my memory failed me concerning the debate on Solutré at the French Association, and the human skulls and implements which I then saw. Mr. Southall's argument as to the modern date of some of the reindeer, based on the percentage of gelatine in their bones, may be left to the tender mercies of Mr. Evans, and the comparison of the finely-chipped implements, with the Danish Neolithic finds, to those of M. de Mortillet, who takes them to be typical of one of the stages of the palæolithic period.

The discussion of the other questions raised in the letter, such as the Neolithic age of the *Rhinoceros hemitœchus* of the Gibraltar caves, or the reiterated assertion that the Irish Elk lived in Europe in the middle ages, is unnecessary in the present state of scientific inquiry. How an appeal to the mound at Hissarlik, to the discoveries at Alise, to the pile dwellings, to the food in the stomachs of fossil elephants and Mastodons, or to the recent elevation of Uddevalla can prove the "recent origin of man," may safely be reserved for decision to the judgment of the reader, without any comment from THE REVIEWER

On the Formation of Coral Sand

IN the best books on geology one finds that the formation of coral sand is attributed to trituration by the force of the surf, the waste of shells and minute globigerinæ, and even to the droppings of those fishes which are said to browse upon the living coral.

While residing at Santa Cruz in the West Indies about this time last year, my friend Mr. Quin, inspector of schools there, first pointed out to me the great importance of a certain seaweed in the formation of coral sand, and I had ample opportunity for verifying his observation while I stayed there.

A Coralline limestone is formed of coral blocks, consolidated coral-sand, and mud, shells, and myriad calcareous cases of minute organisms. Of these, next perhaps to the coral itself (of which I have seen great masses whose features were not quite effaced by percolation, &c., in the upheaved limestone of Santa Cruz), the bulkiest ingredient is the coral sand and mud, especially the sand, the shells and cases being of minor importance.

We are invariably taught, as far as I have seen, that coral sand is mainly formed of the trituration of the coral skeletons among each other, but it is difficult to see how this can be when one has seen both the sand and the skeletons, and the action of the surf which is mostly among the coral yet alive and cushioned with a vegetable matter. The coral skeleton is extremely hard and crystalline, and when two pieces of dead coral are rasped together by the action of the wave breaking over the reef they will triturate themselves into very fine grains. One can understand how the coral mud can be formed in this manner; but not so easily how the coral sand is formed. A glance at coral sand as it is seen forming the curving beaches in the pretty coves of the West Indian Islands shows that it is formed of *coarse* calcareous grains smoothed and rounded by the water, and of rather a soft friable nature, more like water-washed fragments of stucco or shell than crisp coral. On examining it more closely one sees that it is mainly composed of fragments and scales of soft calcareous matter of a mellow whiteness, and easily broken between the fingers. The larger of these scales have a peculiar shape, roughly like a half moon, whilst others are plainly only broken pieces of the larger.

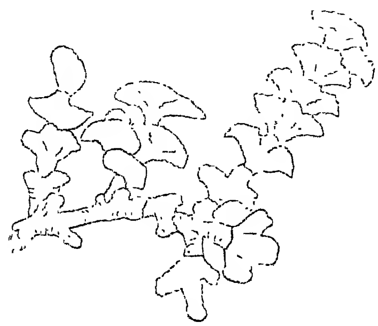
Nor is the source of these far to seek. One finds everywhere strewed over the surface of the sand white bunches of a dead sea-weed, or rather of its calcareous skeleton, bleaching in the sunshine, every perfect leaf of which is one of these half-moon shaped scales, and all connected together by flax-like fibres. They have been cast ashore by high tides from the fringing reef. (See fig.)

In the reef itself, while sailing over it, one sees among the dark coral masses white sheets of coral sand, and when these are scrutinised more closely they prove to be almost entirely formed of these broken scales or leaf-skeletons.

One day I went with Mr. Quin to the outer edge of the reef at low water, and landed on its shoaling crest. Mr. Quin was provided with a very useful lens, wherewith to view the

"wonders of the deep," in the shape of a square wooden box with a glass bottom, which on being set on the water and looked through, obviated the surface ripple, and permitted a clear view into the coral caverns, some of which, by the way, were of great beauty, natural aquarium tanks, hoary with mosses and sea-blooms, floored with coral sand and shells, and tenanted by curious fishes of the most brilliant and varied hues.

The huge rounded bosses of green growing coral among which the surf-breaks resembled much the moss-covered granite-boulders of a boggy Scotch glen. Here we found banks and beds of the coral sand where it is formed at our very hands.



The scales and half scales were here in a most perfect state, and seemed to make up almost the entire mass of sand. It was easy now to see the principal source of coral sand—at least at Santa Cruz—and that what is seen on the beach is merely what is found out here in a more finely divided state.

Over all the reef about us, growing plentifully, was the living weed which supplies these scales—the vegetable tissue covering the calcareous interior being of a dull-green like the living coral itself. I procured a specimen of the growing weed, and also of the sand from these beds where it is first formed and from the beach; but unfortunately I have lost these. I can only send you some of the dried skeleton, and append a rough sketch of it for the benefit of readers. JOHN MUNRO

Floating Radiometers

IN Mr. Crookes' paper reported in NATURE, vol. xiii. p. 489, occur the following words: "The envelope turned very slowly a few degrees in one direction, then stopped and turned a few degrees the opposite way." Assuming that this is rightly reported, it is inexplicable to me how Mr. Crookes could have written it. For, as the lawyers say, it is "void from ambiguity." The whole question between Mr. Crookes and Dr. Schuster appears to me to turn on the one point ignored by the former. When the rotation of the envelope began, in which direction was the first oscillation? To say that the envelope first turned in one direction and then in the other is simply to say that it oscillated, which, while it is a shorter mode of expressing the same thing, is an equally useless expression. The very nerve of the problem lies in the point omitted. If the first oscillation of the envelope was in the direction opposite to that of the mill, it is surely incontestable that the kick, which caused it, could not be the effect of any external force acting on the discs only.

Valentines, Ilford C. M. INGLEBY

Preece and Sivewright's "Telegraphy"

IT is neither usual nor becoming for authors to question the judgment of a reviewer in dealing with their works, and although I think that in your number (vol. xiii. p. 441) you have treated the little work by Mr. Preece and myself with some severity, I do not propose to depart from this wholesome rule. Nevertheless, I think it but right to point out that the reason why the scientific part of the subject was so far left out was because this had been already dealt with in another work of the same series. Prof. Fleeming Jenkin's text-book on "Electricity and Magnetism" had appeared before that on "Telegraphy" was undertaken. In the former "the part of science" had been so ably treated that it became unnecessary and would have been out of place to go over the same ground in a practical text-book which was to appear in the same series. J. SIVEWRIGHT

On the Nature of Musical Pipes having a Propulsive Mode of Action

IN the concluding paragraph of my last paper (NATURE, vol. xii., p. 146), I brought under notice the remarkable difference in the effect of increased diameter upon the two great classes of pipes, regarded by me as referable to the fact of the mass of air in the pipe being in the one class (that of pipes with reeds of wood or metal) under the influence of a propulsive current, and in the other class (that of pipes with reeds of air, or flue-pipes), under the influence of an abstracting current; the distinction thus manifested on the mode of action will, if clearly apprehended, enable us to reconcile many apparent anomalies in the behaviour of pipes perplexing to inquirers.

Considering a current simply as flowing, that is to say without the energy which the word propulsive implies, the nature of a tube or conduit is to cause friction between the walls of the tube and the particles of the substance flowing through the tube whether of air or of water. The friction of air upon air is also a calculable effect. In organ-pipes of the class now in question we have to recognise that we are dealing primarily with a current, with a true transport of air through a tube, a current propelled, abruptly arrested, and in a secondary stage converted into vibration; therefore all the conclusions arrived at concerning the propagation of waves of vibration in tubes are suggestively applicable here, and in practice we find these conclusions verified.

As regards ordinary tubes or conduits, Seebeck, following Regnault and Kundt, has shown (NATURE, vol. i. p. 456) that the effect of friction in retarding the velocity of a wave *in propagation* is not so insignificant as might be supposed; it is greatest upon those of tones of highest pitch, and it increases according as the diameters of the tubes are less. In musical pipes of the propulsive class exactly the same relations are preserved, and if two pipes of different diameters give the same pitch-note, then the pipe of larger diameter will prove to be of greater length, in fact the opposite of the law obtaining in pipes of the abstracting class. In a narrow pipe the friction is in excess, with an increased diameter the current gains greater freedom, and coincidently, that inner motion vibration is less impeded. Pipes of this class, for brevity here called propulsive in action, the trumpets, posaunes, bassoons, oboes, have this characteristic that the whole of the wind used passes through the body of the pipe and makes its exit at the upper orifice. In flue-pipes on the contrary the amount of wind actually passing up the interior of the pipe is scarcely noticeable. The form of trumpets and the like is conical, but the oboe has a special feature, its tube is very slender, slightly enlarging upward, until at the top it suddenly expands into a terminal shape called a bell. An actual comparison will afford the clearest illustration of the effect of form.

Two pipes of the standard pitch 256 vibrations per second:—

TRUMPET.
Sounding Mid C.

Diameter at root of reed	$\frac{3}{8}$ in.
Diameter at upper orifice...	3 "
Length from tip of reed	$23\frac{3}{8}$ "

OBOE.
Sounding Mid C.

Diameter at root of reed	$\frac{3}{16}$ in.
Diameter at upper orifice...	$\frac{3}{4}$ "
Length from tip of reed	$21\frac{1}{4}$ " (including bell)

The oboe bell is not ordinarily reckoned in the effective length, yet it is not altogether to be disregarded; from its juncture at the tube and up to the rim 3 inches, with diameter expanding from $\frac{3}{4}$ to $1\frac{1}{2}$ inches. The influence of narrow bore will be best exhibited by comparing with these the orchestral oboe where the bore commences at $\frac{3}{16}$ and the note C is given by that portion without the bell, and which will measure from the finger hole to the tip of the reed only $19\frac{1}{2}$ inches. In the Chinese organ, or "Little Shang," which, when in proper condition is most perfect in relation of tube to pitch, the pipe sounding C octave above oboe measures $9\frac{3}{8}$ in length, including the beak, and the bore of the tube is barely $\frac{1}{4}$ inch, being cylindrical, not conical. The reed tongue is so very small that a larger bore would be disproportionate, the column of air seems well suited to the strength of the reed, the pitch does not quite accord with our organ or our concert pitch, but that will not affect the argument. What I am anxious to point out is that these varying relations of pipes result from a natural standard, which underlies all empirical changes. The true standard for all instruments of the propulsive

class is *three-fourths of the half-wave length*, and then in accordance with varying diameters above stated all larger diameters demand length to be increased in ratio, and more allowance to be made for the diverging than for the uniform bore; greater or less *amount* of wind, and greater or less *degree* of pressure also enter into calculation, and practically are convertible in effect, the one doing duty for the other.

In the distinctive mode of action of this class we may find reasons for the varying relations of the pipes to each other, and for the contrasts shown in comparison with the other class acting under its own peculiar mode. In these propulsive pipes in both the wide and narrow scales, the wind-current, after entering the foot of the pipe or boot, passes into the body of the pipe by a very contracted inlet formed by a hollow plug usually of metal called "the beak," or more commonly "the reed," to the confusion of inquirers; properly named, as we see it in old authors, it is "the shallot," from its resemblance in shape to the once favourite esculent the eschallot; ordinarily we speak of "the tongue" the elastic strip of metal covering it, as "the reed," for in the clarionet this part is really a reed. The main impulse of the current passes into the cone of the pipe through the mass of air in a central direction, and thus in a wide pipe, as compared with its course in a narrow pipe, the current has exchanged the friction upon the sides for the lesser friction of air upon air, still restricted, but less so in degree as the cone expands, as of a swift river escaping the confinement of banks, flooding the quiet expanding delta, agitating its waters with gradually-decreasing strength, and then becoming diffused in surrounding ocean.

Utmost exactness in length is quite as important for pitch and tone in these as in flue-pipes. Although the reed tongue has a determinate pitch of itself, yet a proper length of tube to reciprocate its action is indispensable, any inaccuracy only "upsets the tone," as the technical phrase says, and gives rise to curious freaks of behaviour. The slim tapering oboe is so sensitive that if we make it a quarter of an inch too long, or if we merely pat the top of its bell whilst sounding, the tone will immediately leap to its third above—not to a harmonic—a problem as puzzling as that of some echoes falling successively by thirds.

The action of the air-reed as causing suction by the velocity of passage of wind over the mouth was illustrated by me in a previous paper by reference to the abstracting power of a current of air, as shown in the spray-diffuser where globules of liquid are lifted and withdrawn by its agency. The action in these beating reeds is also susceptible of as simple an illustration. Take six or eight feet of india rubber tubing of $\frac{1}{8}$-inch bore, for this length defines action more clearly—coil the length round your hand, and placing one end in the mouth blow through the tube sharply, at the same time allow the tip of your tongue freedom of play near the orifice, and you will find it drawn suddenly to the tube by the suction of the current passing down it, and released only on the exit of the current into the atmosphere. Lightly pressing the coil in your hand you may likewise feel the throb of the passing air-pulse. The trombone-player is conscious of his lip being forcibly drawn into the cup by a like cause. A stream of air suddenly cut off cannot pass down a tube without leaving a vacuum behind it. Organ and orchestral trumpets and oboes, and all of like propulsive action, are subject to this power, and only through it are able to generate tones. Suction is thus seen to be the final cause of vibration, the vacuum exists until the initial pulse of the vibration has made exit at the outer orifice, or in the second and succeeding courses until the pulses reach the colliding point or place of the prime node. Always thus in every musical pipe the current is essential to the suction, but with the striking difference that in the flue-pipe there is continuity of stream, and the continuity of flow is made available by conversion in reciprocating motion, but in the propulsive class the action is effective through discontinuity, by abrupt cessations and sequences of stream.

Here also in the beating-reed pipes we come upon distinct evidence of the interval of rest lengthening the period of vibration. The pitch of beating-reeds is regulated to consort with the pipe by means of a tuning-wire altering the vibrating length of the tongue; thus regulated, the pitch may, however, within limited degree be altered by changing the force of wind, or by cutting off rim of pipe, or by adding thereto. Let it be observed that whether the tongue is pressed to the beak slowly or quickly, it will spring back in recoil in just the same time. By additional weight of wind, pitch may be raised, and in this case the tongue flies to more rapidly, but possibly any gain of speed in the advance may be counteracted by the recoil being impeded in the more compressed medium in which the tongue moves; the only remaining effect otherwise is that of an increased swiftness of the current of air more vigorously propelled in its course, and this in itself would account for the acceleration of pitch. On the other hand, leaving the force of wind constant, we may by temporary addition to the rim of upper orifice sensibly flatten the pitch, for the current takes longer time to pass this extra boundary, hence the tongue is in consequence held longer upon the beak by the suction, its recoil delayed, or in other words recognising the physical result, its interval of rest is lengthened.

Many indications that come before me in my experiments lead directly to the inference that in all wind instruments this interval of rest is an important influence both on the pitch we regulate and in the quality we perceive; and in the estimate I shall have to give of the interior process of working in the flue organ-pipe, I shall draw upon this inference that vibration is an activity tempered by rests.

One point has been unnoticed. It would be easy to find a diapason-pipe of the same pitch showing precise agreement in length with the trumpet above specified, and similarly for other various kinds. The recognition of numerous like correspondences has led to the supposition that in relation to wave-length these two classes of pipes exhibit a parallelism. I hope to have made it clear that on the contrary, never parallel, the two classes proceed on two distinct systems of relation to wave-length, and are governed by a law, simply expressed as a law of divergent variation; they meet, it is true, but only at one point, where they cross in divergent lines, and they develop in opposite phases both in the ascending and descending extents of their range, the pitch of the one rising under an enlarging, and the other under a diminishing diameter.

Beyond the particular effects of friction already stated, the agency of the friction of air in the sound of wind instruments appears to me inadmissible. Reasons for this conclusion will occupy another paper in connection with details of my experiments bearing thereon under a simple device somewhat on the principle of the siren, and which may be named a "displacement siren." HERMANN SMITH

Solar Halo

ON Saturday last at Penruddock station, between Penrith and Keswick, about one o'clock, I observed a solar halo which at first was not perfect, but showed a reddish tint in the arc below the sun. Afterwards the circle became complete and continued so with small intervals until about half-past four, when I went indoors. At five o'clock the halo had disappeared in the haze. The day was thick, so hazy indeed that I could hardly distinguish the outline of Saddleback from Penruddock. The colour disappeared when the circle was complete, but occasionally I thought I could distinguish a reddish tinge on the inner side of the arc. I had no means of accurately measuring the radius, but with two pieces of stick which I picked up I estimated the tangent at $\frac{4}{9}$, which would give nearly 24°. This is more than your correspondent Mr. Gledhill found in his observations, but my measurement is confessedly rough. JAMES HEELIS

April 21

Safety Matches

MR. TOMLINSON'S remarks on safety-matches in NATURE, vol. xiii., p. 469, reminded me that, not long ago I accidentally kindled one of those matches by rubbing it on the edge of a Wedgwood-ware mortar. This material appears even better adapted than those mentioned by Mr. Tomlinson for igniting such matches, and I found that a common earthenware dish (glazed inside) answered the same purpose admirably. I tried to ascertain the degree of certainty with which a safety-match could be kindled by friction against these two materials, and was surprised to find that they are little inferior in this respect to amorphous phosphorus itself. After a little practice in the manner of striking, it is easy to kindle nearly every match. Thus I have lighted forty matches out of fourty-four (most of them at the first or second stroke), using the glazed portion of the basin referred to. I should add that the surface becomes improved by use, which can hardly be said of the composition on the sides of the safety-match boxes.

Manchester, April 18 FRANCIS JONES

"The Ash Seed Screw"

THE delicate twist in the samara of the ash is clearly not that best calculated to retard descent. The more decided the twist,

the greater number of revolutions will the samara perform ere reaching the ground, and the longer consequently will be the path through which its friction is exercised.

In seeking a model for a screw-propeller, we must remember that the pitch should *vary* with the velocity of propulsion.

London, April 15 WM McLAURIN

OUR ASTRONOMICAL COLUMN

THE ROTATION OF VENUS.—It was Jean Dominique Cassini (Cassini I. as he has frequently been designated) who during his residence in Italy, made the first serious attempt to ascertain the time of rotation of this planet and the position of the axis. His observations with one of Campani's long telescopes appear to have been commenced about the middle of the seventeenth century, as related in the *Journal des Savans*, 1667, Dec. 12, but it was not until the evening of Oct. 14, 1666, that he perceived any spot of sufficiently definite aspect to be of service for the purpose in view. It is described as "Une partie claire située proche de la section, et fort éloignée du centre de cette planète vers le septentrion." At the same time several dusky spots were noted. These observations were continued till June 1667, but Cassini expressed himself very cautiously with regard to the inferences to be drawn from them. They appeared to indicate a return of the bright spots to the same position upon the disc at intervals of about twenty-three hours, but from the short time that the spots could be followed Cassini was unable to decide whether the appearances were to be attributed to an axial rotation or to a libration. "De dire maintenant," he says, "supposé que ce soit toujours la même partie luisante, si ce mouvement se fait par une libration, c'est ce que je n'oserais encore assurer, parce que je n'ai pas pu voir la continuité de ce mouvement dans une grande partie de l'arc, comme dans les autres planètes, et par cette même raison cela sera toujours très-difficile à déterminer."

In 1726 Bianchini, domestic prelate of the Pope, observing at Rome, with glasses, also by Campani, of 70 to 100 Roman palms in focus, remarked on Feb. 9 several spots which he continued to observe with the view to determine the time of rotation. His observations were published in "Hesperi et Phosphori nova Phenomena," 1728, and he considered them to show a period of rotation of 24 days 8 hours, the North pole of Venus being directed to longitude 320°, with an inclination of 15° only to the plane of the ecliptic. Bianchini's observations appear to have been made under very unfavourable conditions, whereby he was prevented from following the spots in a continuous manner. They were discussed at length by Jacques Cassini, the son of Jean Dominique, in "Elemens d'Astronomie" (1740), who arrived at the conclusion that a rotation of 23 hours 20 minutes would represent equally well his father's observations and those of Bianchini, while if the rotation assigned by the latter was admitted, it would be necessary to reject entirely the observations of the elder Cassini, "comme n'etant qu'une apparence trompeuse."

Jacques Cassini mentions that after Bianchini had communicated to him the observations at Rome, he made attempts to discern the spots upon Venus at Paris. He examined the planet on a great number of occasions with a glass of 114 feet focus, one of the best produced by Hartsoëker, and also with one of Campani's, of 120 Roman palms' focus, which had been tried by Bianchini and considered excellent, but with all the precautions taken neither he nor Maraldi could perceive any distinct spot upon the planet's disc.

Schroeter, in 1789, examining Venus with a 7-feet reflector, discerned a bright spot in the dark hemisphere, and by following the appearance of this object, inferred that the planet rotated in 23h. 21m. 19s., thus supporting the result obtained by Jacques Cassini from his father's observations. Schroeter's observations appear in D. J. H. Schroeter, "Cythereographische Fragmente, oder Beobachtungen über sehr Betrachtlichen geberge und rotation der Venus," Erfurt, 1792; and in "Aphroditographische Fragmente, &c.," Helmstadt, 1796. In an appendix to the latter work, noticed by Zach in "Monatliche Correspondenz," xxv. p. 366, it is stated that observations of "atmospheric spots," and of the horns, with eight determinations of "a definite point upon the surface," give for the final value of the rotation-period of Venus, 23h. 21m. 7·98s.

De Vico's observations and investigations bearing upon the time of rotation and the position of the axis are published in "Memoria della Specola . . . in Collegio Romano," 1840–41, p. 32, and in the succeeding part of the same for 1842, p. 29. The period of rotation assigned from these observations, which were made with the Cauchoix refractor of the Roman College, is 23h. 21m. 21·93s. (sidereal time). The longitude of the ascending node of the equator of Venus upon her orbit is fixed to 56° 30′, and the inclination thereto 53° 11′, while for the same elements referred to the ecliptic we have 57° 19′ and 49° 57′. There is some error of the press or of calculation here which it is not easy to rectify. In a note to Secchi's Life of De Vico, "Memorie dell'Osservatorio . . . in Collegio Romano," Anno 1850, p. 140, the inclination of the equator of Venus to the ecliptic is given, 53° 11′ 26″, and the longitude of the ascending node of the equator upon the ecliptic for 1841, 57° 19′ 18″.

Notwithstanding the near agreement of De Vico's period of rotation with that assigned by Schroeter, it must be admitted that further investigation is very essential before we can consider the period established. There are so many negative observations upon record and these made under circumstances at least as favourable as those upon which the rotation of the planet has been supposed to be fixed, that there is ample justification for doubt in the matter.

We hear from more than one correspondent that dusky spots have been suspected upon the disc of Venus, within the last few weeks; if there be no illusion, the present may prove a favourable opportunity for attempting a new determination of the rotation-period, and this consideration has suggested the above outline of the actual state of our knowledge upon the subject.

MINOR PLANETS.—By a note from Herr Palisa it would appear that the small planet observed at Pola on November 22 and 23 was not, as supposed at the time, identical with the one he had detected on November 8. No. 155 is therefore lost or in similar predicament to the planet observed by Watson, 1873, July 29.

M. Leverrier's *Bulletin International*, of April 22, announces the discovery of another small planet at Paris, by M. Prosper Henry, during the previous night, in R.A. 14h. 9m. 58s., N.P.D., 102° 18′.

PROF. FLOWER'S HUNTERIAN LECTURES ON THE RELATION OF EXTINCT TO EXISTING MAMMALIA [1]

VIII.

THE existing families of the Carnivora, spoken of in the last lecture, do not appear to have been distinctly differentiated in the Eocene period, at all events not till towards its close, but the order was represented by other and very singular forms, the systematic position of which is not easy to determine. The earliest in point of time is *Arctocyon primævus*, from the lowest Eocene of La Fère, Aisne, France, an animal nearly as large as a wolf, with a long tail, and heavy, strong limb bones, and

[1] Abstract of a course of lectures delivered at the Royal College of Surgeons "On the Relation of Extinct to Existing Mammalia, with Special Reference to the Derivative Hypothesis," in conclusion of the course of 1873. (See Reports in NATURE for that year.) Continued from p. 488.

remarkable for the exceedingly small size of the brain cavity, compared with the arches and ridges of the skull developed for muscular attachments. This character has been supposed to indicate marsupial affinities, but the rest of the osteology, as far as known, does not favour this view. The lower jaw has not been found, but the cranium shows the full complement of teeth so frequent in Eocene mammals. There are three broad tubercular molars behind the trihedral sectorial, which indicate that the animal was rather omnivorous than truly carnivorous in its habits. Another genus which includes many species of various size, and having a wide geographical range, being found in late Eocene and early Miocene deposits in France, Germany, England, and North America, is called *Hyænodon*. It also has been by many naturalists placed among the marsupials on account of the peculiarities of its dentition, which is certainly without parallel among placental Carnivores. It possesses the primitive or typical dental formula of the Eocene mammals, and the incisors, canines, and premolars, are not unlike those of a dog, but the three true molars, both above and below, are shaped like the sectorial teeth of a cat or hyæna, and increase in size from the first to the last, and thus there are no teeth formed like the "tuberculars" of ordinary Carnivores. This repetition of the sectorial character in the true molars occurs in the carnivorous marsupials, though the general structure of the skull, and limb bones as far as they are known, including the position of the lachrymal canal within the orbit, will not permit our placing *Hyænodon* in that group. Many of the lately discovered American Eocene carnivores presented the same peculiarity of several successive molars having sectorial characters. One of these from Wyoming, apparently allied to Hyænodon, has been described by Cope, under the name of *Mesonyx*, and another still more aberrant form, as *Synoplotherium*. The inferior canines project forwards, and are closely approximated, the incisors (at all events in the aged specimen on which the genus was founded) being absent. The molar teeth were so much worn that their characters cannot be satisfactorily made out. The most interesting features of these animals are in the structure of the feet, the ungual phalanges being flatter and broader than in any existing Carnivora, and grooved above, and the scaphoid and lunar bones of the carpus not being united as in all existing Carnivores.

These naturally lead to the consideration of some animals, the remains of which have been discovered in the same locality and formation, of such anomalous construction, that they cannot be placed in any of the known groups, and for which Prof. Marsh has constituted the order *Tillodontia*. The type of the order *Tillotherium*, Marsh, is described as having a skull with the same general shape as in the bears, but in its structure resembling that of Ungulates. The molar teeth are of the Ungulate type, the canines are small, and in each jaw there is a pair of large scalpriform incisors faced with enamel, and growing from persistent pulps, as in Rodents. The adult dentition is $i\ \frac{2}{2}\ c\ \frac{1}{1}\ p\ \frac{3}{2}\ m\ \frac{3}{3}$. The articulation of the lower jaw with the skull corresponds to that in Ungulates. The brain was small and somewhat convoluted. The skeleton most resembles that of Carnivores, especially the *Ursidæ*, but the scaphoid and lunar bones are not united, and there is a third trochanter on the femur. The radius and ulna, and the tibia and fibula, are distinct. The feet are plantigrade, and each had five digits, all terminated by long, compressed and pointed ungual phalanges, somewhat similar to those in the bears. Judging from the figures and description, this animal is the same as that of which a lower jaw was previously described by Leidy as *Trogosus castoridens*, and which is perhaps identical with *Anchippodus riparius*, described by the same naturalist at a still earlier date, from a single tooth from New Jersey. If this identity can be satisfactorily established, the latter name must be adopted, but as the lower molars of so many very different animals bear a close resemblance to each other, it is not very easy to do so, and the whole history is a good illustration of the inconvenience that often arises from the practice of giving names to minute and isolated fragments.

In some of its dental and osteological characters, *Tillotherium* or *Anchippodus* bears some resemblance to the *Rodentia*, but the definition of that order would have to be widened considerably before it could be admitted within its bounds. *Mesotherium*, spoken of in the third lecture, has better claims to be considered a Rodent, though certainly a very aberrant one. Leaving this animal aside, palæontology tells us nothing of connecting, or even of more greatly generalised forms of Rodents, or affords any better indications of the affinities of the order than can be derived from the study of its living members. Nearly all the existing families have been well represented throughout the Pliocene and Miocene epochs, and the earliest known Rodents, those of the Upper Eocene, do not appear to have been more generalised than the existing species.

Numerous species of extinct *Insectivora* have been described from various formations from the Upper Eocene to the present time, both in Europe and America, but their characters and affinities have not been thoroughly worked. The European species mostly belong or are allied to genera now existing. It has been suggested that some of the generalised Amerian Eocene Carnivores may possibly be gigantic *Insectivora*, though in the actual fauna of the world there are no connecting links between these orders. It is also not certain whether some of the mammals of the Mesozoic strata may not be placental *Insectivores*.

The *Chiroptera*, or bats, differ strikingly from all other mammals in the adaptation of the fore-limbs as organs of true flight. Their origin is an extremely interesting question to the evolutionist. No existing forms throw any light upon it, and what little is known of the past history of the order shows that its general characters and geographical distribution have not changed materially during the Tertiary period. All the bats found fossil in the Brazilian caves resemble those now inhabiting the same country, though it is true these only go back as far as Pleistocene ages. In France, however, remains of bats have been found in the Miocene and Upper Eocene (Paris gypsum), but all belonging to the *Vespertilionidæ* and *Rhinolophidæ*, families now existing in Europe, and in the earliest known forms no signs of generalisation have been detected, nor have any of the intermediate stages between the ordinary mammal and the bat, if they ever existed, yet been discovered. No fossil remains of the large fruit-eating bats, or *Pteropi* have been found.

(To be continued.)

PROF. HUXLEY'S LECTURES ON THE EVIDENCE AS TO THE ORIGIN OF EXISTING VERTEBRATE ANIMALS[1]

V.

WE saw in the last lecture that the differences between birds and reptiles were very great; nevertheless, many of them tend to disappear on a closer examination. For instance, the extremely avian character of the absence of teeth, and the presence of a horny beak, is found in turtles and tortoises; that of the penetration of the bones by air cavities exists in the skull of crocodiles; and, although no existing reptile possesses the power of flight, or a fore-limb in any way approaching in structure to a bird's wing, yet, in the crocodiles, the fourth and fifth digits—those we found to be wholly absent in the bird—are much smaller than the others, and have no claws.

[1] A course of six lectures to working men, delivered in the theatre of the Royal School of Mines. Lecture V., March 27. Continued from p. 469.

On passing to the internal organs, and the mode of development, we find far greater points of resemblance; as to the latter, in fact, the correspondence is wonderful, the account given of the development of a reptile (NATURE, vol. xiii., p. 429), applying in every respect to that of a bird.

On the whole it is certain, from anatomical characters alone, that birds are modificatons of the same type as that on which reptiles are formed, and if this similarity of structure is the result of community of descent, we should expect to find, in the older formations, birds more like reptiles than any existing bird, and reptiles more like birds than any existing reptile. If the Geological record were sufficiently extensive, and the conditions of preservation favourable, we ought to find an exact series of links, but this, of course, is hardly to be expected, and it will be a great step if we can show that certain forms tend to bridge over the gulf between the two groups.

Let us see, then, what the facts of Palæontology tell us in this matter: and first, as to birds.

It is a curious fact that, just as in the case of Crocodiles, all the birds found in the Tertiary deposits differ in no essential respects from those of the present day. Great numbers of remains have been found in beds of Miocene age—beds found at the bottoms of great lakes—and the very perfectly preserved specimens show, beyond any doubt, that the Miocene birds are referable to precisely the same groups as those of our own time. Our knowledge of the Eocene forms is less perfect, but enough is known to show that the same fact held good at the commencement of the Tertiary epoch.

Throughout the secondary period remains of birds are very rare; until lately, in fact, there were none at all. But within the last ten or fifteen years some remarkable discoveries have been made—one or two in Europe, and a whole series in America, which give us some very precise information as to the nature of the Mesozoic birds.

Two of the most interesting of these—the genera *Hesperornis* and *Ichthyornis*—occur in certain beds in the United States, corresponding in age to our later Cretaceous. Hesperornis is stated, by its describer, to have had nearly the organisation of our Northern Diver (*Colymbus*); it was five or six feet in length, of swimming habits, had small wings, like those of the Penguin or Auk, and a long beak like the Diver. But—and this is the interesting feature in its organisation—both jaws were beset with teeth: not mere serrations of the jaw, such as many existing birds have, but true teeth like those of a reptile. Here then we have the appearance of a true reptilian character.

Ichthyornis was, in some respects, even more curious. It was about as large as a good-sized pigeon, had large wings adapted for powerful flight, and teeth in both jaws, like Hesperornis. In another character it showed a still greater approximation to the lower reptilian type: the bodies of its vertebræ, instead of having the cylindroidal or saddle-shaped form so characteristic of nearly all birds,[1] were bi-concave. Thus, in tracing birds back in time, we find a parallel series of modifications to those described in the Crocodilia.

Beyond this point, the history of birds is almost a blank, the only other remains being—curiously enough—one or two feathers, and the *Archæopteryx* of the Solenhofen slates, a formation which has been of great service in the preservation of organic remains, the same qualities which make it so useful for purposes of lithography having fitted it for the preservation of even such perishable structures as jelly-fish.

Archæopteryx, known only by a single specimen now in the British Museum, was a bird about the size of a crow. Its head is unfortunately wanting; its tail is quite unlike that of any existing bird, being long, composed of a great number of vertebræ, and having two rows of feathers attached, one to each side of it. The leg is quite like that of any ordinary perching bird. Unluckily, the bones of the wing are detached, so that the exact structure of the manus is not known, but it is quite certain that the metacarpal bones were not united together, but were separate and terminated by distinct claws; there was thus an approximation in structure to a true fore-paw. Long quills were attached to the wings, and both they and the tail-feathers are in an exquisite state of preservation.

With Archæopteryx we come to the end of all precise information as to the history of birds, and the only possible trace of the group in earlier formations are certain footprints found in the Trias of Connecticut, and referred to the genus *Brontozoum*. These were prints of some gigantic three-toed animal, which certainly walked on its hind legs, and was always supposed to be an ostrich-like bird until some recent discoveries, presently to be mentioned, have shown that Brontozoum may have been a reptile.

It would at first seem easy to show an equally striking approximation of reptiles to birds, for we have, throughout the greater part of the secondary rocks, and notably in the Solenhofen slates, remains of a group of reptiles known as *Pterodactyles*. These remarkable creatures had teeth set in distinct sockets, sometimes extending to the end of the long snout, sometimes stopping short, and having their place taken by a horny beak. The neck was long; the sacrum consisted of from three to six vertebræ; the tail was short in some, long in other genera. The breastbone had a great keel, like that of a bird, the shoulder-girdle was also quite birdlike, as also were the humerus and the bones of the fore-arm. The manus, on the other hand, was quite different to anything found in birds; the first, second, and third digits were of the usual reptilian character and bore claws, but the fourth was immensely prolonged, produced downwards, and clawless. The pelvis was, in some respects, birdlike, in others quite peculiar: the hind-limb was reptilian.

It is certain that the Pterodactyles were animals of flight, and that there was a membrane, like a bat's wing, stretched between the fourth finger and the sides of the body; it is also certain that it was unable to walk, though it may have used its hind-limbs, as bats do, for hanging itself head downwards from branches.

Although these creatures are, in many respects, very birdlike, yet it can hardly be said that they give us any direct help, or that they connect reptiles and birds any more than bats connect birds and mammals. Their avian characters seem to have been purely adaptive, or produced in relation to their peculiar mode of life, and we must therefore try some other line of reptiles for the origin of birds.

In the rocks from the Trias to the later Cretaceous there are, in many places, abundant remains of a group of wholly extinct terrestrial reptiles known as *Dinosauria*. Most of these are of great size, the genus *Iguanodon*, for instance, must have attained a length of fully thirty feet. Our knowledge of most of them is imperfect, but many points of the greatest possible interest are perfectly well known.

Some genera have the snout turned downwards like a turtle's beak, and both it and the large lower jaw were ensheathed in horn. In some the vertebræ are slightly excavated on both faces, and are penetrated with air cavities. The shoulder-girdle consists of a long blade-bone and a short coracoid like that of many lizards. Of the fore-limb nothing is known for certain in the larger species. The sacrum is composed of as many as six vertebræ, which often take on a remarkably birdlike character. More curious still, the ilium has a great forward process,

[1] In this peculiarly avian form of vertebra, the front face of the centrum is convex from above downwards, and concave from side to side, the hinder face being concave from above downwards, and convex from side to side. The Penguins have the dorsal vertebræ opisthocœlous, *i.e.*, with a ball in front and a cup behind.

and the ischium and pubis are both turned backwards, parallel with one another, so as to have almost exactly the same position as in birds. There can be no doubt about this most remarkable point now, as the parts have been found in place in the genus *Hypsilophodon*. The femur was evidently brought parallel to the long axis of the body, and it has the characteristic ridge between the places of articulation of the tibia and fibula. The tibia has a great crest on its front surface, the fibula is quite small, and the flattened end of the tibia fits on to a pulley-shaped bone exactly like the ankylosed astragalus of a bird. The middle or third toe is the largest, and the outer and inner toes small; the metatarsals, although separate from one another, have their faces so modelled that they must have been quite incapable of movement. Substitute ankylosis for ligamentous union, and a bird's metatarsus is produced; in fact the whole structure of the Dinosaurian hind-limb is exactly that of an embryonic bird.

In the very remarkable genus *Compsognathus* of the Solenhofen slates, which is nearly allied to the Dinosauria, and included, with them, in the order *Ornithoscelida*, the head is small, the neck extremely long, and the peculiarities of the hind-limb are entirely bird-like; it also seems that the tibia and astragalus were actually united. The fore-limb, moreover, was very small, and it is certain that Compsognathus must have walked on its hind-legs.

The question, then, naturally arises, did the gigantic Dinosauria, such as Iguandon and Megalosaurus, have the same mode of progression? This seems, at first sight, hard to believe, but there is considerable reason for thinking that it may have been the case, for, in the case mentioned above of the great three-toed footprints of the Connecticut valley and others found in the Wealden formation, no impression of a fore-foot has ever been found; so that, even if we suppose that the impressions of the fore-feet were entirely obliterated, as the animal walked, by those of the hind-feet, the former must, at any rate, have been very small.

When we consider what a very strong piece of evidence this is, we are forced to the conclusion that the evolution of birds from reptiles, by some such process as these facts indicate, is by no means such a wild speculation as it might, from *à priori* considerations, have been supposed to be.

(*To be continued.*)

THE UNEQUAL DISTRIBUTION OF RARE PLANTS IN THE ALPS[1]

M. DE CANDOLLE has recently distributed copies of a paper communicated by him to the Botanical Congress held at Florence in 1874, in which he explains in a very convincing manner a fact which all botanists have noticed in Switzerland, but the causes of which have not hitherto been properly understood. No one is better acquainted with the plants of the Alps than Mr. Ball, and M. De Candolle prints as a text to his paper a remark made by the well-known author of the Alpine Guide, that it is matter of curious inquiry to ascertain why the vegetation of certain districts of the Alps is more varied than that of others.

Two instances to illustrate this will be sufficient. The mountain chain situated between Italy and the Valais is rich in rare and local plants, while that between the Valais and Canton Bern is very poor; again, after tabulating the species found in Switzerland in single cantons only, while sixty-three are peculiar to the Valais, the Canton Bern has but one.

The explanations which have been given hitherto have mainly rested on existing physical causes. Wahlenberg, at the beginning of the century, insisted upon the action of soil and climate. Perrier and Songeon have endeavoured to correlate the distribution of plants with that of different geological formations. Grisebach, more recently, cuts the knot by supposing that the Alps have been a centre of vegetation, and that their present distribution is an ultimate fact.

De Candolle has sought the true reason in the circumstances which accompanied the retirement of the glaciers at the close of the glacial period. "The valleys and groups of mountains which have at present a maximum of rare species and the most varied flora, belong to districts in which the glaciers disappeared soonest. On the other hand, where the duration of snows and glaciers has been most prolonged, the existing flora is poor."

The objection which may be made that a cause so remote can hardly influence the present distribution, is met by pointing out the extreme slowness with which a vegetation establishes itself, and the persistence with which it maintains its *status quo* when so established. Thus the rare plants for which the botanists of the sixteenth century were accustomed to visit particular localities may still be gathered there. Again, the Rhone valley is intersected by numerous moraines; the lower and more ancient are covered with chestnuts, while the higher are more and more barren and still covered only with pines.

From a variety of causes which De Candolle enumerates, it seems probable that the southern and eastern glaciers of the Alps were of smaller extent than the northern, and would consequently be the soonest to retreat. They also probably furnished a refuge amongst their ramifications on smaller mountains which even in the Glacial period would be without snow in the summer, to some of the ancient Alpine and sub-alpine plants which were driven southwards as the glaciers increased.

We have therefore the curious fact that some of the most ancient fragments of the Alpine flora are now only to be found on the *southern* slopes of the Alps. This is the case with species of *Primula*, *Pedicularis*, and *Oxytropis*, which exist neither in the interior of Switzerland nor in the north of Europe. But it is easy to see that, like the other members of this flora, they were driven south during the Glacial period, returning as the mountains reappeared from underneath their snowy covering; while on the northern side they were in great measure exterminated. De Candolle points out as a fact in further confirmation that the Alpine species of *Campanula*, peculiar to Mont Cenis and the Simplon and neighbouring valleys, are not related to the Arctic species, but find their nearest allies in Greece, Asia Minor, and the Himalaya.

The Valais was freed from glaciers while the Mont Blanc district and the interior of Switzerland was still in the condition of Greenland. It was gradually stocked by means of species which arrived from France. The first plants to arrive must have been those which are found at the present time on the Jura and the mountains between Geneva and Chamouni. Established at first in the lower part of the valley, they would ascend as the snow diminished. The remarkable plants of the Grande Chartreuse and of Mounts Vergy and Brezon in Savoy, of the higher parts of the Western Jura, and even of the neighbourhood of Bex in Switzerland, probably belong to this period. When the perpetual snow and glaciers had disappeared from these mountains, the neighbourhood of the Lake of Geneva, the base of the Jura, and even the commencement of the Valais were more favourably circumstanced. Plants of still more southern origin could then arrive from France. This is probably the date at which the box and many *Cistineæ* and *Labiatæ*, characteristic of dry southern districts, established themselves at the foot of the Jura. Seeds carried from Italy by winds or birds introduced some of the rare

[1] Sur les Causes de l'Inégale Distribution des Plantes rares dans la Chaîne des Alpes, par Alphonse De Candolle. (Florence, 1875

species into the Lower Valais, while others of later origin were principally introduced by human agency.

During these changes the Mont Blanc district and the country between the Alps and the Jura were still ice-bound, and seeds carried by the wind from the south and west would fall on snow or sterile moraines. And when in their turn these districts were released, their opportunity of being stocked by the flora fast disappearing from the lower levels had gone. The asylums which were earliest opened were most richly supplied and have remained so.

M. De Candolle considers that a potent cause of the extermination of this flora has been the destruction of the forests which has rendered the climate south of the Alps hotter and drier in summer, and colder in winter.

The rare plants of the Italian Alps are the remains therefore of an ancient flora like that of St. Helena on its last legs. The climate of Europe tends to become drier, and M. De Candolle thinks it probable that in the course of centuries the centre of Switzerland may in turn become relatively rich in rare species, while the southern slopes of the Alps become poor. In the Lebanon and the Pyrenees this reversal of conditions has actually taken place, and their southern face—once rich probably in species re-migrating northwards—is now actually poorer than the northern. The Caucasus and the Himalaya are, however, at present comparable with the Alps. T. D.

DEEP-SEA TELEGRAPH CABLES: HOW THEY ARE TESTED

THE "testing" of a telegraph cable, whether long or short, proceeds upon the principle that the materials offer to the electrical current a certain resistance: the testing of a cable is the measurement of this resistance. In any cable there are two kinds of these resistance measurements; one of the resistance which opposes the current in its progress along the conducting wire, the other of that which opposes its lateral dispersion. The conductor-resistance is technically termed the copper-resistance, and is extremely small compared with the other resistance. The lateral resistance to the escape of the current opposed by the insulating substance which surrounds the copper-conductor is technically termed the insulation-resistance. Where the resistance to the direct propagation of the electric current through a conducting wire is represented in units, the resistance to lateral dispersion through the insulator will be represented by hundreds, or even thousands of millions, of these units. A third property is that known as the electro-static, or inductive capacity, or simply "charge"[1] of the cable; in other words, that measured quantity of electricity which the given cable will take up in a given time. So much for the necessary explanation of technical terms.

The copper-resistance (1), the insulation-resistance (2), and the "capacity" (3) are the three points to be ascertained in the testing of a cable; and it is useful to inquire why these are the points to be ascertained.

The chief commercial requisite in any cable, and upon which depends its value to its owners, is the speed with which signals can be transmitted. Speed depends directly upon two of the foregoing points (that is upon the copper resistance and "capacity"), and indirectly upon the insulation-resistance. Popular assumption is very much given to the idea that the electrical worth of a cable increases with its insulation-resistance; as usual with popular notions this is only half-truth. That the cost of a cable follows the ratio may or may not be, but it is certain that above a definite limit the thickness of the insulating coating has no effect upon the practical working condition of the cable. It may be that minor indirect benefits arise, but with these, under the present consideration of the practical testing of a cable, we have nothing to do. A certain standard of insulation-resistance attained, there remain the two points, first, of the resistance offered by the copper wire; secondly, of the charge. Now it is collaterally to be understood that, as there can be obtained through a pipe a greater flow of liquid when the pipe offers little resistance to the flow, so through the conductor of a cable can a greater flow be obtained when the conductor has low resistance. With most of the Atlantic cables each nautical mile of the conductor has a resistance equal to that of three to four of the arbitrary units selected by the profession for comparison. There are in use two units of electrical resistance, namely, that determined by a committee of the British Association and the Siemens unit. These units are very nearly of the same value, one Siemens' mercury unit (the resistance offered by a column of pure mercury of one metre length and one square millimetre section at 0° C.) being equal to 0·9536 of an Ohm, the technical term for a British Association unit. There is, then, to be considered an electrical length as well as an absolute (or ordinary) length; the proportion that one bears to the other being known, the measures are convertible. Vague as may appear to the reader this idea of electrical resistance, when he knows that of a copper wire of given diameter or weight two lengths offer twice the resistance of one, he is as learned as the most skilled electrician who virtually knows no more.

The consideration of the electrical capacity of a cable is more difficult. While the two other points relate to mass, the question of capacity involves that of surface, and of a property of the insulating material of the cable known as its "specific inductive capacity." The material with which long telegraph cables are insulated is gutta-percha. Two different cables may be insulated with this material to precisely the same dimensions, both as regards the thickness of the insulator and the thickness of the copper wire, but the "charge" taken by these cables may be very different, and the difference will be due to difference in the specific facilities offered by the two gutta-perchas to induction. This difference between various kinds of gutta-percha is as inherent as is the difference between resistances to conduction offered by different metallic alloys, and is probably very often due to want of homogeneity of the substance. It is by judicious selection and careful manipulation that the cable manufacturer is enabled to maintain a certain standard for any particular cable in question. Capacity, however, not only varies with the insulating material, but it also varies with the amount of surface of the conductor. It is different with different thicknesses of insulating material, but in this respect, after a certain limit has been passed, the decrease in capacity is very small for very large increase in the thickness of the insulating material.

High charge is incompatible with high speed. That cable will, other conditions the same, have the greatest speed in which the charge, or the fraction of the charge to be altered at each signal, is least. Professional necessity has given rise to a unit of quantity of electricity termed a "farad," of which the "micro-farad" is the millionth part. The capacity of a telegraph-cable generally ranges from three to four-tenths of a micro-farad per nautical mile.

The object of testing a cable is, then, to ascertain whether the insulation reaches the amount specified, and whether the conductor-resistance and the charge are of the required minimum. As these tests are each applied separately to the cable, their consideration will fall under the several heads. It would clearly be impossible within the limits of this paper to describe the many methods which have from time to time been proposed and in use for the testing of telegraph cables. The first methods of testing submarine lines are undoubtedly due to Dr. Werner

[1] "Capacity" and "charge" are not equivalent terms, although they are so considered in this article to prevent confusion, by the general reader, with the ordinary meaning of the word "capacity." The capacity of a cable remains constant, while the charge varies with the battery power employed.

Siemens and Dr. C. William Siemens, who early in the history of submarine telegraphy communicated their researches on the subject to the British Association at the Oxford meeting of 1860. The principle of these early methods still remains the principle of the methods employed by Sir W. Thomson in his testing of the Direct United States Cable at Ballinskelligs Bay Station in September, 1875, and upon which he has reported to the manufacturers of the cable, Messrs. Siemens Brothers. It is the purport of this paper to describe these tests and the results obtained.

To those who may be unacquainted with the route of the Direct United States cable, it will be necessary to explain that the course taken is from Ballinskelligs Bay, on the west coast of Ireland, to Torbay, in Nova Scotia, whence it again passes to Rye Beach, in New Hampshire, America.

The construction of the cable, which was decided upon by the company acting under the advice of Dr. William Siemens, their scientific consultant, is as follows:—The cable from Ireland to Nova Scotia consists of a conductor formed of a strand of twelve copper wires weighing 400 lbs. per nautical mile. This conductor is surrounded with four coatings of gutta-percha and gutta-percha-compound weighing 360 lbs. per nautical mile, so that the total weight of the "core," as it is technically termed, is 760 lbs. per knot. It was specified that the core should have an insulation resistance per nautical mile equal to 160 millions of mercury units; tests, however, checked and taken under the direction of Mr. von Chauvin, the manager and electrician to the Company, show that no length of core was passed that did not insulate to nearly double this extent, or to 300 million units per knot, the tests being taken after twenty-four hours' immersion of the core in water at 75° F. The "core" is "served" or enveloped in jute yarn, and is then sheathed or covered with iron wires of a diameter best suited to the position of the cable. Thus for the deep-sea, 1,630 knots of the cable are sheathed with ten strands of wire and hemp, each strand consisting of a homogeneous iron wire surrounded with five strands of Manilla hemp, each strand being passed through a compound of pitch, tar, and india-rubber. Each of the iron wires has an average breaking strain of 53 tons per square inch, and is of 0·099 inch diameter. The cable termed medium cable is sheathed with fifteen wires of 0·148 inch diameter with proper sewings of yarn, while for the shore ends, where there is considered to be more friction or wear, this medium cable is again surrounded with iron sheathings of twelve strands of iron wires, each strand consisting of three iron wires of 0·230 of an inch diameter.

The cable from Nova Scotia to New Hampshire consists of a strand conductor of seven copper wires weighing 107 lbs. per knot, covered with three coatings of gutta-percha and compound weighing 150 lbs. per knot, and is also sheathed with iron wires.

The non-electrical reader who may choose to wade through detail that must be somewhat technical will perhaps find help in considering the conducting wire as representing a line of flow or force, such that if two of these lines be directed into a galvanometer or current-measurer in opposite directions, that having the greatest head or greatest force will preponderate, while no indication will be found on the instrument when the forces are equal; also that from a known force giving through a known resistance a certain instrumental measure, any unknown resistance may be reduced when its instrumental measure is ascertained.

Testing the Resistance of the Copper Conductor.—Electrical measurements upon a long submerged cable differ from measurements made in the laboratory as described in text-books in one very important particular—that of earth-currents. Earth-currents are the *bête-noir* of the electrician, who not infrequently finds them so far masters of the field that his chance of obtaining accurate measures is a poor one. Fortunately, earth-currents do not have so much influence upon the working of a cable as they have upon the testing, and more fortunately still these currents do not always exist, so it is possible to obtain measures during a tranquil period. On the Direct United States' Cable, Sir William Thomson found these currents to be equal in value at a period of greatest strength to that from about eighteen cells of the testing-battery—the Irish end being positive generally to the Nova Scotian end. Under such conditions, Sir W. Thomson employed the simple deflection-method of measuring the conductor-resistance, which he takes to be "the only proper method for measuring copper-resistance in a submerged cable." In the following description of the method and its results, it will be seen that the method consists in applying together with a measuring instrument an electric force which yields a certain measure through the unknown resistance of the cable; a known resistance (7,300 units) is then substituted for the resistance of the cable, and the latter determined by proportion. The principle of this method is applicable not only to the measurement of the copper-resistance, but is that also of the ordinary method of measuring insulation-resistance, a higher known resistance being used in order more readily to effect comparison with the unknown and much greater insulation-resistance. The actual operation during the period of testing is thus described:—

"The insulation-galvanometer quickened three- or four-fold by a magnetic adjustment, and, with a shunt of twenty Siemens' units on its coil, was put in circuit between line, battery, and earth, and the deflection was observed and recorded every ten seconds. As was to be expected, large and rapid variations of the deflections were continually taking place on account of earth-currents. The direction of the earth-current was from east to west the whole time, as was shown by the 'copper' current being always greater, and the 'zinc' current less, than the true mean concluded from the observations. It increased gradually (but with some slight backward pulsation) from the beginning—when its amount was that due to a difference of potentials between the Ballinskelligs and Torbay earths equal to 1·7 of a cell—till the end, when it was more than five times as strong, and corresponded to nine cells; the Irish earth positive relatively to the Nova Scotian earth the whole time. To measure the copper-resistance a time of comparative tranquillity was chosen, a reading taken, and then as quickly as possible the galvanometer short-circuited, the battery reversed, the galvanometer circuit reopened, and a fresh reading taken. Half the space travelled by the spot of light from the first reading to the second is taken, as being the deflection which would be produced by the battery applied in either direction were there no earth-currents. This was done seven times, and the half ranges were as follows:—235, 231, 229½, 234½, 231, 235, 230—mean 232·3. I found that the same battery applied in the two directions through the galvanometer, and 7,300 Siemens' units gave 232 divisions on one side of zero, and 233 on the other—mean 232·5. Hence the copper-resistance to be inferred from the observations is—

$$7300 \times \frac{232{\cdot}5}{232{\cdot}3}, \text{ or } 7306 \text{ Siemens' units."}$$

As the cable in question is 2,420 nautical miles in length, we have $\frac{7306}{2420} = 3{\cdot}02$ Siemens' units per knot.

Insulation Test.—The ordinary method of testing the insulation-resistance of a cable consists, as has been said, in obtaining upon the galvanometer or measuring instrument a certain measure with a known resistance, and a measure with the unknown resistance, the electric force being constant during the two measurements. From these two measures the unknown resistance is determined.

If, for instance, it is known that with a certain battery power and a resistance of 100,000 units we have a deflection-measure of 100, it is deduced, when with an unknown resistance and the same battery power the deflection of 50 is obtained, that the resistance must be twice as great (namely, 200,000), since the observed effect is halved. This system is that generally pursued, but, like the other measurements upon submerged cables, comes under the effect of earth-currents; and to meet this contingency Sir William Thomson has arranged a new method, bearing upon the principle that the insulation of a cable may be determined from the proportion of loss (during a given time) of electric power that has been imparted to it. In the following description it will be seen that this loss is measured by the deflection due to the current entering the cable to make up the loss, and this deflection is compared with another deflection obtained by altering suddenly by a small quantity the battery power employed. The latter deflection being a measure of a known force or potential, the other measure for lost potential is determined, and consequently the loss of potential known.

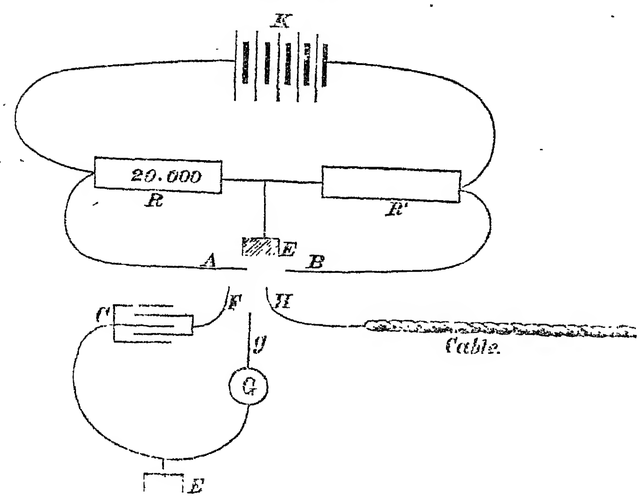
"The cable being offered to me again from midnight till 2 A.M. on the 17th, I made," says Sir W. Thomson, "another series of tests at that time for the main object of measuring the insulation-resistance. I found the line in a much less disturbed state, and was able to make a perfectly satisfactory insulation test by the ordinary galvanometer method. I applied, however, also a new method which (no electrometer being available) I had planned to meet the contingency of the line being disturbed by earth-currents so much as to render the ordinary test unsatisfactory, but not so much as to vitiate an electrometer-test. This method, which I think may be found generally useful for testing submerged cables when an electrometer is not available, is as follows:—1. Apply the ordinary test by battery and galvanometer for a certain time. 2. Insulate the cable for a certain time and then shunt the galvanometer to prepare for No. 3 (unless you have conveniently available a second galvanometer suitable for discharges). 3. Instantaneously reapply the battery, through the insulation galvanometer properly shunted (or a special discharge galvanometer), to the cable, and observe the maximum of the sudden deflection produced. 4. Go on repeating Nos. 1, 2, and 3 as long as you think proper, according to circumstances. 5. To determine the proper ballistic constant of the galvanometer for utilising the observed result of No. 3, find the maximum of the sudden deflection which takes place when a sudden change of electrification is produced by instantaneously changing by a small measured difference the potential of one electrode of the galvanometer, the other electrode being in connection with the cable. 6. The change of potential which, in the operation of No. 5, would give the same deflection as that observed in No. 3, is equal to the change of potential which the conductor of the cable has experienced during the time when it was left insulated according to No. 2. Hence calculate the insulation-resistance in ohms or megohms as in the ordinary electrometer method when the electrostatic capacity of the cable is known."

In carrying out this test, the 20-cell insulation battery (with its poles joined through 20,000 Siemens' units) was applied, zinc to cable, through the insulation galvanometer with a shunt of 5,000 Siemens' units on it. Then, the galvanometer indication was read and recorded every ten seconds for three and a half minutes, when the cable was insulated during a minute according to No. 2 of the directions above, and a shunt of 30 substituted for the 5,000. At the end of the minute the battery was instantaneously reapplied, the throw of the galvanometer observed according to No. 3 and the shunt of 30 removed, and 5,000 reapplied. The cable was again insulated for a minute, the galvanometer shunted with 50 (instead of 30 used the first time), and the operation of No. 3 repeated. The proper ballistic constant of the galvanometer was determined by applying alternately full power and $\frac{49}{50}$ of full power of the insulation battery; the change from one power to the other being made in each case as instantaneously as possible. Twelve galvanometer readings taken at ten seconds' intervals during the second and third minutes of the electrification gave for mean deflection 127, and the readings taken from the fourth to the twenty-fourth minutes gave for mean deflection 82·1. The sensibility of the galvanometer in the condition in which it was used for these readings was such that a deflection of 290 would have been given by the actual battery, with a resistance of 1,000,000 Siemens' units. Hence the insulation-resistances proved by the mean observed deflections were for the deflection, 127 from the second and third minutes 2,280,000 Siemens units, and for the mean deflection 82·1 from the fourth to twenty-fourth minutes 3,540,000 units. The new method described gave, as the mean of the observed ballistic deflections or "throws," the number 89·8, or say 90. The ballistic deflection due to instantaneously changing the potential by $\frac{1}{40}$ of that of the insulation battery, in accordance with the rule of one to five above, was found to be 112 divisions. This is $1\frac{1}{4}$ time the preceding mean throw (90), which therefore showed a change of potential equal to $\frac{1}{50}$ of that of the battery. Hence the mean fall of potential was $\frac{1}{40}$ during the minute, or at the rate of $\frac{1}{3000}$ per second. The capacity of the cable (measured in the way presently described) had been found to be 991 microfarads. Hence the insulation-resistance is $\frac{3000}{991}$, or 3·027 megohms, or 3,170,000 Siemens' units, corresponding to the 3,540,000 units given by the ordinary method. With copper to line, a fresh series of tests gave 3,520,000 megohms, or 3,690,000 Siemens' units.

In the reduction of the insulation-resistance of the whole cable to its insulation-resistance per knot, it has to be observed that as the insulation of the cable is inversely as its length, one knot of the cable will give an insulation resistance equal to that of the whole cable multiplied by the number of knots' length in the whole cable.

Measurement of "Capacity."—Just as the chemist has his vessels for measuring out quantities of liquid, so has the electrician his special arrangements for measuring out quantities of electricity; but there the analogy ends, for while the measure of the liquid is direct and visible, the electrician infers his measured quantity generally by the mechanical work effected on the index of the measuring instrument, or by the absence of such work. The apparatus used in practice for measuring quantities of electricity is termed a "condenser." "Condensers" are constructed having any required capacity, and if such a condenser of which the capacity is known is charged from a battery, then discharged through the measuring instrument, and the deflection produced noted, it is only required to charge from the same battery the cable or any other condenser of which the capacity is to be measured, then to note this discharge deflection, and by proportion to deduce the unknown capacity. On short lengths of cable this procedure is actually adopted, but on long lengths it becomes liable to error, chiefly from the fact that as with long lengths some perceptible time is required to discharge the cable, the ballistic throw or sudden deflection produced upon the measuring instrument by the rush of electricity from the cable does not measure all that passes out. It is consequently necessary to devise some method like the following used by Sir W. Thomson, in which the charge from the cable (communicated thereto by a different battery power to that charging the condenser, but the relative powers being known) is neutralised by a charge of opposite electricity from the condenser, and the neutralisation declared by the non-production of movement in the measuring instrument.

The following diagram, which is not, however, taken from the report, will explain the method :—



K, battery of 80 cells, well insulated; R resistance of 20,000 units; R', variable resistance; C, condenser of 80 microfarads' capacity; G, shunted galvanometer; E, earth.

The condenser is electrified by bringing F and A into contact, and the cable by making contact between H and B, for sufficiently long time to fully charge the cable. These contacts are then broken, and instantly after contact made between F and H. This contact is maintained for five to ten seconds, when the additional contact with *g* is made. The variable resistance is adjusted till this last contact produces no movement on the measuring instrument.

It was found that when the cable and condenser were charged to opposite potentials in the proportion of 1,615 to 20,000 no throw occurred, whence the deduction that the capacity of the cable was

$$\frac{20000}{1615} \times 80 \text{ microfarads, or}$$

991 microfarads, and the length of the cable being 2,420 knots, this was equal to 0·409 of a microfarad per knot.

In concluding the report upon the electrical conditions of the Direct United States Cable, Sir William Thomson remarks: "I am glad to be able to say that my tests proved the cable to be in perfect condition as to insulation, and showed its electrostatic capacity and copper resistance to be so small as to give it a power of transmitting messages, which, for a transatlantic cable of so great a length, is a very remarkable as well as valuable achievement." This article would be exceeding its purpose if it were to include inquiry into the present position of Atlantic Telegraphy; but it is a mark of great progress in electrical engineering and cable manufacture that a cable of such length as 2,420 miles can be delivered up to the company working it in a *perfect* electrical condition. This has not been the case in earlier transatlantic attempts; and some idea may be formed by the general reader of the care required to bring about this end, when it is known that a small hole, smaller in size than the finest pin-hole, in any portion of the two thousand miles length of gutta-percha covering would render the electrical conditions of the cable imperfect.

THE CLIMATIC CHARACTERISTICS OF WINDS AS DEPENDENT ON THEIR ORIGIN[1]

OF the climatic characteristics of winds the most important are, primarily, their temperature, and, secondarily, their moisture. The general occurrence of certain characteristics, especially when more strongly marked, with particular directions of the wind, experience soon forces on our attention, and much labour has been bestowed, particularly by Dove, in grouping the winds simply according to their directions, and calculating the mean atmospheric pressure, temperature, humidity, cloud, and rainfall, for each of the directions. Interesting and to some extent valuable results have been obtained from these inquiries; results, it must, however, be added, far from being commensurate with the enormous labour expended in arriving at them. But in extending this line of research into such regions as Western Norway, Faro, Iceland, Newfoundland, and the Azores, its unsatisfactoriness soon becomes evident; and the further consideration that the climatic qualities of a particular wind repeatedly differ widely from its general character, makes it evident that a climatic inquiry which groups the winds merely according to their direction does not proceed from a scientific basis.

A striking case, showing a great deviation from the general qualities of a wind, occurred during the great Edinburgh hurricane of the 24th of January, 1868, on which occasion the wind remained persistently in the south for several hours, and possessed a coldness and a dryness which were truly polar. The qualities of this south wind are readily explained by the limited area of high pressure, which lay immediately to the south-eastward of Scotland at the time, out of which this wind blew. As the barometer continued to fall, the wind ultimately veered to S.W. and W., and the temperature presented the unusual phenomenon of rapidly rising with a change of the wind into westward. The point to be noted here is, that as long as the wind was connected immediately with the circumscribed area of high pressure it was cold and dry, but when it was involved in the area of low pressure it became mild and moist. This relation between the climatic qualities of a wind and the state of the pressure is a vital point in atmospheric physics, and to Dr. Köppen belongs the merit of applying the principle in inaugurating a new method of inquiring into the climatic characteristics of the different winds by referring each wind-observation to the system of atmospheric pressure with which it is at the moment immediately connected.

If we examine weather-charts representing a large portion of the earth's surface, such as those published in the *Journal of the Scottish Meteorological Society*, vol. ii. p. 198, two distinct systems of pressure are seen, which change their position and form from day to day, one indicated by isobars inclosing spaces of low pressure, into which the winds all round blow vorticosely in the northern hemisphere in a direction contrary to that of the hands of a watch, and the other by isobars inclosing areas of high pressure, out of which the winds blow on all sides, but in opposite directions to those assumed in blowing inwards upon a space of low pressure. The former are usually called cyclones, and the latter anticyclones. Not only do the direction of the winds within the areas of cyclones and anticyclones respectively differ from each other, but the temperature and humidity of the winds connected with each have certain well-marked characteristics. A south-east wind at St. Petersburg, for instance, blowing in immediate connection with a cyclone, comes from the south and south-west, that is, from the southwest of Russia or from Germany; whereas a south-east wind in immediate connection with an anticyclone comes from the east, that is, either from the east of Russia or from the White Sea, and consequently these two south-east winds are markedly different in their climatic qualities from each other.

Dr. Köppen has compared the temperature, humidity, and other weather conditions at St. Petersburg each day for 1872 and 1873 with daily weather-charts constructed for the whole of Europe, and separated each of the eight winds (N., N.E., E., &c.) and calms into the following

[1] Ueber die Abhängigkeit des Klimatischen Charakters der Winde von ihrem Ursprunge. Von Dr. W. Köppen. (St. Petersburg, 1874.)

four classes:—1. Those which occur when the isobar, passing through St. Petersburg, bounds a space of low pressure, or when St. Petersburg is included within the area of a cyclone; 2. When the isobar bounds the space of high pressure, or is within the area of an anticyclone; 3. When it is in the calm centre of an anticyclone; and 4. When the isobar does not, at least on the map of Europe, inclose a space, but stretches away in a line which is either straight or irregularly waved. This division is carried out as regards the two great divisions of the year, viz., the cold half, extending from October to March, and the warm half from April to September.

The following will indicate the importance of the results arrived at:—1. *During the cold half of the year*, northerly winds (N.E. and N.) when connected with a cyclone have the pressure 0·370 inch below the average, the temperature 2°·3 above the average, the relative humidity 90, and the sky all but completely covered with cloud; with an anticyclone, pressure is 0·271 inch above the average, temperature 8°·6 below the average, humidity 84, and sky only three-fourths covered; and with a straight indeterminate isobar, pressure is 0·201 inch above the average, temperature 5°·8 below the average, humidity 89, and sky less than three-fourths covered. 2. *During the warm half of the year*, northerly winds connected with a cyclone have pressure 0·192 inch, and temperature 5°·4 below the average, humidity 87, and cloud 8; with an anticylone pressure is 0·206 inch, and temperature 0°·5 above the average, humidity 75, and cloud 4; and with straight indeterminate isobars, pressure is 0·104 inch above, and temperature 3°·4 below the average, humidity 76, and cloud 5.

As regards the S.E. wind, with a cyclone the temperature is 7°·2 above the average in winter, but only 1°·8 in summer; and with an anticyclone, 4°·0 below the average in winter, but 2°·5 above it in summer. Again, with straight isobars, S.E., S., and S.W. winds have in winter a temperature 7°·7 above the average, humidity 93, and cloud 9; but in summer the figures are 5°·2, 82, and 6 respectively. One of the most suggestive results is that obtained from the examination of the anticyclone in summer, particularly as regards its calm central space. In the periphery of the anticyclone where winds prevail, the cloud accompanying the different winds varies from 3 with S.W. to 5 with E. winds, but in the calm central space the amount is only 2; in other words, the space covered by the anticyclone is remarkable for the clearness of its sky, and the central portion is the clearest. Owing to the strong insolation which takes place under these circumstances, the temperature of the whole space covered by the anticyclone is raised 2°·1 above the average; with northerly winds (N.E., N., and N.W.) the excess is, as might be expected, small, being only 0°·5, but with S. and S.W. winds the average excess is 4°·1. The excess in the calm centre is only 1°·3, which is *smaller* than the excess which accompanies winds from the E., S.E., S., S.W., and W. points of the compass.

In a review of the weather of Europe during 1868,* Mr. Buchan drew attention to the anticyclone which overspread a considerable portion of Europe from the 2nd to 4th August, as the immediate cause of the hot weather experienced in Great Britain at the time, and which he regarded as the simple result of the widespread high pressure, the comparatively calm atmosphere, the clear sky, the dry air, and the strong insolation which accompanied these conditions. At the same time, to the west, north, and south-east, pressures were low, the sky clouded, and much rain fell. Since the wind blew out from the anticyclone in all directions,—E. and S.E. winds in Great Britain and France, W. in Austria, and S.W. in Sweden and W. in Russia,—without diminishing the high pressure of the anticyclone, it was suggested that the high pressure was maintained by air-currents ascending from the regions of low pressure to the west, north, and south-east, and thence flowing as upper currents towards and then down upon the region of the anticyclone. In connection with this point Clement Ley has made some valuable observations on the upper currents of the atmosphere, showing that they flow outwards from the centre of the cyclone, and inwards towards the anticyclone. If this view be correct, the centre of the anticyclone must necessarily be filled with a slowly descending current.

Now, it will be observed from Dr. Köppen's inquiry that the centre of the anticyclone is the clearest, on leaving which and entering the regions in which winds blow, the sky becomes more clouded—a result strictly in accordance with a descending current over the calm region of the centre. Again, in the calm centre the temperature is lower than round the periphery (except where N.E., N., and N.W. winds prevail, bringing air currents from colder regions, and therefore of a lower temperature), a result admitting of explanation only on the supposition of a descending current within the central space, since, were there no descending current, the temperature would be hottest in the centre where the atmosphere is clearest and the air stillest.

We are now, thanks to Dr. Köppen, put in possession of a truly scientific method of discussing wind-observations in their climatic relations, the value of which will be the more apparent when the observations of places in different parts of Europe have been discussed in accordance with it. What is now wanted, as regards the difficult but vital question of the observation of the wind, is that truly comparable anemometers be procurable, and that they be placed in situations and positions so that they may fairly record the direction, velocity, and pressure of the air-currents which pass over the district where they are placed.

* Atlas Météorologique de l'Observatoire Impérial, Année 1868, D. 39, Paris, 1869.

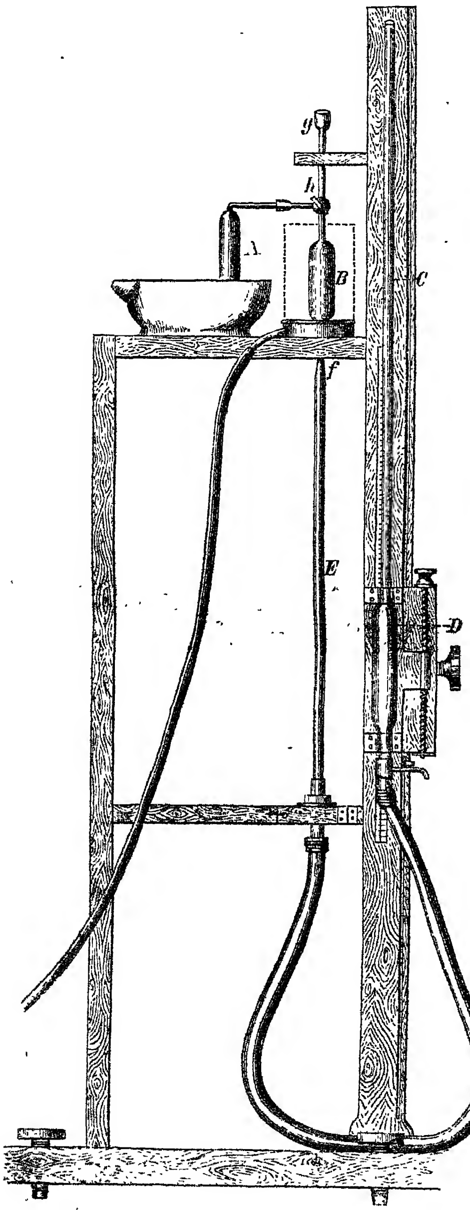
SCIENCE IN GERMANY

(*From a German Correspondent*)

M. VON JOLLY, in Munich, has recently constructed an apparatus for gas-determination by absorption. Its arrangement is, in general, similar to that of Frankland's apparatus, but it is distinguished from this, as from all other apparatus hitherto used for gas analysis, by the principle of measurement that is peculiar to it. Measurement is made, not of the changes of volume, which, for example, the air undergoes through absorption of carbonic acid and of oxygen, but of *changes of pressure, the volume remaining the same*. All the air-quantities to be measured are brought to the same volume, through corresponding change of pressure, in a measuring vessel, the contents of which must not be known; while a temperature of 0° is produced by surrounding the measuring vessel with snow or ice. Thus, each time the tension is measured under which the air-quantity to be considered assumes that constant volume, before and after absorption of a portion of the mixture. This process has various advantages over those hitherto in use. The calculation of the gas-volumes at normal pressure and temperature is rendered superfluous; the number of separate observations required is diminished.

M. Jolly's apparatus is represented in the annexed figure. A is the absorption bell-jar; it is of nearly 100 c.c. capacity. It is open below, and stands in a pneumatic trough. B is the cylindrical measuring vessel of equal capacity with the absorption jar. By means of a T-shaped perforated glass cock *h*, the vessels A and B can be connected; they can also be put in communication with the atmosphere by the capillary tube *g*. B is connected by means of a capillary tube, with a wide glass tube E. At *f* there is, within the curve, where the capillary tube opens, a small tongue of dark glass, 1 to 2 mm. long, with

the point directed downwards. (This point serves the purpose of fixing with certainty the surface of the mercury contained in E, for the point is reflected in the surface of the meniscus.) E is connected by means of caoutchouc tubing with a wide vessel D, which is fixed to a moveable carrier, and can be easily moved up and down. The tube C, which forms the vertical prolongation of the vessel D upwards, moves before a scale with millimetre divisions.



When the apparatus is to be used, a portion of D and E is first filled with mercury. Then the cock h above is opened and D pushed up to the height of the cock; whereupon the rising mercury fills the measuring vessel B, while the vessel D gets emptied. When the rising mercury comes into view in the small funnel g, you shut the cock and bring the vessel D down again, whereupon the mercury runs out of the measuring vessel and leaves there an empty space. If B be now connected with A the air is sucked over from the absorption jar into the measuring vessel, while the mercury of the pneumatic trough rises in the absorption jar. This air is also removed from the apparatus in the way above described. The air-specimen to be examined is now brought into the absorption jar, and allowed to pass over into the measuring vessel, which is surrounded with snow or pounded ice.[1] When the gas is cooled, the mercury in E is so placed that the tongue point touches the meniscus. Since the scale numbers begin at the height of the tongue point, by reading off the position of the mercury in D, the height of the mercury column is obtained, which taken together with the tension of the included air-specimen, makes equilibrium with the external air-pressure. On deducting from the immediately observed barometer height the observed column of mercury, the pressure of the enclosed air at 0° is obtained. Next, by suitable position of the vessel D and turning of the cock, the measured air-specimen is allowed to flow over again into the absortion jar. Afterwards, some small pieces of fused pyrogallic acid are introduced with a pincette under the mercury into the absorption jar. When the resulting absorption of the oxygen is finished, you measure, in the same way, in the measuring vessel, the tension of the remaining nitrogen. (The tension of the saturated water vapour at 0° = 4·6 mm. is deducted in each calculation from the tension obtained in the measuring vessel.)

Let V be the volume of the measuring vessel, P the pressure of the air-quantity contained in it, then, according to Mariotte's law—

$$V P = 760 y,$$

if y denotes the volume of this air-quantity at 0° C and 760 mm. Let P′ be the pressure of the remaining nitrogen, then—

$$V P' = 760 x,$$

where x denotes the volume of this quantity of nitrogen at 0° C and 760 mm. Consequently—

$$x = y \frac{P'}{P} = 100 \frac{P'}{P}$$

if $y = 100$.

When it is wished to analyse breathed air with this apparatus, the carbonic acid is first removed with potash lye, and the oxygen with pyrogallic acid. The oxygen may also be removed with a piece of phosphorus, by inflaming it with an induction-spark in the absorption jar.

It is known that the experiments which have been made by Maxwell, O. E. Meyer, Obermeyer, and Puluj, on the dependence of friction of gases on temperature, have not led to concordant results. M. Puluj has therefore lately made a large number of experiments with air, hydrogen, and carbonic acid, in order definitely to determine the relation between friction of gases and the temperature. This investigation was carried out in the laboratory of Prof. Kundt, in Strassburg. The apparatus used for the purpose was the friction apparatus of Kundt and Warburg, which is essentially not very different from Maxwell's, and consists of a glass disc oscillating between two fixed discs.

According to the dynamical theory of gases, the constant of friction should be proportional to the square root of the absolute temperature, *i.e.*—

$$n = n_0 (1 + \alpha \theta)^{\frac{1}{2}}$$

where n_0 denotes the constant of friction of the gas at temperature $\theta = 0°$ C., and α the coefficient of expansion of the gas. If we make, generally,

$$n = n_0 (1 + \alpha \theta)^n$$

we have from the experiments of Puluj—

For air, $n = 0·72196 \pm ·01825$ between $-3°$ C. and $+25°·6$ C.
For H, $n = 0·69312 \pm 0·01088$ „ $-1°·5$ C. and $+30°$ C.
For CO_2, $n = 0·91654 \pm 0·01394$ „ $+1°$ C. and $+29°$ C.

The exponent for air is smaller than Meyer's ($\frac{3}{4}$),

[1] To apply the ice a vertical sheet-iron cylinder is used, separable into halves; it surrounds the measuring vessel at an interval of about 3 cm. In the figure the outline of the cylinder is shown by dotted lines.

and larger than that formerly obtained by Puluj from transpiration-experiments with capillary tubes ($\frac{5}{8}$). The exponent for hydrogen is somewhat smaller than that for air. Not a little interesting is the remarkably large exponent for carbonic acid, in which the friction appears nearly to follow the law of temperature, to which Maxwell's new theory of gases leads (which, as is known, proceeds from the supposition of a repulsive action at a distance, inversely proportional to the fifth power of the distance of the molecules).

From these experiments it clearly appears that *the friction does not, in all gases, vary with the temperature in the same way.* The theory of gases must still undergo modification, in order to afford us a satisfactory explanation of this molecular process. S. W.

THE EARLY HISTORY OF MAGNETISM

THE earliest references to the properties of the magnet occur in the annals of the Chinese nation, who used it as a means of guiding the wayfarer over the vast and trackless plains of Eastern Asia, long before it was applied to maritime purposes. To the Emperor Hoang-Ti, who lived 2,000 years before our era, is attributed the invention of a chariot, upon which stood an elevated figure pointing to the south, independently of any position of the chariot. Nearly ten centuries later, we find the learned Tchéou-Koung presenting and teaching the use of the tchi-nân-kiu, or chariot indicating the south, to some envoys from Youé-tchâng, a southern maritime province. The compass, or, as it is even now called in Chinese, *tchi-nân*, appears to have been first used at sea by this remarkable nation about the third century of our era, during the Tsin dynasty.

When the compass became known in Europe is disputed; Gilbert refers its introduction to Marco Polo about 1260,[1] but it is probable that earlier accounts of it were brought from the East by the Crusaders, an accurate description of it occurring in a poem entitled "La Bible," written by the minstrel Guiot de Provence about the year 1190. A Latin letter ascribed to Peter Adsiger, 1269, preserved among the manuscripts of the university of Leyden, contains the following remark on the declination of the needle:—"Take notice that the magnet, as well as the needle that has been touched by it, does not point exactly to the poles, but that part of it which is reckoned to point to the south declines a little to the west; and that part which looks towards the north inclines as much to the east. The exact quantity of this declination I have found, after numerous experiments, to be five degrees."

The discovery of the dip of the needle is due to Robert Norman, a nautical instrument maker at Wapping, near London, who is described by Gilbert as "a skilful sailor and ingenious artificer." He found that after being touched by a magnet the needle always appeared heavier at its northern end, and making an instrument to determine the greatest angle formed with the horizon, he observed the inclination in 1576 to be 71° 50′.

In the early part of the following century, the variation of the declination was clearly ascertained, and was attributed by Bond, a teacher of navigation in London, to the motion of two magnetic poles.

In the year 1600 was published the celebrated treatise "De Magnete," by Gilbert of Colchester, who was pronounced by his great contemporary Galileo, to be "great to a degree that might be envied." Gilbert regarded our globe as a great magnet, and its centre as the centre of the magnetic motions of the earth. Variation he defines to be the arc intersected between the point where the meridian of the place cuts the horizon, and that point to which the magnetic needle looks; the length of this arc varying with the place of observation. He states that from the coast of Guinea to the Canary Islands, and thence throughout Spain, Gaul, England, Germany, and Norway, the magnetic needle turns towards the east, that on the opposite shores of North America it turns to the west, whilst near to the Azores it points exactly north and south; nor does he fail to observe that from the north of Brazil, along the coast of South America to the Straits of Magellan, the southern end of the needle points west of the true meridian. He rejects the vulgar opinions of variation depending upon magnetic mountains or magnetic rocks, upon the poles of the zodiac, or the positions of certain fixed stars, but ascribes it in some measure to the configuration of sea and land on the surface of the earth; chiefly, however, to irregularities in what he terms the magnetic globe and true earth, which he conceives to be more considerable under the continents than below the depths of the ocean. He devotes the fifth book of his work to a full account of the dip of the needle, termed by him declination, with a minute description of the instruments used in its measurement.

Descartes attributes variation to the irregularities of the earth's surface, considering magnetic attraction strongest wherever iron and loadstone are most abundant. To account for the variation of the compass, he asserts that the amount of iron in certain localities constantly changes, partly because man draws it from one place to transport it to another, and partly because new iron is formed in some districts where there was none before, whilst in others old iron becomes corrupted and disappears entirely. To explain his theory of magnetism it is necessary to state briefly the hypothesis he formed respecting matter in general, an hypothesis for which he does not claim absolute truth, but one from which deductions may be made in conformity with experience. The universe he supposed was formed originally of one uniform material, divided into equal parts having equal movements. These movements he considered to be twofold, each part revolving on its own axis, and several together revolving round fixed centres, and thus forming distinct vortices. As he deemed no void possible, it followed that these parts being equal, could not at first have been round, but might eventually become so, their angles as they met together being rubbed off and the intervening spaces filled with the dust or *débris*.

Descartes considered these two forms of matter as two elements of the universe, the first consisting of the *débris* and the second of the little spheres. The less agitated parts of the first move chiefly in straight lines from the poles to the centre of each vortex, and in passing through the triangular spaces often left between contiguous balls of the second element, they assume the form of fluted, spiral columns. On the disposition of their channels the force of the magnet principally depends. His third element is formed by the union of the less subtile matter of the first, including the fluted columns. From the centrifugal force of the round parts a central space is left within each vortex, composed purely of matter of the first element; this Descartes supposed to form an extremely subtile body, such as he conceived the fixed stars to be, and even considered that the earth formerly occupied such a centre till the less subtile matter collecting on its surface changed into that of the third element, and thus formed clouds and other obscure bodies. As each new layer was added, the force of the containing vortex diminished, and more matter escaped into the surrounding vortices than returned to occupy its place; finally, the earth, enveloped in its atmosphere, descended to the position it now occupies in the powerful vortex around the sun. He divides it into three regions, the lowest consisting entirely of matter of the first element; the middle, of an opaque solid body containing passages sufficiently large to admit the fluted columns of the first, but not the spheres of the second element,

[1] "Scientia Neuticæ pyxidulæ traducta videtur in Italiam per Paulum Venetum, qui circa annum M.CCLX. apud Chinas artem pyxidis didicet. De Magnete, p. 4.

whilst the upper is formed of a confused mass of matter which belongs chiefly to the third element, but is interspersed with the round balls of the second. The passages in the intermediate region he conceives to be so grooved that the fluted columns entering from one side cannot return again by the same passages, but when opposed in their straight course are forced back through the air or upper portions of the earth to those openings by which they entered, whilst those from the other side make similar circuits. He considers that magnets contain passages the same as those first mentioned, and such is the inclination of the fluted columns to enter these passages, that even if the poles are not turned to receive them they will push aside all opposing particles, till, if not restrained by still stronger bodies, the magnets are forced to assume those positions in which their poles point oppositely to those of the earth.[1] Such is the hypothesis of Descartes, ingenious rather than plausible, and interesting chiefly as exhibiting the speculative mind of its author.

In 1683 the celebrated Halley presented a paper of great importance to the Royal Society of London, entitled "A Theory of the Variation of the Magnetical Compass." In this communication he states that the "deflection of the magnetical needle from the true meridian is of that great concernment in the art of navigation, that the neglect thereof does little less than render useless one of the noblest inventions mankind ever yet attained to," and gives as the result of "many close thoughts" the following explanation of the variation of the compass. "The whole globe of the earth is one great magnet, having four magnetical poles or points of attraction, near each pole of the equator two; and in those parts of the world which lie near adjacent to any one of those magnetical poles, the needle is governed thereby, the nearest pole being always predominant over the more remote." He remarks that the positions of these poles cannot as yet be exactly determined from want of sufficient data, but conjectures that the magnetic pole which principally governs the variations in Europe, Tartary, and the North Sea is about 7° from the north pole of the earth, and in the meridian of the Land's End, whilst the magnetic pole which influences the needle in North America, and in the Atlantic and Pacific Oceans, from the Azores westward to Japan, is 15° from the north pole, and in a meridian passing through the middle of California. The variation in the south of Africa, in Arabia, Persia, India, and from the Cape of Good Hope, over the Indian Ocean to the middle of the South Pacific, is ruled by the most powerful of all these magnetic poles, which is situated 20° from the south pole of the earth, and in a meridian passing through the island of Celebes; in the remainder of the South Pacific Ocean, in South America and the greater part of the South Atlantic Ocean, it is governed by a magnetic pole 16° from the south pole, in a meridian 20° west of the Straits of Magellan. On this hypothesis Halley explains the variation observed in different places, and among others cites the two following instances. On the coast of America, about Virginia, New England, and Newfoundland, the variation was found to be west, being above 20° in Newfoundland, 30° in Hudson Strait, and 57° in Baffin's Bay. On the coast of Brazil, on the contrary, it was found to be east, being 12° at Cape Frio, and increasing to 20½° at the Rio de la Plata, thence decreasing towards the Straits of Magellan. Thus, almost in the same geographical meridian, we find the needle at one place pointing nearly 30° west, at another 20½° east; this is explained by the north end of the needle in Hudson Strait being chiefly attracted by the North American magnetic pole, whilst at the mouth of the Rio de la Plata the south end is attracted by the south magnetic pole, situated west of the Straits of Magellan.

[1] Descartes designates the south pole of the magnet that which turns to the north pole of the earth, and the north pole of the magnet that which turns to the south pole of the earth.

Sailing north-west from St. Helena to the equator, the variation is always in the same direction, and slightly east. Here the South American is the chief governing pole, but its power is opposed by the attraction of the North American and Asian south poles; the balance as you recede from the latter being maintained by approach to the former.

Nine years later Halley made another communication to the Royal Soceity, in which he endeavoured to meet two difficulties he had always felt in his former explanation; one, that no magnet he had ever seen or heard of had more than two opposite poles; the other, that these poles were not, at least all of them, fixed in the earth, but slowly changed their positions. The following observations are cited by Halley in proof of the motion of the magnetic system. At London, in 1580, the variation was 11° 15′, east; in 1622 it was 6° east, in 1634 it was 4° 5′ east, and in 1657 there was no variation; whilst in 1672, it was 2° 30′ west; and in 1692, 6° west. At Paris the variation was 8° or 9° east in 1550, 3° east in 1640, 0° in 1666, and 2° 30′ west in 1681. At Cape Comorin it was 14° 20′ west in 1620, 8° 48′ west in 1680, and 7° 30′ west in 1688. Halley considered the external parts of our earth as a shell, separated by a fluid medium from a nucleus or inner globe, which had its centre of gravity fixed and immovable in the common centre of the earth, but which rotated round its axis a little slower than the superficial portions of the earth. The nucleus and exterior shell he regarded as two distinct magnets, having magnetic poles not coincident with the geographical poles of the earth. The change observed in Hudson's Bay being much less than that observed in Europe, Halley concluded that the North American pole was fixed, while the European one was movable; and, from a similar observation on the coast of Java, he considered the Asian south pole as fixed, and the pole west of the Straits of Magellan to be in motion. The fixed poles he regarded as those of the external shell, and the movable those of the inner nucleus. Of these latter, the one placed by him in the meridian of the Land's End was ascertained, in the present century, to have moved to Siberia, in 120° east long., and that placed by him 20° from the Straits of Magellan to have moved between 30° and 40° west of this position; while those poles regarded by Halley as fixed were found but slightly altered in position since his time. It is extremely interesting to find that not only modern observations of declination, but also those of dip and magnetic intensity, have received their best explanation on the assumption of four magnetic poles. Much, however, that is mysterious remains unsolved, and Halley's remarkable words may even now with truth be quoted: "Whether these magnetical poles move altogether with one motion or with several; whether equally or unequally; whether circular or libratory; if circular about what centre, if libratory after what manner, are secrets as yet utterly unknown to mankind, and are reserved for the industry of future ages."

K.

THE POTATO DISEASE

IN the *Journal of the Royal Agricultural Society of England*, Second Series, vol. xii., Part I., No. xxiii., 1876, Prof. A. De Bary of the University of Strasburg has published a paper entitled "Researches into the Nature of the Potato Fungus."

De Bary's essay treats of the Peronosporeæ, Artotrogus (in its plain and echinulate forms) and Pythium. These fungi are described by De Bary as four distinct plants, whilst I, in common with several other observers, believe the first three (if indeed not all four) to be mere conditions of one and the same fungus, viz., the *Peronospora infestans* of Dr. Montagne. In replying to De Bary's remarks it will be convenient (especially as the potato-fungus appears to be somewhat imperfectly understood),

to refer to each of the above forms separately, and to illustrate each to an uniform scale. Therefore in the present paper I will confine myself to the description of the two forms of Artotrogus, and leave the consideration of Peronospora and Pythium with De Bary's criticisms of my observations for another paper.

I.—ARTOTROGUS, *Mont.*

To make my description of Artotrogus quite plain, it is necessary to briefly recapitulate the early history of the potato-fungus. Mdlle. Libert was one of the first to describe this in 1844. In the same year Mr. Berkeley writes he first saw diseased potatoes.

In 1845 Dr. Montagne described and illustrated the potato fungus. In his illustrations he included certain spherical bodies found in spent potatoes by Dr. Rayer; these bodies were attached to threads, some of the bodies being termimal (Fig. 1, A), and others within the threads

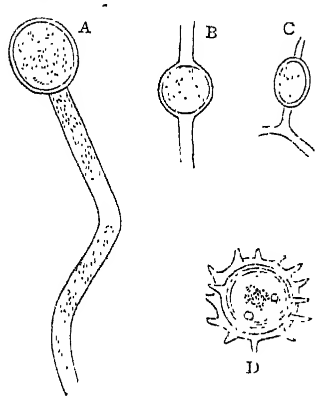


FIG. 1.—*Artotrogus hydnosporus*, Mont. A, B, C. Oogonia from Montagne's original camera-lucida drawing. D. Echinulate oogonium from De Bary ("Researches," p. 256, Fig. 3), × 400 dia.

(Fig. 1, BC), just as true oogonia are now known to occur in Cystopus and other of the Peronosporeæ. A third form (Fig. 1, D), was more or less echinulate, and this was assumed to be the mature spore. Dr. Montagne, in 1845, did not thoroughly comprehend the meaning of these bodies, so he named them provisionally Artotrogus.

From 1845 till 1875, when I rediscovered the entire series of these bodies in direct connection with *Peronospora infestans*, in the Chiswick tubers, no record of their rediscovery had ever been published. Botanists had sought for Artotrogus in vain.

In 1846, in the first vol. of the *Journal of the Royal Horticultural Society*, the Rev. M. J. Berkeley published his famous paper on the potato-murrain (the essay is dated Nov. 22, 1845), and in this paper Mr. Berkeley reproduces the description and illustration of Montagne's Artotrogus. Mr. Berkeley's published belief has for many years been that the spherical and echinulate forms of Artotrogus belong to no other than the secondary condition of the potato fungus.

In 1849, Mr. C. Edmund Broome, of Batheaston, discovered a second species of Artotrogus; this was found in decayed turnip. A copy of the original camera-lucida drawing made by Montagne is here reproduced. It shows the mycelial threads and the mature resting-spore at E.

Fourteen years afterwards (1863), Prof. A. De Bary published a paper on the development of parasitic fungi in the *Annales des Sciences Naturelles*, vol. xx. In this paper the author illustrated, amongst other things, the resting-spore of *Peronospora parasitica*, Corda, a plant common upon turnips, &c. Part of De Bary's illustration is here reproduced to show the probability of the second described species of Artotrogus being identical with the Peronospora. Some allowance must of course be made for the sketch of the turnip Artotrogus (Fig. 2), as it was made in 1849 when resting-spores were little understood, but it is clear that Mr. Broome detected

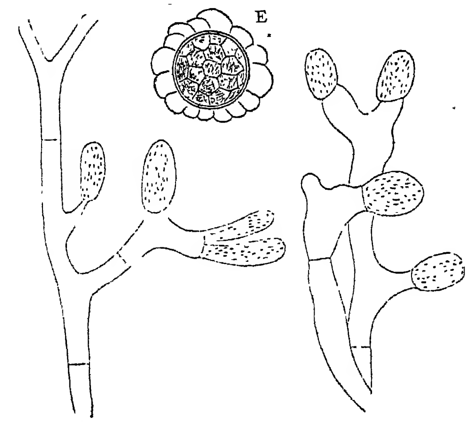

FIG. 2.—Artotrogus on decayed turnip = *Peronospora parasitica*, Corda. × 400 dia.

not only the resting-spore with its collapsed oogonium, but probably also a group of antheridia (see the detached antheridium in De Bary's illustration, Fig. 3).

This probable identity of the Artotrogus and Peronóspora of the turnip, points in the direction of the probable correctness of Mr. Berkeley's views as to the Artotrogus of the potato. The oogonia of the turnip parasite are similar in size and form with the oogonia found in potatoes, and to these latter I shall now return.

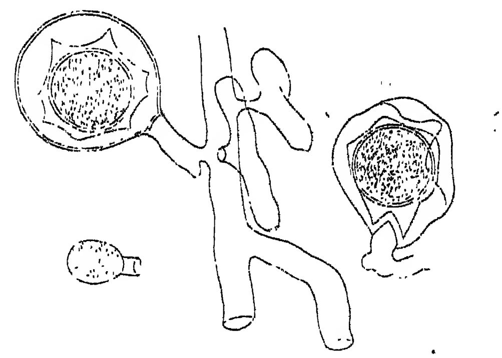

FIG. 3.—*Peronospora parasitica*, Corda. Resting-spores and detached antheridium (De Bary, "Ann. des Sc. Nat.," 4th series, vol. xx., Pl. X., Fig. 5–7), × 400 dia.

The bodies found by me in the Chiswick tubers I have from the first identified with Montagne's Artotrogus, though De Bary in his criticisms has found it convenient to omit all mention of this fact. But De Bary himself now illustrates the same bodies "from Montagne's original specimen;" this illustration is here reproduced (Fig. 4), and I can certify as to its general correctness with the reservations (1) that the oogonia shown are larger than any I have seen in the "original specimens;" (2) larger than any Montagne has figured; and (3) that De Bary has omitted all the terminal oogonia. In Montagne's original camera lucida drawing there are three terminal oogonia, one is reproduced at A (Fig. 1), with two similar bodies intercalated at B C.

De Bary (as well as Montagne, Berkeley, and myself) has also met with the more or less echinulate bodies, and one of De Bary's illustrations is reproduced, at D (Fig. 1). I agree as to its general accuracy.

Now whilst De Bary contends that all these forms are distinct species of fungi, and not belonging to the potato fungus, I maintain with Berkeley, and other competent

observers, that they are *one, including Peronospora.* I have seen them all growing from the same threads, and I will now review the grounds on which De Bary refers them to *different* fungi.

First, from De Bary's own words, I will show how extremely near the connection was, even with him. The italics are mine. He says ("Researches," p. 256), "In the tissues of potatoes *penetrated with the mycelium of Phytophthora* (De Bary's new name for the potato fungus) there sometimes appear other bodies which might be regarded as oogonia or oospores of the potato fungus. I have several times found them with Pythium vexans in old collapsed tubers which had sprouted in the ground, *and once without Pythium* in a living stalk which

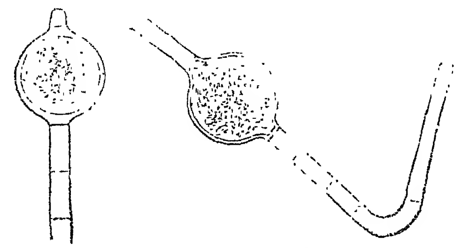

FIG. 4.—*Artotrogus hydnosporus*, Mont. De Bary's illustration ("Researches," p. 258, Fig. 8), × 400 dia.

had been on the ground. But they were *always restricted to those regions which were occupied by the Phytophthora mycelium.*" And again, "It was certainly remarkable that they were *often* situated *close* to the inner surface of the cell-walls in places where externally the mycelium of Phytophthora *undoubtedly ran in the intercellular spaces*, or even where a short branch of it *penetrated the interior of the cell.*"

In his desire, however, to dissociate these bodies from Peronospora, De Bary (p. 257) first says they were found by Montagne in a "sprouted but *not diseased potato.*" But this statement becomes of no value when De Bary himself confesses (as he does) that with him the oogonia were always restricted to those regions which "were occupied" by the *Peronospora mycelium.* I, too, have found them in similar "regions" and *upon* the *Peronospora* mycelium.

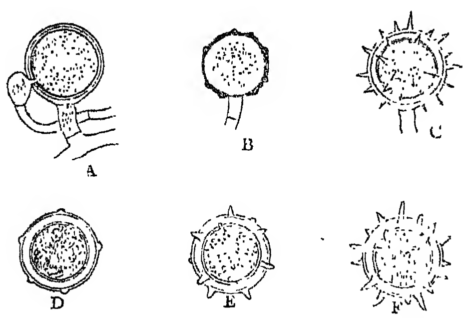

FIG. 5.—Oogonia of *Peronospora infestans*, Mont. A, B, C. Different forms from Chiswick potatoes. D. From De Bary's slide, No. IX. (common in Montagne's preparations). E. From De Bary's slide, No. XI. F. From De Bary's slide, No. X, as sent to the Royal Agricultural Society.

De Bary says (p. 256), "In most cases I found these bodies complete, mature, and without any distinct indication of their being attached to mycelium," and he says the same of Montagne's material and afterwards of mine. But this statement (like the former one) becomes of no value when we find the author writing on the very next page that after "long searching in vain he found them to grow on the extremities of the branches of a mycelium which is very like that of *Pythium vexans.*" And now what is the mycelium in *P. vexans* like? De Bary tells us, on page 253, that it is "scarcely possible to draw a positive distinction" between it and the mycelium of *Peronospora infestans!* The conclusion is obvious.

It is, perhaps, difficult to explain why a smooth oospore should become a rough or echinulate one, but the fact remains that the phenomenon is perfectly well known in fungi, notably in the spores of some of the Gasteromycetes. Plain and echinulate oospores are also produced on the same plant in some Saprolegnieæ. Max Cornu also maintains that *Saprolegnia asterophora* of De Bary is the same as the warted form of *Achlya racemosa* of Hildebrand. Dictyuchus also occurs with warted oogons. The three upper figures on the accompanying illustration (Fig. 5) are exact reproductions from different forms of oogonia found by me growing on the same threads with *Peronospora infestans.* The lower three are from De Bary's own specimens sent to the Royal Agricultural Society; D is from slide ix. (this is also very common on Montagne's preparations); E is from De Bary's slide xi., and F is from slide x. A glance at the actual preparations will show that every intermediate form is to be found.

But De Bary will not see the association, and in his concluding paragraph on Artotrogus (p. 258), he criticises Montagne and Berkeley, and says these authors "have explained the globular cells of both kinds as exhibiting progressive steps in their development, the smooth ones being the younger. For this *no reason is given,*" says De Bary, "nor have I found any in the renewed examination of the specimens. Anyone can scarcely conceive, from the known phenomena of development how the smooth

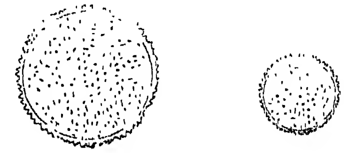

FIG. 6.—Resting-spores of *Peronospora Holostei*, Casparry. × 400 dia. From De Bary's preparation sent to the Royal Agricultural Society.

thick walled cells (the cell-walls are exactly the same in both) could become the smaller star shaped ones."

Now, the accompanying illustrations (especially Fig. 1) show De Bary to be quite wrong. The three upper oogonia on Fig. 1 are from Montagne's own camera-lucida tracing, the left-hand figure, A, is the *largest* oogonium he has shown, and the right hand oogonium, B, is the smallest. I can testify as to their correctness from an examination of the original material. The starry figure at D is one of the (presumedly) mature bodies, and is reproduced from *De Bary's own figure* ("Researches," p. 256, Fig. 3). I reproduce this figure because De Bary calls it the "common form." Now, instead of being smaller, a glance will show this echinulate body to be *larger than the largest plain oogonium found by Montagne.* On turning now to Fig. 5 it will be seen there is no "getting smaller" in the case, for all the bodies are as a rule very uniform in size, and if they vary at all they get somewhat larger instead of smaller at maturity. This is the rule, but all botanists know well that the oogonia of the Peronosporeæ are liable to vary. A good illustration of this is afforded by De Bary's own preparation of *P. Holostei*, as furnished by him to the Royal Agricultural Society. The accompanying illustration (Fig. 6) is a camera-lucida reproduction of two oogonia belonging to this species from his own slide, and it shows well how oogonia may vary in size.

Thus De Bary's notes and criticisms (taken in connection with the observations of other competent observers) on this, *the first point* (Artotrogus), completely fall to the ground. De Bary confesses to having found both forms of Artotrogus in those restricted regions *only* of diseased potatoes where *Peronospora mycelium* was *undoubtedly* and *always* present. He moreover found the bodies attached to a mycelium so like that of Peronospora

that it was almost impossible to distinguish it from Peronospora.

As regards the unfortunate criticism of Montagne and Berkeley as to the size of the oospores De Bary effectually refutes himself. WORTHINGTON G. SMITH

SCIENCE IN LEEDS

THE Annual Meeting of donors and subscribers to the Yorkshire College of Science was held in Leeds last Friday. Financially the College seems to be fairly prosperous. The subscriptions promised prior to the inauguration amounted to 28,000*l.*, and of the special fund of 10,000*l.* started by Sir Andrew Fairbairn's conditional offer of a second donation of 1,000*l.*, about 8,000*l.* have been raised. The Council are most anxious that this should be completed without delay. The College will also participate yearly in the proceeds of William Akroyd's Foundation. Of the present condition of the Yorkshire College as regards efficiency, the following communication from Mr. G. T. Bettany will afford a fair idea:—

A recent visit to Leeds enabled me to inquire into the working of the Yorkshire College of Science, which has now been in existence for nearly two years. In the building which has been temporarily adapted to the purposes of the College, I found abundant evidence of labour and study on the part of both professors and students. The attendance of seventy-five day and more than two hundred afternoon and evening students during the present session shows that the advantages offered by the College are becoming widely appreciated. Although youths are admitted at the age of fourteen, most of the students are much older; I was informed that the average age was a year and a half greater than at Owens College. The chemical department has the lion's share of accommodation; the lecture-room is large and good, and the laboratory would allow of forty students working at the same time. There have been few vacant benches during the past term. Prof. Thorpe has a room fitted up as a museum and reference library, and has also a private laboratory. A considerable amount of work is done in the department of mathematics and physics, but physical teaching suffers from want of space. Practical work can only be carried on in Prof. Rücker's private room. Geology has been fairly attended, though the day class is but small at present. Prof. Green is forming most instructive series of rock-specimens, illustrating stratigraphical geology, volcanic phenomena, and transitions in metamorphism. Mr. Miall's biological lectures have resulted in some very good work. He has prepared a large number of dissections for demonstration, including a series illustrating Prof. Rolleston's "Forms of Animal Life;" practical work has been undertaken by several students, including ladies, one of whom gained the highest place in an examination at the end of last term. Finally, the instruction on textile industries, under Mr. Beaumont, has been made scientific in many respects, especially in relation to the theory of colouring.

It can hardly be considered a misfortune that the College has been started in temporary buildings; for by means of its present effort science will become more widely appreciated, and much larger donations will come to hand than those already received; and the construction of the permanent college buildings cannot fail to be advantaged by the experience now being gained by the professors. It is to be hoped that many wealthy Yorkshire manufacturers who have at present given little or nothing to the College will be induced to follow the example of men in other localities, and liberally support a system of teaching which will be of great intellectual and material benefit to Yorkshire. I was struck with the large amount of work undertaken by the professors. When more prosperous times come, it will be for the good of the College not to exact so much work from them as their zeal is now leading them to perform.

The Leeds Philosophical Museum is becoming yet more interesting under the care of Mr. Miall, who has worthily succeeded the late Mr. Denny. The whole of the Museum is gradually being arranged in the most educative manner, and very great progress has been made. The casual visitor cannot fail to be instructed as well as interested, which can hardly be said of many more pretentious museums. Brief and clear printed descriptions or explanations abound, showing the particular interest of a specimen, or giving the general characters of a class of animals or of a geological formation. If an additional skilled curator could be appointed, who should relieve Mr. Miall from the care of several departments, the Leeds Museum would advance still more rapidly than at present, and would soon be worthy of any provincial college.

THE LATE SIR WILLIAM WILDE

SIR WILLIAM ROBERT WILLS WILDE, M.D., &c., was born in Castlerea, county of Roscommon in Ireland, in the year 1814, and he died at his residence in Dublin on the 19th instant. He was educated at the Royal School at Banagher and at the Diocesan School at Elphin; when scarcely eighteen years of age he was bound apprentice, according to the practice of those days, to the well-known surgeon, Abraham Colles, and he acquired his professional knowledge from such men as the Cramptons, Marsh, Wilmot, and Cusack. Early in 1837 he became a Licentiate of the Royal College of Surgeons in Ireland, and shortly after he resolved to devote himself to ophthalmic surgery, in which he attained a position of the highest eminence.

However distinguished as an oculist, however renowned as a writer on statistics, in these columns we lament in his decease the departure from among us of one who, as an earnest, devoted, and painstaking student of the early history of the Irish races, has left in his writings on this subject a great and an enduring monument.

Sir W. Wilde was elected a member of the Royal Irish Academy in June, 1839, having previously read two papers before the Academy, which were published in abstract in their *Proceedings*, and exhibited a collection of ancient spear-heads found in his native country. At this time the Academy had no museum (the Underwood purchase was not arranged), but in the same month that Wilde was elected, Prof. M'Cullagh munificently presented them with the Cross of Cong, "in order that he might contribute to the formation of a national collection, the want of which was regarded by Sir Walter Scott as a disgrace to a country which, like Ireland, so abounded in valuable remains." This noble gift bore speedy fruit, and meeting after meeting witnessed the presentation of donations, many of which were from time to time described by Wilde.

In 1855 Wilde was elected member of the Council of the Academy, and Secretary of Foreign Correspondence in 1857. In 1852 the Academy had moved to the premises that they at present occupy, and the Council took steps to have a catalogue of their museum made. The task was entrusted to Dr. Petrie. The resolution of the Council would seem not to have been carried into effect, and after some years of anxiety the Council and the Academy were but too happy, in March, 1857, to accept Wilde's liberal proposal to arrange and catalogue their museum. The energy that he brought to bear on this task may be judged from the fact that Part I. was ready in the month of August in the same year, when the British Association met for a second time in Dublin. Part II. was published in 1860. Part III., concluding Vol. I., in 1863. Part I. of Vol. II. had been published in the previous year. Part II. of this volume, although in great part ready, was never printed; let us add that the best

tribute of respect that the Academy could pay to Wilde's memory would be to complete this work. Few know the hours that were stolen from professional work, from the enjoyment of social life, and from much-needed rest, during the years that were engaged in this work. Despite the criticisms of some who knew little of what they criticised, this catalogue will always remain as a testimony to the author's energy and ability; already has it proclaimed far and wide what a storehouse of treasure exists under the Academy's roof. Sir William Wilde's many good qualities will keep his memory alive in the hearts of those who knew him, and when these are dead and gone it will still and for ever hover around the collection of the antiquities of the Royal Irish Academy.

MIDDLE-CLASS EDUCATION IN HOLLAND

THE following article on this subject, "from a Correspondent," appeared in the *Times* of Tuesday:—

It is not unfrequently the case that great nations search laboriously for the solution of problems which smaller peoples have completely solved, as one may say, without effort. We old-fashioned English are at present devoting much pains to discover a good system of education for our middle classes, and yet we have only to cross the Channel in order to see in actual work one altogether satisfactory in a country whose manners, traditions, and laws are almost those of our own.

According to the constitution of Holland there are three degrees of education—Primary, Middle, and Superior. As the Primary Education comprehends all schools intended for children from six to twelve years of age, and as the Universities, the Gymnasia, and other establishments where the study of the ancient languages occupies the first place, are considered as belonging to the Superior class, it follows that all educational establishments not included in one or other of these categories are regarded as establishments for middle-class education.

It appears that until the year 1862 the Dutch were no further advanced in respect of this kind of education than we are now. Wishing to put an end to this state of things, the Minister of the Interior (the Home Secretary) of the time, M. Thorbecke, formerly Professor in Leyden University, presented to Parliament a bill, which was passed into law at the beginning of the following year. From the discussions which preceded the adoption of this law, we learn that its object is to insure a suitable education to young people who are not obliged to learn a business before the age of from fourteen to seventeen years, and for whom, although they are not intended to take up University studies, a deeper and wider instruction is necessary than that which can be obtained at the primary school.

Setting out from the principle that youths who quit the primary schools may be divided into two classes —those who are able to devote only two years, and those who can afford to give five years to further study, it was decided that there should be two kinds of middle-class schools, the one to have a two years' course, and the other a course of five years.

The programme of study in the establishments in which the course is one of two years, and which are called Lower Middle-Class Schools, includes, in the first place, the elements of Mathematics, Mechanics, Physics, Chemistry, Natural History, Geography, History, and the Dutch Language, and in addition, Drawing, Gymnastics, and some idea of Political Economy and of Technology for towns, and of Agriculture for the country. The teachers in these establishments are moreover required to devote the evenings to courses for young artisans or agriculturalists who are prevented from taking the courses which are given during the day.

As to the number of these schools, the law requires that each commune whose population exceeds 10,000 shall establish at its own expense at least one Lower Middle-Class School.

The programme for those schools in which the course is one of five years, and which we may designate Upper Middle Class Schools is of course more extensive. It embraces first the branches included in the Lower Schools, but, as might be expected, this education in the Upper Schools goes much deeper. Then come three foreign languages—French, English, and German. The law requires, moreover, that the pupils should receive some notion of the political institutions of the country and of its statistics, including those of the Colonies. Needless to add, that in a country like Holland the tenure of land must form an integral part of education.

The Higher Schools are naturally those from which the most important results are to be expected, and which, from the English point of view, are best worth careful study. It is simply the truth to say that I have been amazed at what I have seen. It is a very remarkable thing that although no commune is obliged to establish a Higher School—only the State is obliged to maintain five—yet at the present time there is no town having a population of above 15,000 which has not its Higher School in full work. A still more remarkable thing is, that nowhere do the school fees exceed 5*l.* a year. As an Englishman, I was very curious to learn how they were able to give at the rate of 5*l.* a year an education which, in our happier England, can scarcely be obtained at all. This is what I learned. The expenses of a Higher School (not including the maintenance of the building) amount to about 1,750*l.* per annum. Supposing the school to be attended by 100 pupils (a medium estimate), the receipts, under the head of school fees, do not exceed 500*l.* There thus remains a deficit of 1,250*l.*; but the State generally provides a subsidy of 7,000 florins (about 583*l.*), and the town has therefore only to make up the difference by contributing 667*l.* We have supposed the school to be attended by 100 pupils, it is evident that when this number is exceeded, the receipts rise in proportion. This, however, is not always to the advantage of the Communal budget, for it should be known that in Holland a class is not allowed to contain more than thirty pupils, the result being that a greater number necessitates the creation of a double class, and this may require an increase in the number of teachers. Let us note, also, in passing, that the communes which are not able to bear the expense of a complete Higher School are authorised to establish schools of three classes corresponding to the three lower classes of a complete school.

The Communal Councils (town councils) may appoint such teachers as appear to them efficient. It is only necessary that these present certificates of competency and character, and that they have consequently passed the examinations required by the law. There are exempted from these examinations the bearers of certain academic degrees; thus for the mathematical and physical sciences the greater part of the candidates are former students of the Universities. These are generally young doctors of science who have taken a high place. Holland is not slow in showing her gratitude to them.

I have said that in the Higher Schools the school fees, although the law has not fixed a maximum, do not exceed 5*l.* For the Lower Schools the maximum is 1*l.* per annum, but this figure is rarely reached.

It is evident from the above that when a boy of twelve years of age leaves the Primary School and is not immediately obliged to earn money, his father, called in to decide whether or not he shall be sent to a Middle School, has no obstacle to face in the matter of school fees. A foreman or superior workman in a position to keep his son till he is fourteen years of age, can easily pay a shilling a month for school fees; 5*l.* would be an almost insuper-

able obstacle, though it is none to a father who is able to provide for the other wants of his son until the latter reaches the age of seventeen or eighteen years.

A Dutchman who boasted greatly of the system which his country has adopted, and to whom I remarked that it might be objected that in virtue of the system it was not himself but the taxpayers who paid for the education of his children, replied eagerly: "But am I not myself a taxpayer? Does not the system which we have adopted come simply to this, that instead of my being compelled to pay for the education of my children in a few years under the form of very heavy school-fees, the law allows me thirty or forty years in which to pay it under the form of a tax? As for myself personally, it matters very little, but look at my neighbour, whose three sons are being educated at the Higher School. Change the system; his taxes would perhaps be lessened by twenty florins, but, on the other hand, the school fees would reach so high a figure that he could not meet them. The case of my neighbour is not an exceptional one; it is the case of at least one-half of the parents who send their children to the Higher Schools. Of 100 pupils who are now attending these establishments there would remain scarcely one-half, and it would consequently be necessary to raise to 35*l.* the fees to be paid by each of them; this figure speaks more than all the arguments put together."

If in defence of a new order of things it is only necessary to urge the argument of success, it must be confessed that the advocates of the Higher Middle Schools of Holland do not require to urge any others. By universal consent the success has surpassed all expectation; it has been complete. Yet whoever knows human nature will not be astonished to find that these schools, simply because of their success, are still the object of much criticism particularly among the Clergymen and Scholars of the country. I should have wished to learn from M. Thorbecke, himself a very distinguished scholar, what he thought of these criticisms. That statesman, however, being dead, I applied to one of his former colleagues in Leyden University, whose advice M. Thorbecke to a large extent followed at the time when he was occupied in drawing up his scheme of superior education. I will give you a summary of our conversation. Having asked if it was not a mistake to found a system of education which had not Greek and Latin as its basis, he replied as follows:—

"Allow me to observe to you that our Middle Schools are not intended to produce scholars, orators, statesmen. For these there are the Gymnasium and the University. Has it moreover been thoroughly proved that the profound study of a modern foreign language cannot, as mental gymnastics, take the place of the study of a dead language? I could name to you members of our parliament who have never given any attention to Greek and Latin, and yet who, as orators, are on a par with the most eloquent of their colleagues. The Greeks are represented as having left to us in literature and in philosophy monuments of a perfection such as modern writers can never equal. Yet the Greeks studied no dead language that I know of. Besides what would it serve, in the matter of education, to make a theoretically perfect law, when the mass of the public would condemn it? If there is one idea strongly rooted in the mind of our middle classes, it is the conviction that Greek and Latin are perfectly useless to anyone who has not to pass through the University. It was daring enough to give so large a place in our new schools to the mathematical and physical sciences, to which our *bourgeoisie* had hitherto given so little attention. To go further and compel this class of people to study in addition Greek and Latin, would have been wantonly to court an inevitable defeat."

I next ventured to point out that the programme is overloaded.

"Overloaded?" replied he. "From whom have you got this accusation? From men who pass their time in their study? Speak a little with our manufacturers and our merchants, and they will give you quite another version of the matter."

"It is not said that useless subjects are taught," I went on to add; "it is urged only that too many things are taught at once, that the mind of the pupil cannot take them in, and that in the end his intellect will be enervated."

"I understand how this objection could have been urged in 1862 and 1863, during the discussion of the law, when experience had not yet pronounced; but now!—at the present time our merchants, who formerly maintained that a man of business has nothing to do with science, that it was rather an embarrassment than otherwise, now receive with open arms any young man having no other recommendation than that of having studied in one of our schools; they will tell you, moreover, that at the end of five or six weeks the new-comer is more useful to them than the majority of their old *employés*, grown gray in harness. There is more to come; it happens that some pupils of the Middle Schools, having acquired a taste for the mathematical and physical sciences, wish to complete their education at the University. Well, they almost always surpass those of their companions who come from the Gymnasia. Confess that all this is very difficult to explain if it be true that in the new schools the mind of the pupil is enervated and atrophied."

Our conversation then went on as follows:—

"You maintain then, that in your new schools, everything is for the best?"

"Pardon! I believe, on the contrary, that there is room for reform. It cannot be denied that the mediocre pupils have great difficulty in learning all that is taught them in the first three forms. Instead of three years, they would require four. The entire course ought to be six years."

"But why at the first did you not fix the course at six years?"

"Because we old-fashioned Dutch, like all the rest of the world, have our characteristic faults. We are a people essentially economical, but unfortunately we are too anxious that our children should begin early to earn money. It was a great point gained, even, to fix the course at five years. What an outcry would there have been had we taken a year more. Besides we had not then the experience that we have now."

"It will then be necessary to modify the law?"

"Yes, but gradually. There are some members of our Chambers who think it will suffice to cut out from the programme the subjects which are called superfluous. I believe it will be well not to oppose this opinion. Let us commence by setting these members to work. That which will be superfluous in the eyes of some will be quite indispensable in the estimation of others. Moreover, they cannot touch either the mathematical and physical sciences or language, and if they end by cutting out anything, a thing which appears to me very problematical, it will be of so little importance as to make scarcely any difference. It will only be when the insufficiency of all these palliatives has been well established that the time will have arrived to apply the remedy that I have indicated to you."

"You believe, then, that if we should decide in England to establish schools of a kind similar to your Higher Middle Schools, it would be necessary to have a course of six years?"

"I do not venture to assert this. You are under better conditions than we are. Our children must, beside their mother tongue, learn three foreign languages—English, French, and German; yours have only to learn French and German. This is a very important point."

"Allow me to ask you one more question. It is urged

that your Lower Middle Schools have not succeeded. To what is this ascribed?"

"It would be more correct to say that they have not succeeded throughout. Moreover, M. Thorbecke was never under any delusion on this point. He considered the Lower Middle Schools as placed for the future. The proof is that he got inserted in the law a clause which enacts that the Government may for a certain number of years exempt a communal council from the obligation of erecting a Lower Middle School if it is probable that a sufficient number of pupils could not be obtained to attend it. It is necessary first that the economical condition of the country should be improved. Remember that in Holland wages are in general lower than in all the surrounding countries. We cannot blame our poor artisans for requiring their children to earn some money at the age when these would enter the Middle School."

Such is a *résumé* of what I have seen and heard in Holland.

NOTES

AT the meeting last week of the delegates of the French Learned Societies at the Sorbonne, the Science Section was divided into three committees—Mathematical, Physico-chemical, and Natural History. The general meetings of the three sections were presided over by M. Leverrier, who developed at full length the organisation of agricultural warnings which have been established in Puy de Dome, Vienne, and Haute Vienne, and will be in operation from May 1 to October 15, when agriculturists have practically nothing to lose in the fields. About thirty stations have been established in each of these departments and connected by telegraph with the chief towns of the district. Each local observatory will receive telegraphic warnings through the préfet of the department, to whom will be sent daily the telegrams of the International Service. All these warnings will be posted at the stations and special warnings for the vicinity deduced by local meteorologists. All the observations taken on these stations will be sent to the observatory and tabulated under the supervision of M. Leverrier. The system will very likely be extended to other departments. The distribution of prizes was held on the 22nd in the large hall of the Sorbonne. The Minister of Public Instruction, M. Waddington, gave an address, in which he promised to create new libraries, new faculties, and to group new faculties in order to establish Universites. It is inferred thence that M. Waddington, who, as is well known, is a Cambridge man belonging to Trinity College, will try to remodel the French high schools according to the English method. The old Université de France is, perhaps, to be divided into the Universities of Paris, Lyons, Lille, Marseilles, and Toulouse. M. Waddington's address has created quite a sensation amongst French University men. Five gold medals were awarded—to MM. Abria (Bordeaux), for physics; Clos (Toulouse), for botany; Dumartier (Lyons), palæontology; Filhol (Toulouse), geology; Lortet (Lyons), zoology and palæontology. Ten silver medals were also awarded in botany, zoology, and natural philosophy. In connection with this meeting, M. Lecoq de Boisbandran has been made a Chevalier de la Legion d'Honneur. Several other scientific men have been appointed *officiers* of the University and *officiers* of the Paris Academy, which are special honorary degrees in acknowledgment of some special services either in the prosecution of scientific researches, or in carrying out the results of the scientific investigations of other people.

A TREASURY COMMISSION has just been appointed by Government for the purpose of inquiring into and reporting on the Queen's Colleges in Ireland. The Commissioners are the Rev. Osborne Gordon, of Christchurch, Oxford; Prof. Allman, F.R.S., M.R.I.A.; and Mr. Herbert Murray, Treasury-Remembrancer in Ireland; with Mr. B. Leech as Secretary.

SIR ROBERT CHRISTISON has resigned the position of President-elect of the forthcoming Glasgow meeting of the British Association. Dr. Andrews, of Queen's College, Belfast, has been nominated by the Council in his stead.

THE French Geographical Society are to invite Lieut. Cameron to Paris to a special meeting of the society, to be held for the purpose of marking the appreciation of his merits felt in France.

THE freedom and livery of the Turner's Company were presented at the Guildhall, on Saturday, to Lieut. Cameron and Dr. Atherstone,[1] to whose labours as a geologist the discovery of the value of the South African diamond fields is principally due.

ADMIRAL LA RONCIÈRE LE NOURRY has been reappointed by a large majority the President of the French Geographical Society.

THE French Minister of Public Instruction has given instructions for a series of observations to be made on all the streams of oceanic France, in order to determine the formation of the bar. Stations will also be established on the French coasts for observations of the tides. The previous French observations were made at Brest as far back as 1770, and on them the calculations in Laplace's "Mécanique Celeste" were based.

THE conversazione given last Friday evening at King's College by Mr. H. C. Sorby, F.R.S., to the Fellows of the Microscopical Society (of which Mr. Sorby is president) and their friends, was a brilliant and successful one. One of the greatest novelties exhibited was a new binocular spectroscope, illustrating Mr. Sorby's important discovery of a new method of measuring the position of the bands in spectra.

WE would remind our readers that the afternoon lectures at the Zoological Gardens commence to-day at 5 P.M., the first being by Mr. Sclater, F.R.S., "On the Society's Gardens and its Inhabitants." They will be continued on Thursdays for the next nine weeks.

THE first annual meeting of the Cumberland Association for the Advancement of Literature and Science, will be held at Whitehaven on May 1st and 2nd.

IN Guido Cora's *Cosmos* for April the valuable information on recent expeditions to New Guinea is continued. There is a paper by Major Wood on the Oxus in the time of Alexander, an account of Cameron's work, the continuation of G. Bove's narrative of his visit to Borneo, besides other matters of geographical interest.

PETERMANN'S *Mittheilungen* for April contains an account of the results obtained by Lieut. Cameron to accompany the excellent map of the country explored, which we have already referred to. There is an interesting account of the ascent of the two Norwegian summits, Galdhöpig and Sneehätta, by Hauptmann M. Riuth. Along with a map of New Zealand there is a long article by J. I. Kettler, showing the recent progress of that colony. Drs. Radde and Sievers furnish an interesting preliminary account of their recent travels in Caucasia and the Armenian highlands.

IN the *Bulletin* of the French Geographical Society for March, Dr. Nachtigal's account of his journey in Central Africa (1869-74) is concluded, as is also the account of Abbé David's travels in Western China in 1868-70, and M. J. Codine's paper on early Portuguese discoveries on the West African Coast. There is an itinerary from Tangier to Mogador, by M. Auguste Beaumier.

THE Physical Society of Paris held its Anniversary Meeting last Thursday.

ON Saturday, the *Times* states, there was exhibited in Wolverhampton a meteorolite weighing 8 lbs. It is believed to have fallen on Thursday afternoon in a turf field in a meadow near the Wellington and Market Drayton Railway, about a mile north of the Gradgington Station. It is stated that about ten minutes to four, within a seven miles' radius of the Wrekin, the villagers were alarmed by an unusual rumbling noise in the atmosphere, followed immediately by an explosion resembling the discharge of heavy artillery. Rain was falling heavily throughout the afternoon, but there was neither lightning nor thunder. About an hour after the report what proved to be a mass of meteoric iron was found in the meadow referred to at a depth of 18 inches, having passed through 4 inches of soil and 14 inches of clay. It rested upon the gravel underneath these. The hole is almost perpendicular, and the meteorolite is assumed to have fallen in a south-easterly direction. It is stated that the meteoric stone when found was quite hot, although nearly an hour had elapsed from the time of the explosion being heard.

THE more important articles in the *Quarterly Journal of the Meteorological Society* (London), April, 1876, are the President's Address, the Report of the Council for 1875, a paper by the Hon. Ralph Abercrombie on an improvement in aneroid barometers, and another by Colonel Puckle on Meteorology in India in relation to Cholera. The work of establishing stations begun by the Society in 1874 proceeds satisfactorily, and the Council deserve all praise for the ample details given regarding the twenty-two stations they have now established, and particularly for the valuable addition to this part of the Report, consisting in the lithographed ground-plans of the individual stations, which show the positions and surroundings of the different instruments. We regret, however, to see that the mistake in science regarding the height of the thermometers above the ground, pointed out by us (vol. xi. p. 446) still remains to be rectified, for while exact and minute directions are given respecting the various instruments, each observer is apparently left to his own discretion as to the height at which he places his thermometers. The president's remarks on lightning-rods will be read with interest; and Mr. Abercrombie's improvement on aneroids may be noticed as likely to lead to a more satisfactory observation of small barometrical fluctuations, on a correct knowledge of which so much depends.

WE have received the Programme for Easter, 1876, of the Realschule of Lippstadt. Besides a carefully arranged prospectus of the studies of the school, from the lowest to the highest class, which, in the number and nature of the subjects taught, would make most English teachers stare with wonder, there is an admirable paper by our contributor, Dr. Hermann Müller, who is a master in this school, on the system of teaching Natural History at Lippstadt.

IN a four-page monthly journal published at Laurence, Kansas, U.S., called *The Observer of Nature*, the first five numbers of vol. iii. of which have been sent us, Prof. F. H. Snow gives a catalogue of the Lepidoptera of Eastern Kansas. It is published by the Natural History Society of the Kansas State University, the Vice-President, Secretary, and Treasurer of which are ladies, and which has on its list an officer known as "Critic."

WHAT seems to have been an interesting and successful conversazione was given by the University School Naturalists' Field Club, Hastings, on Saturday week. A number of papers on subjects connected with natural history were read by the boys.

PROFESSORS JORDAN and Copeland, of Indianapolis, Indiana, U.S., are organising a scientific excursion for next summer for the benefit of those wishing to study practically the botany and zoology of the United States. They think that possibly some young Englishmen visiting the American continent during the Centennial, might wish to join such an expedition.

THE degree of LL.D. has been conferred upon Prof. Stanley Jevons, F.R.S., by the University of Edinburgh.

TO-MORROW evening, at the Royal Institution, the discourse will be given by Mr. G. J. Romanes (on the Physiology of the Nervous System of the Medusæ) instead of Prof. Gladstone, who will give the discourse on May 5th.

THE time-honoured New York Lyceum of Natural History has lately changed its title to that of the New York Academy of Sciences, and has published a circular explanatory of its object in so doing, referring to the fact of having published eleven volumes of its Annals. The circular proceeds to state that the limitation of the Society to the subject of natural history is at present unwise, and that if it desires to take a position among the first institutions of the kind at home and abroad, its scope should be greatly enlarged and its title altered to correspond. Although for many years past attention has been paid to chemistry and physics, this is not indicated in its name, and misapprehensions are likely to arise in consequence. Under the new constitution, the direction of the affairs of the Academy is placed in the hands of a body of Fellows chosen for their attainments in science, and four sections have been established, into one or the other of which all members are to be placed. These are first, zoology, botany, and microscopy; second, chemistry and technology; third, geology and mineralogy; fourth, physics, astronomy, and mathematics. Each of these has its own special administration, and is charged with the scientific work of its department. The Annals will be continued under the title of Annals of the New York Academy of Sciences, four numbers being issued every year.

A NEW ZEALAND correspondent states that he met with a curious instance of tenacity of life in the eel lately in Tasmania. Seven years ago a man placed an eel which had been slightly injured along with others in a tank from which he was in the habit of removing them for use constantly as required. The box in which they were kept was perfectly tight and fitted with finely perforated zinc at each end, through which nothing but the most minute organisms could pass. A few days afterwards, when the others were all taken out, the injured eel was left, and so again, when the next supply was put in and removed. It had got very thin, and so he left it, he said, "just to see how long it would live on nothing." It is still in the tank, perfectly transparent and quite white, and is to all appearances healthy and lively enough.

PARTS 3 and 4 of Mr. J. Clifton Ward's paper on the Granitic, Granitoid, and Associated Metamorphic Rocks of the Lake District, has been reprinted separately for the *Quarterly Journal of the Geological Society*.

A FOSSIL cockroach and earwig (*Labidura*) from South Park, Colorado, is described by Mr. S. H. Scudder in the Sixth Bulletin of the United States Geological Survey of the Territories.

A "SCHOOL of Science Philosophical Society" has been for some time established at Gloucester. The members seem bent on real work, and have already formed the nucleus of a good scientific library.

THE Fifteenth Annual Report of the Manchester Scientific Students' Association for 1875 is a very satisfactory one. It contains an account of the excursions made during the year, and also reports of several very good papers read by the members.

THE additions to the Zoological Society's Gardens during the past week include a Weeper Capuchin (*Cebus capucinus*) from Brazil, presented by Major F. J. Ricarde Seaver; a Common Otter (*Lutra vulgaris*), European, presented by Mr. J. Herbert; a Grey Squirrel (*Sciurus cinereus*) from North America, presented by Mrs. M. E. Symons; a Yarrell's Curassow (*Crax carunculata*) from South-east Brazil, presented by Mr. Aug. Ceiyoto; a Scaup Duck (*Fuligula marila*), European, presented by Mr. H. Colliver; two Common Thicknees (*Œdicnemus crepitans*), European, presented by Mr. J. E. Harting; a Coati (*Nasua nasica*) from South America, two Silky Marmosets (*Midas rosalia*) from Rio Janeiro, Brazil; five Graceful Pigeons (*Columba speciosa*) from South America, purchased; a Molucca Deer (*Cervus moluccensis*), born in the Gardens.

SCIENTIFIC SERIALS

THE current number of the *Journal of Anatomy and Physiology* commences with a paper by Dr. A. Ransome on the relative powers of fresh and previously used pepsine in the digestion of albumen, in which it is demonstrated that pepsine has greater activity after it has been used than when fresh, in which respect it is shown to agree with ptyalin, as shown by Dr. Foster, and with pancreatin according to Thiersch.—Following is a contribution on the anatomy of the cutis of the dog, by Dr. Stirling, with two plates, republished from the *Berichte d. Math. Phys. Classe der König. Sächs. Gesel. d. Wiss.*, 1875.—Mr. R. H. A. Schofield makes observations on taste-goblets in the epiglottis of the dog and cat, closely resembling the same structure in the tongue.—Dr. J. Blake, of San Francisco, describes the physiological action of the salts of beryllium, aluminium, ytrium, and cerium, by injecting them into the blood.—Dr. Brunton shows that Condurango is physiologically inert.—Mr. J. C. Ewart has a note on the abdominal pores and urogenital sinus of the lamprey, in which he demonstrates that the ureters and internal abdominal pores open into a urogenital sinus which opens behind the rectum on a papilla.—Mr. E. Thurston determines the length of the systole of the heart, as estimated from sphygmograph tracings, in which, from a series of measurements, he verifies Mr. A. H. Garrod's law that in health the systole, as indicated in the radial artery, is constant for any pulse-rate, and varies as the cube root of the rapidity.—Mr. A. M. Marshall explains the mode of oviposition of Amphioxus, verifying Kowalevsky's observation that the ova escape by the mouth.—Mr. F. Darwin describes the structure of the snail's heart histologically. No nervous mechanism was found. The contractile tissue is striated, and the fibres of the auricle and ventricle are continuous.—Dr. Stirling notes the effects of division of the sympathetic nerve in the neck of young animals.—Prof. Turner describes the structure of the non-gravid uterine mucous membrane in the kangaroo, and makes a note on the dentition of the narwhal.—Mr. F. M. Balfour continues his valuable account of the development of the Elasmobranch fishes, with five excellent plates and many woodcuts.—Mr. P. H. Carpenter makes remarks on the anatomy of the arms of Crinoids, his results being arrived at from sections of decalcified specimens.—Dr. Foster describes some effects of Upas Antiar on the frog's heart, demonstrating that the resulting tetanus is brought about by an extraordinary prolongation of the diastole, and not by a too rapid sequence of beats. The arguments for and against the existence of both accelerator and inhibitory fibres in the heart are discussed, in relation with the influence of antiar; and the assumption of the existence of specific accelerator fibres is shown to be unnecessary.—Dr. Curnow notes variations in the arrangement of the extensor muscles of the fore-arm.—Dr. Brunton explains a simple method of demonstrating the effect of heat and poisons upon the heart of the frog.—Mr. G. A. Berry and Prof. Rutherford note with reference to Pflüger's law of contraction, that the excitability and length of the portion of nerve traversed by the voltaic stream must be taken into account in studying the changes of the electrotonic state.—Prof. Rutherford notes with regard to the action of the internal intercostal muscles, their elevating action, as rendered evident by binding similarly situated elastic bands to the ribs themselves.—Mr. Reoch has a paper on the oxidation of urea.—Mr. R. Hughes describes an improved freezing microtome, in which ether spray is the cold-producer.—Dr. S. Coupland records an example of Meckel's diverticulum in man.—The Report on Physiology, by Dr. Stirling, concludes the number.

Poggendorff's Annalen der Physik und Chemie. Ergänzung, Band vii. Stück 2.—In this number is concluded M. Voigt's paper on determination of the constants of elasticity of rock salt; the case of torsion being here dealt with. Comparing his general results with Navier and Poisson's theory, he finds they contradict it in some points, *e.g.* the crystals of the regular system do not behave, in reference to elasticity, like uncrystalline media; for the bending and torsion coefficients are *not* independent of the direction; the constants also have different relative values.—M. Obach describes some interesting experiments on the behaviour of amalgams and metallic alloys under the galvanic current. He finds (1) that the current does not produce in either electrolytic separation of the constituents; (2) that sodium amalgam, after being traversed by the current, decomposes water at both poles as before; (3) that action of the current alters neither the hardness nor malleability of tin-lead alloys, nor the liquid state of potassium-sodium alloy. It works in the chemical composition of the alloy near the electrodes no changes exceeding errors of experiment and analysis. In all these points the author opposes M. Gerardin, who, a short time ago, published experiments on the subject. As to the electric currents occurring in amalgamation of metals, M. Obach regards them as thermo-electric currents due to the temperature changes produced by amalgamation.—M. Clausius contributes a lengthy memoir on the proposition of the mean ergal and its application to the mechanical motions of gases; and a paper by M. Weinberg treats of the application of the mechanical equivalent of heat to molecular forces, size, and distance.

Zeitschrift der Oesterreichischen Gesellschaft für Meteorologie, Jan. 1.—An article extracted from the Proceedings of the Vienna Academy, containing the results of Prof. Kerner's studies and observations, in the neighbourhood of Innsbrück, on the abnormal rise of temperature with increasing elevation in the valleys of the Alps in late autumn and in winter, occupies nearly the whole of this number. The phenomenon occurs every year without fail in this district, and has been observed in Carinthia, Upper Austria, the Tyrol, and Switzerland. The number of farmhouses upon the mountain sides at an inconvenient distance from the pastures below shows that the inhabitants are well aware of the milder climate to be found at moderate altitudes. While frost reigns in the valleys and trees are leafless, the grass and trees upon the heights frequently keep beautifully green, and flowers that bloom elsewhere in autumn and even in spring bloom in the genial air. The valley folk say at such times that the south wind blows aloft and will soon descend to them. Prof. Kerner acknowledges the plausibility of this notion, but gives good reasons for believing it to be ill-founded. It is true that the equatorial current does descend upon the valleys, gradually displacing the polar, but in the first half, at least, of the period of reversed temperature, none of the signs of a south wind appear in the atmosphere, barometric pressure keeps very high, and the sky clear. The latest uncommonly long spell of seventeen days with reversed temperatures, from Oct. 25 to Nov. 10, 1874, enabled Herr Kerner to ascertain the real cause of the strange and hitherto perplexing phenomenon. From an ascent of the Unnutz (2,111 metres), he learnt that the warm region in every valley lies between two cold regions, whose borders differ in position in every valley. The situation of the nether border of the warm region certainly depends on the height of the bottom of the valley. He reached this border at about 200 metres above the level of the Inn, or 700 metres above the sea, and passed out of the warm region into an atmosphere colder than that of the valley at 1,890 metres above the sea. In crossing the Achnenthal at 950 metres, there was a fall of the thermometer, which was soon succeeded by a rise as he continued to climb. In descending the favoured slopes of the mountain he observed several kinds of flowers, some of which generally come out in spring; but a little lower all vegetation was sprinkled with hoar frost. In making his ascent on the sunny side an upward current accompanied him. On the summit a very slight air came from N.E. as long as the sun kept high. Late in the afternooon it had risen to a fresh breeze, and after sunset the N.E. wind was violent. He then made a short descent on the N.E. slope to about 30 or 40 metres from the top. Here he found a calm, and a little lower a breeze blowing down towards the valley. It appeared accordingly that the polar wind divided itself near the top into two streams, one of which turned down into the valley, while the other flowed over the top and then down into the other valley at the foot of the southern slope. This distribution of

currents seemed to him to point to a reason for the existence of a warm region, like that which Herr Hann found for the high temperature of the Föhn wind, namely, that in descending the cold air becomes condensed, and by condensation raised in temperature. From 4 P.M. on the 4th to 5 P.M. on the 5th of November, 1874, readings of the temperature were taken by four observers at Innsbruck (575 metres), Rumer Alpe (southern slope, 1,227 metres), Heiligwasser (northern slope, 1,239 metres), and at the summit of the Blaser (2,240 metres). The mean temperatures for the twenty-four hours at these stations were respectively, 2·16, 7·06, 4·26, and − ·64. The lowest night temperature at Innsbrück was − 2·8; on the Rumer Alpe, + 2·4. The minimum was reached at Innsbrück, just before sunrise, but on the Rumer Alpe at 3.30 A.M.; at sunrise at this elevation the thermometer marked 4·4. At Heiligwasser the same kind of relation was noted, and temperature rose after 4 A.M.; but the maximum by day was much lower than at Innsbruck. The high temperature at this station was not due to heating of the ground by sunshine, for a thermometer fixed on the surface of the soil never rose above 1° C. The wind blew uninterruptedly towards the valley, down the mountain side. There remains but one explanation, namely, that the increasing pressure raises the temperature of the air as it descends. Prof. Kerner proceeds to a more detailed analysis of the distribution of currents over hill and valley both by day and by night, illustrating his theory by diagrams. After sunset the ground of the valley and the air above it cool rapidly by radiation. The air thus made specifically heavy cannot flow off, but rests like a lake at the bottom of the valley. The current which has flowed down the mountain sides being raised in temperature, glides over this stratum, and rises about the middle of the valley, to rejoin the polar wind aloft. By day the air ascends from the valley up the southern slope, and is replaced by a current descending the opposite mountain face. Obviously, the phenomenon of increasing temperature with increasing height must be most striking where the ridges and valleys stretch from west to east, and during periods of polar wind, when the sky is clear and radiation strong.

Der Naturforscher, January.—This number contains an account of observations by M. von Schleinitz, on board the *Gazelle*, when on the transit expedition to Kerguelen's Land, of changes of temperature and specific gravity of water in the southern Indian Ocean. His conclusions are briefly these:—1. Ocean currents, with the exception of the currents caused by regular winds, are due to differences in absolute specific gravity of different parts of oceans, and a small difference produces a strong current. 2. The differences in saltness of tropical and cold seas (in relation to absolute specific gravity), acting oppositely to the temperature differences, moderates ocean currents, which would otherwise be so strong in meridional directions that navigation would be impossible. 3. There is probably a zone where the differences in saltness compensate the differences in temperature, so that waters of different temperature and different saltness may be near each other in equilibrium, *i.e.*, without perceptible current. In the western part of the Indian Ocean this zone is between 40° and 45° S. lat.—There is a notice of two recent series of researches by M. Voigt and M. Groth (conducted by quite different methods), on the elasticity of rock salt; it is shown that in regular crystals the co-efficient of elasticity, and therewith the velocity of sound, is a function of the direction; and that both vary, in accordance with Neumann's theory, symmetrically with reference to the planes of symmetry of the crystal.—M. Frank calls attention to the action of light on the opening of some catkin-like blossoms.—From experiments by M. Luchsinger, it appears that glycerine injected under the skin of animals has an arresting action on the fermentative formation of sugar from the glycogen of the liver.—The remaining papers do not call for notice here.

Jahrbücher für Wissenschaftliche Botanik. Herausgegeben von Dr. N. Pringsheim. Zehnter Band, Drittes Heft, Mit. 11, Tafeln (Leipzig: Verlag von Wilh. Engelmann, 1876).—The present number of Pringsheim's well-known "Year-book" contains three papers, all of great value. The first is by Dr. George Winter, on the genus Sphæromphale and its allies (with three plates). Kœrber in criticising the Schwendener-Bornet theory of lichens, stated that Sphæromphale had only greenish-brown microgonidia, and that the spores did not produce hyphæ. Both these statements are shown to be erroneous, and after a careful anatomical and morphological examination of numerous original specimens, dried and recent, of Sphæromphale and its allies, he groups them together under a single species, *Polyblastia umbrina* (Whlnbg.), Winter, and adds nearly three pages of synonyms!—an eloquent tribute to the species-making capabilities of modern Lichenographers.—The second paper is by Dr. A. Engler, Contributions to the knowledge of the formation of the anther in Metasperms. This paper, which is illustrated with five plates, describes the following subjects: (1) the anthers and pollen of the Mimoseæ; (2) the anthers of Orchidaceæ; (3) the anthers of Asclepiadaceæ; (4) on the so-called introrse and extrorse anthers; (5) on certain apparent departures from the type in the formation of stamens; and (6) on the homologies between stamen and carpel.—The third paper is by Dr. J. Reinke, Contributions to the knowledge of Fucaceæ and Laminariæ (with three plates). The anatomy and external construction of several genera and species are detailed, the most interesting portion of the paper being the paragraphs devoted to secondary circumferential growth in Fucaceæ, and to the formation of adventitious buds.—The illustrations are excellent as usual, and the high character of the *Jahrbücher* well sustained.

Bulletin de l'Académie Royal des Sciences, Nos. 9 and 10, contains an article by Van Beneden on the Pachyacanthus in the Museum at Vienna. The description of other marine mamifers in other museums is to follow, and the whole are to form an introduction to the descriptions of the allied fossil forms discovered in excavations near Antwerp.

SOCIETIES AND ACADEMIES

London

Royal Society, April 6.—"Experiments on the Friction between Water and Air." By Dr. Ritter von Lang. Communicated by N. Story Maskelyne, F.R.S., Keeper of the Mineral Department, British Museum.

The method adopted for estimating the mutual friction of water and air consisted in connecting a glass tube of 8 centims. in length and 0·72 internal diameter with the pipes which supply Vienna with water at a pressure of four atmospheres. Arrangements for securing a vertical position for the tube ensure a perfectly continuous jet, devoid of any broken surface; and a tube surrounding this jet, with its axis coinciding with that of the jet, acts as an aspirator into and along which air is drawn through a lateral feeding-tube. The amount of this in-drawn air corresponding to the fall of a given amount of water was determined by observing the rate at which a film of soap was borne along the feeding-tube; and the velocity of the water causing the in-draught was calculated from the diameter of the water-column and the quantity of water discharged along it in a given time; but after having once determined the form of the slightly conical water column, the amount of water discharged was the only datum required for the calculation.

The influence of a greater or less section of the air feeding-tube on the volume of the aspirated air was carefully determined, while also the absence of any appreciable retardation due to the soap-film was established.

Neglecting the slightly conical character of the surface of the water-column, and assuming (as the result of experiments in which the motion of a smoke-cloud was observed) that the movement of the air was throughout in lines parallel to the axis of the tube along which it flowed, and showing that the pressure does not vary along the length of the tube, the author proceeds to discuss the hydrodynamic equations expressing the conditions of the problem (the motion of the air being uniform and independent of time), and represents the volume of air A passing through the tube in a second as

$$A = W\left[\frac{R^2 - r^2}{2r^2(\log R - \log r)} - 1\right],$$

W being the weight of water, in grammes, discharged in a second, r the radius of the jet in turns of the micrometer-screw (6·8 turns of which correspond to 1 centim.), R being the radius of the aspirating tube.

The results obtained by observation accorded well with those given by this equation, so long as the value of R did not exceed the limit within which the suppositions regarding the motion of the air hold good.

The question whether the results might not be brought into even closer accord with theory by the assumption that a slipping action takes place between the air and the water-jet on the one hand, and between the air and the tube on the other, instead of the assumption previously made that the air adhered

alike to the water and to the tube in its passage. The result of the calculation, however, led to no nearer approximation; and finally, experiments with other materials for the tube and other gases (namely, coal-gas and carbonic anhydride) were made without resulting in any marked difference from the results obtained with air and glass.

Mathematical Society, April 13.—Prof. H. J. S. Smith, F.R.S., president, in the chair.—Prof. Henrici, F.R.S., having taken the chair, the President gave an account of a note—"Sur une théorème d'Eisenstein"—by M. Charles Hermite. This is the celebrated theorem, considered by M. Heine, on the development in a series of the roots of an algebraic equation $f(y, x) = o$. M. Heine has added the very important remark that we can make all the coefficients of such a development, supposed commensurable, integers, with the exception of the first by changing x into $k x$ (Crelle, Band 48, p. 267). M. Hermite's communication gives a simplified proof of this. —Prof. Smith then spoke on the aspects of circles on a plane or on a sphere. He pointed out the connection between his results and those obtained by Prof. Cayley in his researches on trees. He next made some remarks on a problem in crystallography.—Mr. Tucker read part of an abstract (drawn up by Dr. Hirst, F.R.S.) of a paper on correlation in space, by Prof. Rudolf Sturm, of Darmstadt. The paper is connected on the one hand with Sturm's previous one on projectivity in space (*Math. Ann.*, vol. vi.), and on the other with Dr. Hirst's papers on the correlation of two planes, and two space. (*Proc. of Math. Soc.*, vols. v. and vi.)

Chemical Society, Prof. Andrews, F.R.S., in the chair.—A paper on the manufacture of sulphuric anhydride, by Dr. R. Messel and Dr. W. Squire was read by the latter. The authors prepare the anhydride by decomposing ordinary sulphuric acid at a white heat into water, oxygen, and sulphurous anhydride, removing the water by suitable means and then passing the mixed gases over platinised pumice heated to low redness; the oxygen and sulphurous anhydride then reunite to form sulphuric anhydride.—After this paper there was an adjourned discussion on Dr. H. E. Armstrong's paper on systematic nomenclature read at the last meeting, in which Prof. Odling replied at length to the criticisms on the article recently published by him on the same subject in the *Philosophical Magazine*.

Royal Astronomical Society, April 12.—Mr. Wm. Huggins, D.C.L., president, in the chair.—J. Bagnold Smith, Sir David Solomons, W. T. Smedley, Wm. Durrad, Wm. Allsup, and the Rev. Joseph Ferguson were elected Fellows of the society.—Mr. Penrose described an instrument for calculating the sides and angles of spherical triangles. It consisted of two wooden semicircles which could be fixed at any angle, and a graduated arm moving on a universal joint which slid along one of the semicircular arcs. The graduated arm was made use of to measure the cord of the third side of the triangle. Mr. Penrose showed how the instrument might be made use of for roughly checking calculations in spherical trigonometry. He thought that it would also be of use in expeditiously reducing observations in which no great degree of accuracy was required. The instrument was very portable and might be made still more so if the graduated semicircles were divided on brass instead of on wood, as in the instrument he showed. A paper by the Rev. T. W. Webb was read describing some observations of the two exterior satellites of Uranus which had been made by Mr. Isaac Ward of Belfast. Mr. Ward's instrument is a refractor of only 4·3 inches aperture, but he had apparently succeeded on some dozen evenings during the months of January, February, and March, in picking up both the outer satellites Titania and Oberon. A table was given comparing the position angles and distances as estimated by Mr. Ward with those taken from Mr. Marth's ephemeris of the satellites. It was stated that the estimates of Mr. Ward had been made without any previous reference to the ephemeris, the coincidences were such that there seemed little room left for doubt that Mr. Ward had in each instance been successful in picking up the satellites. Mr. Lassell said that he had not seen the satellites with his own nine-inch. It was quite possible that the extraordinary sharpness of Mr. Ward's eye might have enabled him to pick up the satellites; there were records which could not be doubted of persons who had observed the satellites of Jupiter with the naked eye. He thought that if any one else made use of the same telescope they would certainly not be able to detect the satellites.—Mr. Green drew the attention of observers to the visibility of the dark limb of Venus during the coming quadrature; he had on many occasions thought that he perceived the dark limb on a brighter background, but on placing the bright limb of the planet behind a dark bar in his eye-piece, he had entirely lost sight of the dark limb. He wished that other observers would try the same experiment during the coming quadrature. The meeting adjourned till May 12.

Geological Society, April 5.—Prof. P. Martin Duncan, F.R.S., president, in the chair.—James Mansergh, M. Inst. C.E., was elected a Fellow of the Society.—On the bone-caves of Creswell Crags (second paper), by the Rev. J. Magens Mello. In this paper the author gives an account of the continuation of his researches upon the contents of the caves in Cresswell Crags, Derbyshire. The further exploration of the Pin Hole cave described in his former paper,[1] furnish a few bones of Reindeer, *Rhinoceros tichorhinus*, and other animals, but no more remains of the Arctic Fox, which were particularly sought for. Operations in this cave were stopped because the red sand in which the bones were found towards the entrance became filled with limestone fragments, and almost barren of organic remains. The author then commenced the examination of a chambered cave called Robin Hood's cave, situated a little lower down the ravine on the same side. The section of the contents of this cave showed a small thickness of dark surface-soil, containing fragments of Roman and mediæval pottery, a human incisor, and bones of sheep and other recent animals; over a considerable portion a hard limestone breccia, varying in thickness from a few inches to about 3 feet; beneath this a deposit of light-coloured cave-earth, varying in thickness inversely to the breccia, overlying a dark-red sand about 3 feet thick, like that of the Pin Hole, but with patches of laminated red clay near the base, and containing scattered nodules of black oxide of manganese, and some quartzite and other pebbles, which rested upon a bed of lighter-coloured sands containing blocks of limestone, probably forming part of the original floor of the cavern. The hard stalagmitic breccia contained a great many bones, chiefly of small animals, but with some of reindeer, and teeth of *Rhinoceros tichorhinus*, hyæna, horse, water vole, and numerous flint-flakes and chips, and a few cores. Some of the flakes were of superior workmanship. A few quartzite implements were also found in the breccia. The cave-earth contained a few flint implements, but most of the human relics found in it were of quartzite, and of decidedly palæolithic aspect. There was also an implement of clay-ironstone. The animal remains chiefly found in the cave-earth were teeth of horse, *Rhinoceros tichorhinus*, and hyæna, and fragments of both jaws of the last-mentioned animal. Bones and teeth of reindeer and teeth of cave-lion and bear also occurred. The red sand underlying the cave-earth contained but few bones, except in one place, where antlers and bones of reindeer and bones of bison and hyæna occurred. At another part a small molar of *Elephas primigenius* was found. A large proportion of the bones had been gnawed by hyænas, to whose agency the author ascribed the presence of most of the animal remains found; but he remarked that no coprolites of hyænas had been met with. The following is a list of the animals whose remains occurred in this cavern:—*Felis leo* (var. *spelæa*), *Hyæna crocuta* (var. *spelæa*), *Ursus arctos*, *U. ferox*, *Canis familiaris*, *C. lupus*, *C. vulpes*, *Elephas primigenius*, *Equus caballus*, *Rhinoceros tichorhinus*, *Bos bison*, var. *priscus*, *Bos longifrons*, *Capra hircus*, *Sus scrofa*, *domesticus*, and *ferox*, *Cervus megaceros*, *C. tarandus*, *Arvicola amphibius*, and *Lepus timidus*.—On the mammalia and traces of man found in the Robin Hood Cave, by Prof. W. Boyd Dawkins, F.R.S. The author noticed the various species of animals discovered by Mr. Mello during the researches, the results of which are given in the preceding paper, and drew certain conclusions from their mode of occurrence as to the history of Robin Hood's Cave. He considered that the cave was occupied by hyænas during the formation of the lowest and middle deposits, and that the great majority of the other animals whose remains occur in the cave were dragged into it by the hyænas. That they served as food for the latter is shown by the condition of many of the bones. During this period the red sand and clay of the lowest stratum was deposited by occasional floods. The red loam or cave-earth forming the middle stratum was probably introduced during heavy rains. The occupation of the cave by hyænas still continued, but it was disturbed by the visits of palæolithic hunters. The remains found in the breccia indicate that the cave was inhabited by man, and less frequently visited by hyænas than

[1] See Quart. Journ. Geol. Soc., vol. xxxi. p. 679.

before. The presence of vertebræ of the hare in the breccia would imply that the hunters who occupied the cave had not the dog as a domestic animal. After a discussion of the relations of the animals forming the fauna of the cave, the author proceeded to describe the traces of man found in it, which consist of fragments of charcoal, and implements made of antler and mammoth tooth, quartzite, ironstone, greenstone, and flint. The distribution of these implements in the cave represents three distinct stages. In the cave-earth the existence of man is indicated by the quartzite implements, which are far ruder than those generally formed of the more easily fashioned flint. Out of 94 worked quartzite pebbles only three occurred in the breccia, while of 267 worked flints only 8 were met with in the cave-earth. The ruder implements were thus evidently the older, corresponding in general form with those assigned by De Mortillet to "the age of Moustier and St. Acheul," represented in England by the ruder implements of the lower breccia in Kent's Hole. The newer or flint series includes some highly-finished implements, such as are referred by De Mortillet to "the age of Solutré," and are found in England in the cave-earth of Kent's Hole and Wookey Hole. The discovery of these implements considerably extends the range of the palæolithic hunters to the north and west, and at the same time establishes a direct relation in point of time between the ruder types of implements below and the more highly-finished ones above.—Notes on the gravels, sands, and other superficial deposits in the neighbourhood of Newton-Abbot, by Horace B. Woodward, F.G.S. The writer pointed out that most of the deposits termed Upper Greensand in the immediate neighbourhood of Newton-Abbot, were in reality intercalated with coarse gravel-beds, containing, among others, fragments of greensand, chert, and chalk-flint. He considered that the only traces of greensand *in situ* were probably on the summit of Milber Down and east of Combe Farm, deposits which were identified by Mr. Godwin-Austen. But he could not agree in the identification of greensand at other localities in the Bovey Valley, considering the few fossils found to have been derivedt rom, and with much other material to have been evidently due to ,the denudation of chalk and greensand. He pointed out the geographical distribution of these beds of sand and gravel, which extend from the hill-tops bordering the Bovey Valley to near the bottom of the valley, but do not descend into any outlying valleys. He likewise alluded to the peculiar dip into the valley which affects these beds in several places, and observed that sometimes they rested on the Bovey clays and lignites. He thought some connection in their method of formation might be traced with somewhat similar deposits on the Haldon and Black Down Hills. He pointed out the "Head" at the bottom of the valley was sometimes not to be distinguished from the older gravels, from which, however, it was largely derived. He alluded to the discovery of bones, a bronze spear-head, and a wooden doll or idol in this deposit; observing that they indicated the rapid accumulation of gravel, and that this indication was one out of many that might be given, that our modern river-gravels are to a great extent made up of older gravels. In conclusion the writer alluded to some of the deposits now forming on the margin of the Teign estuary, and which are identical in character with the Triassic breccia.—On certain alluvial deposits associated with the Plymouth limestone, by R. N. Worth, F.G.S. The author adduced certain deposits found in fissures and caverns of the Plymouth limestone, as furnishing evidence in opposition to the views advocated by Mr. Belt in his paper on the drifts of Devon and Cornwall.[1] The best examples occur at Plymouth Hoe, where the chief deposit fills a large "pocket" in the limestone, and consists (beneath the turf) of a bed of clayey soil, containing pebbles and small boulders, beneath which are patches of white and red clay, containing a few pebbles, and overlying a large quantity of siliceous sand. Similar, but slightly varying deposits, not unfrequently occur in association with the limestone; and these are regarded by the author as the remains of considerable deposits which once occupied large areas in the valleys of South Devon; and if they are not the lowland gravels of Mr. Belt, the latter are not represented in the district. The author states that there is evidence of the contemporaneity of these deposits with those of the Oreston caves; and he adds that they furnish no proof of cataclysmal action, but of orderly deposition, the bulk of the pebbles and gravels being inland nearer the source of the *débris*, and further off the sands and clays in fairly regular succession. The author further explains the presence in Cornwall of stanniferous gravels only in valleys opening to the south, by reference to the position of the watershed in that county, which has only two rivers running to the north, whilst on the south-east rivers abound.

[1] See "Quart. Journ. Geol. Soc.," vol. xxxii., p. 80.

Physical Society, April 8.—Mr. W. Spottiswoode, vice-president, in the chair.—Mr. H. M. Klaassen was elected a member of the Society.—Prof. Foster exhibited and described an instrument for illustrating the law of refraction. It is founded on the well-known method of determining the direction of the ray after refraction by means of two circles described from the point of incidence as centre, the ratio of whose radii is the index of refraction. If the incident ray be projected to meet the inner circle, and through the point of intersection a vertical line be drawn, the line drawn from the point of incidence to the point where this meets the outer circle is the direction after refraction. This principle is applied in making a self-adjusting apparatus as follows:—A rod representing the incident ray is pivoted at the point of incidence, and projects to a point about 4 inches beyond. To this extremity is attached a vertical rod which slides through a nut in another rod also pivoted at the point of incidence. The lower extremity of the vertical rod is attached to a link, so fixed as to constrain it to remain vertical. By this means the two rods always represent respectively the incident and refracted rays, and the index of refraction can be varied by altering the position of the nut, through which the vertical rod passes, on the rod to which it is attached.—Prof. Foster then exhibited a simple arrangement for showing the interference of waves. It consists of two glass plates placed one in front of the other, on each of which is drawn the ordinary sine wave. They are supported in a frame, and behind them is a paper screen bearing lines to indicate the points of maximum and minimum displacement. The plates can be made to slide in opposite directions, and all the phenomena of wave motion generally, and the state of the air in open and closed tubes can be shown. Lastly he exhibited a method, which has been suggested by Prof. Kundt, for showing in a simple manner that the air in an organ pipe is in a constant state of alternate condensation and rarefaction. At the upper end of a closed pipe are placed two valves opening inwards and outwards respectively, and the chambers behind these are connected by india-rubber tubes with small water-gauges which, for the sake of exhibition, were projected on the screen. The guages were to the eye permanently set, showing at the same time condensation and rarefaction, an appearance which was of course due to the rapidity of change. It was shown that beats cause the air to approximate to its normal density.—Prof. Guthrie exhibited and described an arrangement which he thought might be useful for determining the rate at which machinery is revolving. The instrument is analogous to one which he devised some years ago for rendering a galvanic current constant. The chamber of a manometer is connected with a small force-pump, which makes one complete stroke for every revolution of the engine. A capillary glass tube affords a means of escape for the air introduced by the pump into the manometer. If now the pump be worked uniformly, that is if the engine rotates uniformly, the pressure in the manometer will shortly attain a position of equilibrium, so that the mercury will remain stationary. But if the velocity of the engine increase, the mercury will immediately ascend, and so indicate this increase of speed. The main objection to the instrument, as exhibited, was the oscillation of the mercury, but this might be avoided in several ways which were pointed out.—Mr. Coffin referred to some works in America where he had seen a similar principle applied. The engine was connected with an air chamber, to which was applied a Bourdon's gauge, the indications of which gave an approximate measure of the revolutions of the engine.—Prof. Unwin thought there would be some difficulty in keeping the capillary orifice perfect for any length of time. He referred to a proposal made by Prof. Thomson in about 1852 to use a centrifugal pump for a similar purpose.

Anthropological Institute, April 11.—Col. A. Lane Fox, president, in the chair.—Five new members were announced.—A note on some suggested archæological symbols for maps, by Mr. Joass, was read by Capt. Dillon.—Dr. Comrie, R.N., read a paper entitled "Anthropological Notes on the Natives of New Guinea," being the result of his observations while attached to H.M.S. *Basilisk*, engaged surveying there. The physical, social, and religious character of the Papuans were discussed, and the probable Polynesian intermixture and origin of the natives of New Guinea considered, the author inclining to the opinion that the Papuan was a pure type of race, the most characteristic fea-

ture next to language being the tape-like flattening of their hair noticeable in an ordinary lens. The paper was accompanied with a comprehensive exhibition of Papuan weapons, works of art, utensils, and articles of dress, which will remain at the Institute till their next meeting, April 25, when the discussion, in which Col. Fox, Lieut. Armit, R.N., Mr. Franks, Mr. Hyde Clarke, the Rev. A. H. Sayce, and others took part, will be continued.—Mr. Brabrook, the Director, then read a paper by Mr. B. Walker entitled "Religion, Politics, and Commerce of Old Calabar," which contained an account of the singular institution of Egbo, the principal object of which is to secure mutual protection amongst the freemen. Admission to the various grades, nine in number, is by purchase. As regards religion each district has a separate but subordinate divinity. Their commerce consists of palm oil, ebony, ivory, and barwood. The inhabitants appear to be advancing in civilisation.

Entomological Society, April 5.—Prof. Westwood, president, in the chair.—Messrs. J. W. Douglas, E. C. Rye, G. Lewis, C. Fenn, J. Dunning Kay, and W. C. Copperthwaite were elected Ordinary Members; and Mr. B. A. Bower, jun., was elected a Subscriber.—Mr. F. Bond exhibited a specimen of *Xylina lambda* taken near Erith in September last by Mr. W. Marshall, being the fifth instance of its having been taken in Britain. He also exhibited *Ebulea stachydalis*, taken by himself at Kingsbury, Middlesex, in June 1862.—Mr. Champion exhibited specimens of *Ægialia rufa*, taken by Mr. Sidebotham near Southport, and he brought examples of *Psammodius sulcicollis* for distribution.—The President made some observations respecting the habits of the common gnat, in continuation of his remarks at the meeting of Nov. 4, 1872. Large numbers of females had again appeared in his house at Oxford, not a single male having been observed, and he believed they had hibernated in the house, appearing the first warm days of spring. He also remarked that Dr. Leconte's valuable collection of *Coleoptera* had been presented to the University of Cambridge, Mass.—Sir Sidney S. Saunders exhibited living specimens of *Stylops Kirbii* taken by himself at Hampstead; altogether he had found eighteen males. Mr. Enock also exhibited a row of eleven males taken on the wing at the same place and about the same time.—The Rev. A. E. Eaton stated that he was preparing a supplement to his monograph of the *Ephemeridæ* (*Trans. Ent. Soc.*, 1871), chiefly from materials in the collections of Mr. McLachlan and Mr. Albarda, and that he would be glad of any assistance that could be given him by entomologists possessing insects belonging to that group. It appeared that the deficiency in legs in *Campsurus* and some of its allies was due to their being shed with the pupa skin when the insect obtains well-developed wings, and that in some forms all the legs were thus cast off by the female.—Mr. Smith made remarks on the distribution of some genera of Hymenopterous insects from New Zealand, of which a collection had been placed in his hands by Mr. C. M. Wakefield; and was followed by Mr. McLachlan, who remarked on the gradual extinction of the endemic fauna of New Zealand, although introduced forms throve wonderfully.—The Rev. R. P. Murray stated that he was preparing a list of the species of Japanese butterflies, and that he would be grateful to any entomologist who could assist him with the loan of specimens.—Mr. McLachlan exhibited a series of *Anomalopteryx Chauviniana*, Stein., from Silesia, given to him by the discoverer of the species, Fräulein Marie von Chauvin, of Freiburg. This singular Trichopterous insect pertained to the family *Limnophilidæ*, and was remarkable for the lanceolate anterior, and abbreviated posterior wings of the male; those of the female being normal, excepting that the posterior wings were smaller than usual. Also apterous females of *Acentropus niveus* received from Mr. Ritsema, of Leyden; and a microscopic slide with a full-grown female example of *Phylloxera vastatrix* of the root form. This he had recently obtained, with many others, from a vinery near London, which was terribly infested with the insect.

Meteorological Society, April 19.—Mr. H. S. Eaton, president, in the chair.—T. H. G. Berrey, Assoc. Inst. C.E., H. G. Bolan, J. Bravender, J. Holden, G. A. Hutchins, F. Jackson, J. L. Johnson, B. Latham, A. G. McBeath, W. R. Maguire, A. S. Moss, C. Pink, J. R. Rogers, E. Toller, S. Tomlinson, W. A. Mc I. Valon, H. Walker, W. E. Woolley, were elected Fellows of the Society. The following papers were then read:—Velocity of the wind at Liverpool, tabulation of anemometric records, by W. W. Rundell; on the aspiration of the dry and wet bulb thermometers, by Samuel H. Miller, F.R.A.S.; on the storm which passed over the south of England on March 12, 1876, by Robert H. Scott, F.R.S.—The members of the Permanent Committee of the Vienna Meteorological Congress were present and took part in the discussion.

Victoria (Philosophical) Institute, April 3.—Mr. Howard, F.R.S., read a paper on the history of Egypt in connection with the Bible.

ROME

R. Academia dei Lincei, Dec. 5, 1875.—M. Moriggia communicated the results of experiments on the natural poisons of the body, bile and amygdaline.—M. Volpicelli gave a short necrological memoir of Wheatstone.

Jan. 2.—M. Volpicelli described the construction, properties, and applications of a constant inductor.—M. Sella gave the composition of various salt springs in Italy.—M. Capellini presented a paper on Tuscan fossil whales.—M. Castaldi communicated a note on fossils from the dolomitic limestone of Monte Chaberton, studied by M. Michelotti.—M. Cossa described the periclasiferous predazzite of Monte Somma.—M. Canizzaro reported on a memoir by MM. de Negri on the purples of the ancients; also on a memoir by M. Paterno, on usnic acid and on two new principles accompanying it in *zeora sordida*; also on one by M. Selmi, on toxicological chemical studies relating to atropine and its detection.—M. Struver communicated a memoir on the minerals of Lazio.
